LOGICAL POSITIVISM, a philosophical doctrine first formulated in Vienna in the 1920s, according to which scientific knowledge is the only kind of factual knowledge and all traditional metaphysical doctrines are to be rejected as meaningless. The school differs from earlier empiricists and positivists (David Hume, Ernst Mach) in holding that the ultimate basis of knowledge rests upon public experimental verification rather than upon personal experience. It differs from Auguste Comte and J. S. Mill in holding that metaphysical doctrines are not false but meaningless—that the "great unanswerable questions" about substance, causality, freedom and God, are unanswerable just because they are not genuine questions at all. This last is a thesis about language, not about nature, and is based upon a general account of meaning and of meaningfulness. All genuine philosophy (according to the Vienna group) is a critique of language; and (according to some of its leading members) its result is to show the unity of science—that all genuine knowledge about nature can be expressed in a single language common to all the sciences. Philosophy is not a theory but an activity. The proper task of philosophers is linguistic—unless we add that it is their business also to persuade men to adopt a "scientific" attitude to moral and political questions.

The Vienna circle, which launched its first manifesto in 1929, had its origin in discussions among physicists and mathematicians before World War I. The general conclusion was reached that the empiricism of Mill and Mach was inadequate since it failed to explain mathematical and logical truths, or to account satisfactorily for the apparently *a priori* element in natural science. In 1922, Hans Hahn at Vienna university laid before his students the *Tractatus Logico-Philosophicus* of Ludwig Wittgenstein, published in the previous year. This work introduced a new general theory of meaning derived in part from the logical inquiries of Giuseppe Peano, Gottlob Frege, Bertrand Russell and A. N. Whitehead. It gave the Vienna group its logical foundation and drew in the philosophers Moritz Schlick, Rudolf Carnap, Friedrich Waismann, Otto Neurath and (at Berlin) Hans Reichenbach and Walter Dubislav. The group conducted its campaign in the journal *Erkenntnis* (Leipzig, 1931-40) and, after most of the members of the group had moved to the United States, in an elaborate *International Encyclopedia of Unified Science* (Chicago, 1938 *et seq.*), published with the help of Charles Morris and other U.S. associates. Carnap at Chicago, Reichenbach in California, Philipp Frank at Harvard, Waismann in England and many others, continued the work of the school in a series of systematic works and a stream of papers and monographs. In the meantime disciples had been found in many other countries: in Poland, among the mathematical logicians; and in England, where A. J. Ayer's *Language, Truth and Logic* (1936; rev. ed., 1946) provided an excellent introduction to the views of the group. In England, however, the direct influence of Wittgenstein proved very much more powerful. Witt-

genstein had come to England from Austria before World War I and had spent some time at Cambridge, discussing logic with Bertrand Russell. The *Tractatus Logico-Philosophicus* expresses and generalizes the conclusions that he had reached upon philosophical questions. In 1929 Wittgenstein returned to Cambridge and taught and worked there (with a few intermissions) until his retirement in 1947. During this later period Wittgenstein himself subjected the doctrines of the *Tractatus* to fundamental criticism and produced what was in effect a new account of philosophy. The later philosophy was disseminated by his students (and by copies of his own informal notes) and profoundly affected the course of English philosophical thought. His *Philosophical Investigations* (Ger. text with Eng. trans., 1953) appeared posthumously. While the name "logical positivism" is commonly applied to Wittgenstein's later philosophy as well as to the *Tractatus*, it is certain that a wide gulf separates it from the philosophy which the Vienna circle based in part upon the *Tractatus*.

Characteristic Views of the Vienna Circle.—The following views may be regarded as characteristic of the Vienna school:

Philosophy as a Critique of Language.—It is evident that some of the great philosophers (Locke, Spinoza) explicitly undertook the criticism of language, but it has generally been held that this was not their chief task. Philosophers have usually attempted to assert a view about the world; to state not only the limits of the possible, but also the nature of being or of the universe as we know it. Wittgenstein's *Tractatus* attempted to show that reality as a whole cannot be described and that the limits of the possible (or "of what can be said") are shown in the language as a whole. But what is shown in the language as a whole cannot itself be said in language. According to the Vienna school the traditional metaphysical philosophies purport to ask the questions that cannot be answered (e.g., Can one really know material substances?). Here, although experimental evidence may seem to be relevant, it always proves to be beside the point. Metaphysical statements have no verification; metaphysical questions are *Scheinprobleme*. There are of course many questions which philosophers have asked (e.g., about the physiology of perception) which concern particular matters of fact. These however belong to science and not to philosophy. The sole remaining task of philosophy is the analysis and clarification of language. This involves an account of "meaningful" and "meaningless," "true" and "false," "valid inference," etc. as these terms are applied to contingent and to necessary statements—to the propositions of science and history and to the theorems of logic and mathematics. An understanding of such matters will enable us to show how a given metaphysical question arose and why it is meaningless. It is characteristic of the Vienna group, as of the *Tractatus*, that particular metaphysical puzzles are to be settled by reference to a general theory about language.

The Doctrine of Tautology.—This doctrine derives from the *Tractatus*. The only necessary propositions are those which are true by definition; which are so framed that they cannot be denied without inconsistency. Thus "All men are rational" is held to assert with regard to anything that either it is a man or it is not rational. But this follows from our actual use (or one actual use) of "man" and "rational." The necessary proposition cannot but be true since it asserts every possible state of affairs: it is true whichever of its constituents are true and true whichever-so-ever of its constituents are false. There is a sense therefore in which all necessary propositions say the same thing—that is, *nothing at all*. And the Vienna group held that in general any necessary truth is derivable from some rule of language: its only necessity is its being prescribed by rule in a certain system. This was most easy to show in the case of mathematics, but some attempt has been made to codify the physical sciences and even branches of biology. With regard to nontechnical necessary propositions (e.g., "Whatever has a beginning in time must have a cause"; and "The same surface cannot be red all over and blue all over at the same time") it was recognized that our ordinary language is not itself capable of exact formulation as a calculus: but attempts were made to construct an artificial language in which all necessary statements could be demonstrated by appeal to formulas (e.g., Carnap's *Der logische Aufbau der Welt*, 1928).

The Verification Principle.—The fundamental purpose of language is the making of statements about the world. The earlier works of the logical positivists distinguish sharply between "atomic propositions," each of which refers to a single atomic fact, and derivative propositions or hypotheses, which assert some truth-functional combination of atomic facts (e.g., a disjunction of two such facts, a conjunction of a set of such facts). An atomic statement is true if it corresponds to an atomic fact (by which was originally meant a simple observation); a hypothesis is true if the atomic propositions that it asserts are true and the atomic propositions that it denies are false. "The meaning of a statement is the method of its verification" (Waismann). The verification test does not require actual verification but only verifiability in principle, nor is complete verification envisaged in most cases: in all cases it must be possible to collect experimental evidence which determines the truth or falsity of some of the atomic propositions involved (i.e., which tells for or against the hypothesis). The verification test excludes a hypothesis which asserts every possible combination of its atomic constituents: such a "hypothesis" is in fact a tautology or necessary statement. The same test excludes a hypothesis which denies every possible combination: such a "hypothesis" is excluded as being a contradiction or nonsense. But the test also excludes "hypotheses" which do not mean (i.e., from which one cannot validly infer) any set of atomic statements. For where this is the case no evidence is available by which its truth or falsity can be shown. For example, Berkeley argued that the assertion of material substance is nonsensical, since it cannot be "cashéd" in any statements about ideas of sense; whereas the assertion that "a tree exists in the park" or "I have two hands" can be so "cashéd."

Form and Content.—The earlier writers (especially Moritz Schlick) were perplexed by the metaphysical problem of how it is possible to communicate at all if our genuine statements are really about our own experiences. How can I be sure, for example, that another person verifies my statement by reference to the same kind of experience as I do? Schlick attempted to avoid the difficulty by his doctrine of form and content: what we communicate by language is not experience but knowledge, and knowledge is the form of which experience is the content. This very difficult doctrine evidently refers to two striking facts about our common use of language: (1) users of a given language employ a common syntax and a common set of definitions; and (2) they also (generally speaking) apply descriptive words on the same occasions even when their experiences come to them through different senses (sight, touch, etc.). This, it is commonly held, one can know without beginning to know what experiences lead people to make use of the language. Schlick maintained that we understand what a man means (in the only sense in which meaning can be communicated; see also SEMANTICS IN LOGIC) if we know (1) the syntactical connections of his words with related expressions in the language (especially if we know the definition of his terms in terms which are simple or indefinable); and (2) if we know how he uses the simple terms (i.e., on what occasions he would apply them). This communicable meaning is called form: for a given person, no doubt, it is the form of his own experience-content; but while it is nonsense to speak of community of experience, it is not nonsense to speak of community of structure.

Protocol-Statements.—The doctrine of form and content failed to satisfy. Carnap argued that the question of the relation of an expression to experience (or content) is either meaningless or can be translated into a question about the relation of one expression (or type of expression) to another. Thus a question about how an empirical proposition is to be verified (or what it means) ought to be tackled by showing its connection not with experiences, but with statements of a peculiar and fundamental kind, the so-called *Protokollsätze*. Such statements would be described by other philosophers as an observer's account of what he actually perceives at a given moment: Carnap describes them by specifying the kinds of expression that can occur in them. Then the last word about the meaning of an empirical proposition is given in showing the kinds or classes of protocol-statements which (if they were made) would logically entail the truth or probability of the statement. This is

also the last word about its truth, since, according to the theory, it makes no sense to add "provided that the protocol-statements were made truly." For the protocol-statements have to be taken as indubitable: science rests upon the reports actually made by observers. And Carnap improved the occasion by putting forward the general thesis that statements or questions about the relation of language to experience (which belong to the "material mode of speech") are always a source of metaphysical muddle and can always be replaced by statements or questions about the rules connecting one type of expression with another—statements in the "formal mode of speech." From this, Carnap passed later to the development of a hierarchy of languages.

Physicalism.—The doctrine of protocol-statements was subsequently modified. In the first place, the attempt to show the one-sided dependence of all empirical statements upon some set of protocol-statements came to be regarded as a quaint metaphysical survival: Neurath argued that real language knows no vocabulary of direct experience and that the reports which are actually employed in verifying empirical statements are framed in ordinary language. Second, protocol-statements are not indubitable: not only may we have to select between conflicting reports, we may also decide to reject a report rather than modify an empirical theory or generalization. Neurath preferred to view protocol-statements in the same sort of way as the indications of thermometers or measuring rods: that a thermometer records a high temperature and that an observer says he is getting very hot are both facts (if they are facts) about the physical world and expressed in "physical-object-language"; and either may need correction. Science is possible (it was agreed) because in fact the reports of different observers in the same circumstances do in general agree, and because reports made by the same or different observers upon the evidence of different senses (sight, touch, etc.) also in general correspond. Logical positivists (or many of them) thus passed easily from a quasi-phenomenalist philosophy to a quasi-materialistic philosophy, and from a correspondence theory of truth to a coherence theory—modified in some cases by the introduction of arbitrary or conventional choice.

The Emotive View of Ethical Expression.—Having delivered philosophers and scientists from "the misery of metaphysics," the group proceeded to demolish all kinds of philosophical morality—except possibly their own. So-called statements about what things are right or good cannot be verified (in the manner explained above) and are therefore without meaning. They are simply expressions of attitudes and ought not to be regarded as conveying knowledge or even opinion. The characteristic value words may serve to move or to persuade: they cannot serve to convince us of facts, since they are indefinable in factual terms. This view, reminiscent of Hume, had already been put forward in England by C. K. Ogden and I. A. Richards (*The Meaning of Meaning*, 1922). It was more or less generally adopted by the Vienna group and their English and American disciples, although Schlick (*Fragen der Ethik*, 1930) argued at length for a typical hedonistic utilitarianism. The "logic" or methodology of persuasive argument was fully examined by Charles Stevenson (*Ethics and Language*, 1945) more from the point of view of the Cambridge analytical school than from that of the Vienna group.

Particular Doctrines of Wittgenstein.—In the foregoing account of the Vienna group emphasis has been put on Wittgenstein's *Tractatus Logico-Philosophicus*; undoubtedly the general doctrine of tautology and the doctrine that philosophy is analysis of language are to be found in the *Tractatus*. Two other doctrines to be found there received less attention from the Vienna group: (1) the account of how a simple statement means a simple fact—the "relation of representation"—and the general doctrine of how communication is possible by means of different kinds of signs; and (2) the doctrine that tautologies do not say, but only show, the structure of language—that the characteristic structure of language cannot be said in language. Wittgenstein admits a use for the tautological principles of formal logic—while asserting provocatively that contradictions would have served the same purpose—but is prepared to dismiss as nonsense all those philosophical statements in which the structure of language is elucidated or its limits

traced. This self-denying ordinance was not taken seriously by the Vienna group, who attempted to circumvent it by the introduction of the "formal mode of speech" and the hierarchy of languages.

In his later discussions and in the *Investigations*, Wittgenstein denounced all attempts to build systems of philosophy—even negative systems: he declined to offer any general theory of meaning and was particularly mistrustful of theories which take mathematics or natural science as the ideal. It is possible to trace in his later writings analogues of logical positivist principles: for example, that philosophy is a critique of language. But the doctrines are only analogues, and no conclusion can be reached about his views from a study of the writings of the Vienna circle.

Logical positivism in the United States has found allies among the pragmatists and (naturally enough) among the logicians and scientists. The philosophy of Wittgenstein has been associated with the Cambridge school of G. E. Moore (the defense of common sense and of ordinary language) and has a very wide following in England.

See also biographies of philosophers referred to above and references under "Logical Positivism" in the Index.

BIBLIOGRAPHY.—Reference should be made to the works mentioned above, especially to those of A. J. Ayer and to the volumes of *Erkenntnis* (1931-40); also to the periodicals *Journal of Philosophy*, *Philosophy of Science*, *Analysis*, *Mind* and *Australasian Journal of Philosophy*. See also two short works by R. Carnap, *The Unity of Science*, Eng. trans. (1934), and *Philosophy and Logical Syntax* (1935), as well as his massive *Logical Syntax of Language* (1937). M. Schlick, *Gesammelte Aufsätze* (1938), is of importance. Philipp Frank, *Modern Science and Its Philosophy* (1949), gives a history of the movement. See further J. R. Weinberg, *An Examination of Logical Positivism* (1936); and L. S. Stebbing, "Logical Positivism and Analysis," *Proceedings of the British Academy*, vol. xix. Gilbert Ryle, *The Concept of Mind* (1949), and John Wisdom, *Other Minds* (1952), show in contrasted ways the influence of Wittgenstein's later thought. (K. W. B.)

LOGISTICS. In U.S. military administration, a term loosely applied to a wide range of noncombatant activities, especially those connected with supply, transportation, construction and the care and evacuation of sick and wounded. In a nonmilitary sense, long archaic, logistics was the Greek science of computation (from *logistikos*, "skilled in calculating"); it is also a branch of logic closely related to mathematics. Until World War II the term was not generally used outside the United States, but in the 1960s it became increasingly common in defense circles in NATO countries, particularly Great Britain and Canada. Its nearest counterpart in British military terminology is "administration," an even broader term embracing all military activities not directly associated with strategy (*q.v.*) and tactics (*q.v.*). Though still defined in this sense in American military dictionaries, "administration" has been largely replaced by "logistics" in ordinary military usage in the U.S.; when used, "administration" generally has the layman's meaning of "management."

 2. Management
 3. Logistics in Nuclear War

I. CHANGING USES OF THE WORD

In its military sense, the word logistics has been used so loosely, and in such a variety of specific and general applications, as to defy precise definition. For some writers in the late 18th and early 19th centuries it appears to have conveyed such disparate meanings as "strategy" and "philosophy of war." For others in the same period it had come to signify military staff work in general.

1. Jomini.—The first serious effort to define the word with some precision and to fix the place of logistics in the science of war was made by Baron Antoine Henri Jomini (*q.v.*), the celebrated student of Napoleon's campaigns and foremost authority on the military art in the first half of the 19th century. In his *Précis de l'art de la guerre*, published in 1836, Jomini divided the art of war into five branches—strategy, grand tactics, logistics, engineering and minor tactics. Logistics, the third branch, he defined as "the practical art of moving armies," by which he meant not merely the mechanics of transportation, but the staff work, administrative arrangements and even reconnaissance and intelligence involved in moving and sustaining organized military forces. Engineering, defined as the art of fortification, did not include, in Jomini's scheme, nontactical types of construction (building of roads, cantonments, etc.), which presumably came under the heading of logistics. Jomini thought of logistics, in fact, as comprising virtually all military activity, apart from combat and the planning of combat, involved in "the execution of the combinations of strategy and tactics."

In particular, Jomini associated logistics with the work of the military staff. According to him, the word had been derived from the title of the *maréchal* (or *major général*) *des logis* in French armies of the late 17th and 18th centuries, who, like their Prussian counterpart, the *quartiermeister*, had originally been charged with routine administrative arrangements for marches, encampments and troop quarters (*logis*). With the growing complexity of military administration in the 18th century, the more gifted of these officials (like Pierre-Joseph de Bourcet, from whose campaign plans Napoleon later profited) had become the equivalent of chiefs of staff to the high-born and often inept commanders of the day, and had developed an efficient staff system along the lines of the modern general (or "capital") staff. Since Jomini's time, other writers have traced the origin of "logistics" to the title of the *logista*, an administrative official in Roman and Byzantine armies.

The Greek word *logistikos*, mentioned above, also has an obvious functional relationship to it. Whatever the origin of the word, Jomini saw logistics as the central function of the commander's staff, which in his own time had come to play a crucial role in translating the commander's ideas and will into concrete action. Generalship, he insisted, was inseparable from good staff work, and a good general must also be a good logistician. For future generals Jomini left an engaging picture of Napoleon, his own logistician, sprawled on the floor, marking off with a pair of dividers on the map the marches of the several corps that were to converge on tomorrow's objective.

Despite the enormous influence of Jomini's writings on military thought during the long middle span of the 19th century, the word "logistics" gained only a limited currency in French (*la logistique*) and in English as a rather academic term used occasionally by the learned. German writers, including Jomini's great contemporary Karl von Clausewitz, used it not at all. Jomini's broad conception of the term was generally forgotten; in military parlance its meaning came to be restricted to supply, transportation and quartering of troops. In the 1880s Alfred T. Mahan introduced it into U.S. naval usage, and in the decade or so before World War I the navy's concern with the economic foundations of its expansion began to broaden the connotation of the word to include for the first time the processes of industrial mobilization and the functions of a wartime economy in supporting military operations, spheres of activity that in Jomini's day had seemed little related to the conduct of war.

2. Thorpe.—This broader conception of logistics was reflected in a little book published in 1917 by an obscure marine corps officer,

George Cyrus Thorpe, under the title *Pure Logistics*. Thorpe argued that the whole sphere of warmaking fell naturally into three subdivisions, strategy, tactics and logistics, and that since the first two by common understanding were concerned with the actual conduct of war by the fighting forces, the logical function of logistics was to provide all the means, human and material, for the conduct of war. It therefore embraced, Thorpe insisted, not merely the traditional functions of supply and transportation in the field, but also war finance, ship construction, munitions manufacture and other aspects of war economics.

Thorpe's conception of logistics did not win immediate acceptance, however, either in his own service or in the U.S. army, which also became involved in economic mobilization during World War I and was responsible during the 1920s and 1930s for planning for industrial mobilization in a future war. At the army's general services school at Ft. Leavenworth, Kan., logistics was defined as late as 1926 in traditional terms as "that part of the military art which embraces the details necessary to the movement and supply of troops in military operations."

3. World War II.—The word logistics came into sudden vogue in the U.S. during World War II at a time when paradoxically it had almost disappeared from military use in Europe. With wide usage came further confusion of meaning. The army service forces, comprising most of the army's supply and service agencies in the United States, defined logistics (largely in terms of its own functions) to include virtually all aspects of administration except training. During the war and after, in all the military services, the logistics label was attached indiscriminately to numerous staff and operating agencies exercising a variety of functions in the field of administration, and the army created several types of "logistical" field commands. Official definitions changed from year to year, and differed among the services. Army dictionaries belatedly recognized the term for the first time in 1944, in the traditional narrow sense; field service regulations did not follow suit until 1949. The navy, by contrast, before 1950 had embraced a conception of the term as broad as that propounded by Thorpe in 1917, even defining a separate sphere of "civil" logistics to cover industrial mobilization for war.

4. Postwar Definitions.—In 1948 the three unified military services agreed on an official definition that listed virtually all military activities dealing with the provision and administration of matériel, personnel and facilities. Two years later they added to the list training and welfare activities, and also the phrase "acquisition or furnishing of services." These additions seemed to give logistics a scope as broad as that of military administration itself, and marked the high point in the development of official interservice definitions of the word. After 1950 the trend was back toward narrower, more traditional conceptions. By the early 1960s logistics still included all aspects of transportation; the acquisition, construction and operation of military facilities; the entire range of matériel functions, from design and procurement through distribution and final disposition; and services (still unspecified). But of the once long list of personnel functions only hospitalization and evacuation remained.

Official definitions have scarcely affected usage, which remains stubbornly inconsistent and loose. In its narrowest application, logistics may mean simply military supply and transportation. At the other extreme, it may comprehend the provision in the broadest sense of men and matériel for military operations, including all the planning, administration and services therein involved, and reaching far back into the mobilization of the nation's economic resources for war. As one epigrammatic definition puts it, logistics is often likened to "the military element in the nation's economy and the economic element in its military operations."

Not all the specialists whose skills are thus blanketed consider themselves logisticians, however. To the radio operator or electronics technician, to the nuclear physicist or public information officer, to the personnel administrator, to the file clerk, even to the military engineer, logistics is likely to appear as a vague conglomeration of activities somewhere outside his own area of specialization. Most of the military specialists whose duties bring

them in contact with or even within sound of combat feel a strong aversion to the label of logistics because of its traditional noncombatant connotations. The word belongs, in fact, primarily to the vocabulary of the staff planner, for whom it serves as a convenient symbol to apply to whatever combination of noncombatant activities happens to be under consideration at the moment. Even in the language of staff planning, where "logistics" has become a familiar and overworked word, it is likely to be paired with a more precisely definable one, producing such locutions as "logistics and administration," or, inexplicably, "logistics and supply." Rarely in working military parlance does the occasion arise to use the word in its broadest sense. Where logistics stops and something else begins is, in fact, a question of serious concern only to the military theorist and the writer of official definitions.

II. ELEMENTS OF LOGISTICS

Viewed historically and analytically, logistics consists of four principal elements. Supply and transportation form the hard core, the primary functions by which armed forces are enabled to exist and to perform their essential tasks of moving and fighting. In addition, men and matériel alike depend for effective performance on a variety of services, such as repair and maintenance of weapons and equipment. The fourth element, closely related to services, is administration, considered in its general meaning as the function of organizing, co-ordinating and managing military activities.

1. Supply.—Supply is the function of providing the material needs of military forces. (It does not include the provision of men, which ordinarily is not considered an aspect of logistics.) In a narrow sense, supply refers only to distribution and the related function of storage. Broadly construed, it covers all stages in the life of an item of supply or equipment except its actual use or consumption; it includes design and development, manufacture, procurement, storage, distribution, salvage and final disposition. With these go such services as testing, maintenance, repair, packing and packaging, warehousing and veterinary service. Supply is also a planning-administrative process, paralleling the physical processes listed above and including such activities as contracting, pricing, scheduling, allocation and control of raw materials, components and facilities, industrial relations, conservation, inspection, stock control, administering of supply policies and procedures, requisitioning and the processing of requisitions. All these functions and processes fall into four broad phases: (1) production, in its nontechnical sense, including all steps in the creation of finished items of matériel; (2) procurement or acquisition of finished items by the military authorities from producing agencies; (3) distribution through the channels of supply; and (4) dominating the whole, the balancing of supply and demand, i.e., the determination of requirements and assets, and the scheduling of objectives in production and distribution.

While the character of military supply has varied with the changing technology of warfare, it has always had the basic aim of providing military forces the essential material means that enable them to live (food, water, clothing, shelter and medical supplies), to move (vehicles and transport animals, fuel and forage) and to fight (weapons, defensive armament and materials, other combat equipment and the expendables of fire or missile power). In all three categories are items such as clothing, vehicles and weapons that are used repeatedly, and therefore need only be replaced when lost, destroyed or worn out; and materials such as food, fuel and ammunition, that are expended or consumed, and therefore must be continuously or periodically resupplied. From these characteristics are derived the classifications of initial issue, replacement and resupply. Other more technical classifications are used in various countries and services. The U.S. army uses five main classifications: (1) subsistence and forage; (2) equipment and other items issued to organizations and individuals on the basis of allowance tables; (3) fuels; (4) equipment and materials of irregular issue; and (5) ammunition. The British army recognizes two broad classes: (1) supplies, which include all the expendables except ammunition; and (2) stores, which include ammunition and military hardware in general.

Food, Forage and Fuel.—Historically, food and forage made up most of the bulk and weight of supply requirements until the 20th century, when with mechanization and the growth of air power forage largely yielded to fuel. The demand for food is unremitting and undeferrable; since man himself, as a consumer of food, has changed little or not at all, it is the one constant of logistics. While a man can live without food for as long as five weeks, he becomes militarily useless long before that limit is reached; if deprived of water he succumbs in four or five days. A man's daily ration makes a small package—the U.S. army ration in World War II weighed only six pounds—but an army of 50,000 men may consume in one month as much as 4,000 tons of food.

Animals require much more: the standard grain and hay ration in the U.S. army in the 19th century was about 25 lb., and the daily forage for a corps of 10,000 cavalry weighed as much as the food for 50,000 men. Forage requirements tended, moreover, to be self-generating, since the animals needed to transport it also had to be fed. The number of animals accompanying armies varied widely. Napoleon described as an ideal, which he himself failed to attain, a supply train of no more than 500 wagons in an army of 40,000 men; with a corps of 7,000 cavalry, this would amount to about 10,000 animals. Northern armies in the American Civil War, whose transport was probably more lavish than the historical average, commonly numbered half as many animals as soldiers. A force of 50,000 men thus might require more than 300 tons of forage daily. This was more than twice the weight of gasoline that an equivalent force of three World War II infantry divisions, using motor vehicles exclusively, needed to operate for the same length of time. In the latter case, moreover, fuel requirements diminished markedly when an army was not moving, while the pre-mechanized force had to feed its animals whether moving or not. The expendables of movement in the 20th century, however, include fuel for rail and water transport as well as for motor vehicles and in addition the immense fuel requirements of modern air power. In World War II fuel and food made up more than half the total resupply and replacement needs of U.S. forces (not including fuel for transoceanic shipment), and almost 80% of their resupply of expendables. Food amounted to only 8% and 12%, respectively.

Ammunition and Equipment.—Before the advent of mechanization, complex weapons and massive firepower in the late 19th and 20th centuries, equipment replacement and ammunition resupply needs were relatively small. Missile power, in the ages before the invention of gunpowder, was limited by the difficulty of bringing large supplies of missiles to the battlefield. Much depended, in a protracted battle, on the speed with which spent arrows and javelins could be gathered up and turned against their original owners; the ancient slinger (effectively employed by Hannibal against the Romans) had an important advantage over the Bowman in using a projectile that was both more portable and more readily obtainable.

For five centuries after the invention of gunpowder the provision of ammunition was not a major logistical problem. Not until the use of field artillery on a large scale in the 18th century, and the development of quick-firing shoulder arms in the 19th, did ammunition begin to constitute a substantial proportion of resupply needs. As late as 1864, in the Atlanta campaign of the American Civil War, Gen. William T. Sherman's average daily ammunition requirements amounted to only one pound per man, as against three pounds for rations; Confederate forces, according to their chief of ordnance, expended on the average only half a cartridge per man per day.

The immense increase of firepower in the 20th century upset the historic ratios. In World War II the average ammunition requirements of U.S. forces overseas amounted to 14% of their total resupply and replacement needs, and 21% of their expendables. Earlier, in World War I, and again in the Korean War ammunition expenditures were higher. Replacement requirements also climbed in the 20th century, particularly in the lavishly equipped U.S. army, but only moderately as compared with the swelling tonnages of expendable supplies. Replacement of equipment and miscellaneous nonexpendables for U.S. forces in World War II absorbed only

13% of their total resupply and replacement requirements.

2. Transportation.—While strictly speaking a logistical service, transportation is usually considered an independent function of logistics because of the vital importance of movement (both of matériel and personnel) as a basic function of military forces. In the distribution phase of supply, transportation is, of course, the dominant element.

For 5,000 or 6,000 years of organized warfare, before the development of steam propulsion and the internal-combustion engine, armies depended for mobility on two sources of energy: the muscles of men and animals, and the force of the wind. On land they used men and animals to haul and to carry; on water they used oar-driven or sail-propelled vessels. Among these various modes the balance of advantage and disadvantage was often delicate, involving numerous variables. Movement by water was exposed to the hazards of storm and the vagaries of wind. Transports were vulnerable to attack by enemy warships; they were also limited in their carrying capacity, and expensive to hire or buy. Large overseas expeditions could be undertaken only by comparatively wealthy states, unless, as in the case of the Scandinavian rovers of the 8th and 9th centuries, the warriors were themselves mariners and seafaring was rooted in the economy. Only rarely was a force transported over water powerful enough to overcome a strong land-based foe—as the Persian invaders of Greece learned at Marathon in 490 B.C.—and its subsequent support was likely to be precarious.

On the other hand, armies have usually been able to move faster by water than by land. The natural roadway of the sea offers less friction and fewer obstacles to movement over its surface than even good roads, and military history contains few examples of good roads. In the 19th and 20th centuries construction of larger ships and the development of steam and other forms of propulsion made water travel largely independent of wind and weather, and made it possible to transport and sustain overseas larger forces than ever before. On land technological change was also under way. More and better roads were built, particularly in Europe and the United States, and the railroad, after the mid-19th century, enabled whole armies for the first time to move long distances more rapidly than a man could walk. Motor vehicles and more road building in the 20th century extended the conquest of rough terrain. The airplane, finally, freed military movement, for relatively small forces and limited amounts of matériel, from bondage to earth altogether. Yet the costs of mobility on land—in equipment, materials and energy—were high and military movements, except by small forces with little impedimenta, were still confined to narrow ribbons of rail and road constructed in advance. In large parts of the world these were largely lacking, and the technology of military movement was still primitive. Even in the mid-20th century, in short, movement by water retained the advantages inherent in its nonresistant medium.

On land, the soldier himself has always been the basic and indispensable burden carrier. As a matter of simple logistical economy, he represents large available carrying capacity at no extra cost. His equivalent, in an army of 50,000 men, would be 1,250 wagons drawn by 7,500 horses or mules; a difference of only five pounds in his individual load could add or subtract a requirement for 125 wagons and 750 animals. Since the days of the Roman legionary, the soldier's load has averaged, until recently, from 55 to 60 lb. Exceptions were few and conspicuous. Oliver Cromwell reduced the load of his New Model army to less than 40 lb. per man; the troops of Revolutionary France endured physical discomfort and developed foraging into a system in order to discard most of the personal impedimenta that had burdened the typical 18th century soldier; "Stonewall" Jackson's foot cavalry in the Civil War carried only musket, ammunition, a blanket or rubber sheet, a frying pan, a few personal necessities and on occasion three days' rations. The ratio between armament and vital needs in the soldier's load has varied widely, but the modern soldier has tended to relegate most of his food to vehicle transport, while carrying a heavier burden of weapons and ammunition. Recent research has discredited the traditional practice of using augmented training loads to develop endurance, and has emphasized the necessity of

reducing combat loads to a minimum, since fear and fatigue both drain muscular power. In most armies following World War II the soldier's load was drastically reduced, in the U.S. army to about 40 lb.

Before the age of steam, armies supplemented the soldier's carrying capacity both with additional manpower and with animal power. Each had its advantages, but the balance was fairly even. A team of six horses ate about as much as 40 or 50 men, but the men could carry more on their backs than the horses could haul, and considerably more than the horses could carry. Men could negotiate rougher terrain, and they required less care. On the other hand, when men were used as carriers their loads had to be distributed in small packages, and men proved less efficient than animals when teamed to haul heavy and bulky loads. (The one-man cart, an ancient means of conveyance, was used to good effect by the Koreans and Chinese in the Korean War and has a significant role in the logistics of the Chinese and Soviet armies.) The horse and mule, besides, have less strength and stamina, though more agility than the ox, which through the ages has been the primary beast of burden. As a mount for the warrior, making the most of its speed and height, the horse has served a more useful function, and one with logistical aspects as well, since mounted troops, whether they fought as infantry or cavalry, could move rapidly for short distances. With such rare exceptions, however, as the far-ranging cavalry armies of the Mongols in the 13th and 14th centuries, large cavalry forces were shackled, like infantry, to their slow-moving transport and to their bases. In general, animal transport has predominated in the military experience of the western world, where manpower has usually been scarce, while in the orient, where manpower is plentiful, men have been used even more than animals as military beasts of burden. Both forms of transportation continue to be used in the mid-20th century, wherever mechanical transport is insufficient or breaks down or runs out of fuel. In the Korean War the porter with his A-frame probably carried more tonnage than was carried by any other mode of land transport.

3. Services and Administration.—This is the shadowland where logistics merges into areas of military activity to which usage has generally not accorded the name. History and the activities themselves unfortunately recognize no line of functional demarcation that might suggest a distinction between logistical and non-logistical services and administration. Even the ancient distinction between combat-related and noncombatant activities has grown fuzzy in modern warfare, where so many specialized and unviolent skills (artillery fire direction, for example) may enter into the process of killing.

Services may be defined as activities designed to enable personnel or matériel to perform their appropriate functions more effectively; administration may be defined as the managing and ordering (as opposed to the actual performance) of a function or process—hence also the operation of an organization or installation. Since services themselves must be administered, both purposes are usually combined in the same activity.

The list of military services and administrative activities in modern warfare is long. Those associated with supply have already been mentioned. Transportation, itself a service, involves a subordinate service, stowage of freight, as well as the administering of troop and freight movements, control of traffic and documenting of shipments. Seven other major service-administrative areas can be discerned: (1) communications; (2) the construction, repair and maintenance of facilities (housing, depots, railroads, etc.), including operation of utilities and leasing and disposal of real property; (3) personnel services (medical, spiritual, legal, personal, informational, recreational) and administration (recruitment, induction, classification, assignment, maintenance of records, separation); (4) dissemination of public information; (5) finance and fiscal management; (6) military justice and discipline; and (7) military government. Administration itself, finally, has its own related service: the study and development of improved methods of management.

Even though not all these activities fall within the sphere of logistics by current usage and definitions, they may be referred

to collectively, for present purposes, as logistical services. Most of them are of recent origin, reflecting both the complex technology of modern warfare and the institutional complexity of modern society. Over the long run of military history, the logistical services considered necessary to keep soldiers, animals and equipment in fighting trim were generally of a rudimentary sort. From the earliest times, however, they posed a serious logistical problem. First, they added to armies and their lines of communications substantial, sometimes immense, numbers of people whose primary business was not to fight and who, if not properly organized, often impeded fighting. The soldier seldom possessed the technical skills required to perform any but the simplest logistical services; in some ages, as a member of the warrior class, he was even prohibited by social prerogative from performing them. The classic accompaniment of armies, consequently, has been its long train of non-combatants, often far outnumbering the fighting men.

Logistical services also added to the baggage of armies a growing burden of specialized equipment, tools and materials required for performance of the services. Services tended to generate more services: service equipment itself had to be serviced, sometimes by additional equipment manned by additional technicians and service personnel themselves required services. Logistical services thus meant more people to be fed, clothed and sheltered, and more people and baggage to be transported. This is the problem of what the British call the "administrative tail"; it is as old as military history.

III. POWER VERSUS MOVEMENT

The potential effectiveness of a military force lies in three attributes—power, mobility and range—*i.e.*, the ability to fight, to move freely and rapidly and to move far. Each depends on physical ingredients that must be provided and transported, and on logistical services that also place a burden on supply and transportation. Since logistical capabilities are almost always limited, power, mobility and range must compete for the available supply transportation and services. This competition over the ages has tended to focus on transportation, which for an army in the field almost invariably determined the amount and kind of supplies that could be made available, as well as the scale of services that could be provided, at the time and place needed. Given a fixed amount of transport, the amount of supplies and services it can deliver to a force in the field depends in the main on the distance it must travel in performing these functions. Three methods have been used, in combination and with varying emphasis: (1) self-containment, in which all that the force needs is carried along with it; (2) local supply, in which supplies and services are obtained from sources nearby or along the route of march; and (3) supply from bases, in which supplies are brought as needed from more distant sources.

1. Self-containment.—The idea of complete independence from external sources of supply has always exerted a powerful fascination. For many a commander plagued by supply troubles the hard-hitting, fast-moving, streamlined, self-contained "flying column" was a glittering ideal, which somehow never quite materialized. Self-containment in equipment, service personnel and even ammunition or missiles was the historical rule until the great expansion of fire power and of replacement requirements in the last century. Even in the 20th century, replacement of equipment and resupply of ammunition has normally been intermittent rather than continuous. Few military forces have been able to operate for long without frequent resupply of food, forage and fuel. The disintegration of the French army after its defeat at Blenheim in 1704, and of Napoleon's Grande Armée in the retreat from Moscow in 1812, resulted largely from exhaustion of accompanying supplies and inability to subsist on the countryside.

By its nature, self-containment is the least economical of all methods of supply. The available transportation is fully loaded only once at the beginning of the movement, and serves thereafter as a rolling warehouse, which is steadily depleted as the force eats into its food and fuel or forage. Thus only a fraction of the available capacity is put to use. Self-containment, in fact, offers few advantages other than that of moving by an unpromising, possibly

unguarded route, without delays or detours to replenish supplies. Hannibal gained this advantage when he crossed the Alps into northern Italy in 218 B.C., circumventing the Romans barring the easier coastal route—but in doing so he lost almost half his entire force. Gen. John Burgoyne's invasion of New York from Canada in 1777 with a virtually self-contained force bogged down in hostile country and ended in disaster at Saratoga. In general, self-containment requires the sacrifice of both fighting power and range of movement in a striving for mobility which may itself be defeated by the sheer weight of the expendable supplies that must be carried.

2. Local Supply.—Until modern times, supply from local sources (including captured stores) in the regions where armies operated was the commonest method of resupplying food and forage and of providing labour and other simple services. In fertile country, an army could usually meet at least a large part of its immense cumulative demand for the major expendables, at low cost in transportation and without sacrificing power or range. When efficiently organized to reduce delays and diversions, local supply even permitted a high degree of mobility. Normally, however, an army living off the country tended to straggle and to load itself down with loot. If it moved too slowly or was pinned down by the enemy, it might sweep the region bare and starve. In winter or in desert mountains local supply offered meager fare. And a hostile population, as Napoleon discovered in Russia and in Spain, could bring disaster to an army that had to scrounge for its food.

Yet, even when the troops could be fed by other means, the animals usually had to shift for themselves, for the burden of transporting forage any considerable distance could be prohibitive. Local supply of forage was in fact almost universal throughout the centuries before the advent of mechanized transport. Moreover, cattle driven along with an army could transform forage into food for the troops—a supply technique as ancient as biblical times and still common in the late 19th century. Unwieldy and slow-moving though it was, the accompanying herd had the great merit of transporting itself, and unlike the wagon train it dwindled as it was consumed. It was the forage requirement, far more than the problem of food supply, that served, as a general rule until recent times, to confine large-scale military operations to relatively settled, fertile regions and to the months of the growing seasons.

When mechanical transport replaced animals, one of the great continuities of military history was broken. Mechanized armies can operate in winter and desert areas as long as they have fuel. But when that is gone, they grind to a halt, for empty gasoline tanks cannot be replenished from fields and pastures. Mechanization closed the door to both self-containment and local supply as practicable logistical systems. Until power can be packaged in capsules or, like forage, gathered along the route of march, the door is likely to remain closed.

3. Supply From Bases.—The alternative to self-containment and local supply is continuous or periodic resupply and replacement from stores amassed in advance at accessible points. Each of these, or all together, constitute a supply base, a term also applied to a whole area embracing an army's sources of supply. In the past, supply from bases offered two main advantages over local supply: (1) bases were relatively secure from attack, and (2) they could be stocked with any desired quantity of war material. On the other hand, supply from bases involved, and still involves, three serious disadvantages. First, the movement of supplies over the routes, or lines of communications joining them to the army, may itself be interrupted or cut off by the enemy, and these supply lines, because of their length, are exceptionally difficult to defend. Second, an army shackled to its bases lacks flexibility and moves slowly, primarily because of the administrative friction and inertia involved in organizing a regular flow of supply from base to army. Finally, the transportation costs of maintaining the flow of supply even over short distances are heavy. These costs rise geometrically as the distance between army and base increases, since in order to deliver a load of supplies each vehicle must travel to the base and return, and additional food, forage and fuel must be carried for the personnel, animals and vehicles engaged in the movement. This geometrical increase in expendable requirements

for moving up supplies over a lengthening gap between a base and an advancing army progressively encroaches upon and eventually cancels out the capacity to deliver supplies to the army, regardless of the amount of transport used. With animal-drawn transport, the point of no return is reached very quickly. General Sherman, looking back over his experience in the American Civil War, concluded that an army thus supplied could not operate effectively more than 100 mi., or about five days' march from its base.

With mechanized transport, the theoretical operating radius is greatly extended. The U.S. army truck-and-trailer used in World War II, with $3\frac{1}{2}$ times the capacity of a Civil War-type army wagon, could travel as far on 100 lb. (13.3 gal.) of fuel as the horse- or mule-drawn wagon could travel on 750 lb. of forage. Thus, whereas in the Civil War as much as 75% of the transport used to sustain an army operating 100 mi. from its nearest base might have to be assigned to carry forage for the animals hauling the supplies, only 3% of the trucks used to supply a World War II army operating at the same range were needed to carry their own fuel. In both cases, the ultimate limit on the operating range of armies was theoretically absolute. In practice, armies using animal-drawn transport could evade the limitation by resorting to local sources for part of their forage, while for the modern mechanized army the ultimate limit was so great—perhaps 3,000 mi.—that it never became operative.

IV. LOGISTICAL SYSTEMS BEFORE 1850

The combination of local supply for food and forage and of self-containment in hardware and services appears often in ancient history as the logistical basis for operations by forces of moderate size. Three of these operations are familiar to every schoolboy—the 4,000-mi. march of Xenophon's Ten Thousand, the even longer campaign of Alexander the Great from Macedonia to the Indus and Hannibal's campaigns in Italy. The larger armies of ancient times—like that of Xerxes in the invasion of Greece in 480 B.C.—seem to have been supplied by depots and magazines along their routes of march. The Roman legion combined all three methods of supply into a marvelously flexible system. The legion's ability to march fast and far owed much to superb roads and to an efficiently organized supply train, which included mobile repair shops and a service corps of engineers, artificers, armourers and other technicians. Supplies were requisitioned from local authorities and stored in fortified depots; labour and animals were drafted as required. At need, the legion could carry in its train and on the backs of its soldiers up to 30 days' supply of provisions. In the First Punic War a Roman army marched an average of 16 mi. a day for four weeks.

One of the most efficient logistical systems ever known was that of the Mongol cavalry armies of the 13th century. It rested mainly on self-containment and local supply, supplemented by bases. In normal movements the Mongol armies divided into several corps and spread widely over the country, accompanied by trains of baggage carts, pack animals and herds of cattle. Routes and camp sites were carefully selected for accessibility to good grazing and food crops; food and forage were stored in advance along the routes of march. On entering enemy country, the army abandoned its baggage and herds, divided into widely separated columns and converged upon the unprepared foe at great speed from several directions. In one such approach march a Mongol army covered 180 mi. in three days. Commissariat, remount and transport services were carefully organized. The tough and seasoned Mongol warrior could subsist almost indefinitely on dried meat and curds, supplemented by occasional game; when in straits, he might drain a little blood from a vein in his mount's neck. The Mongol pony, bred on the steppe, could dig for forage through a light snow. Every man had a string of ponies; baggage was held to a minimum; equipment was standardized and light.

In the early 17th century Gustavus Adolphus of Sweden and Maurice of Nassau restored to European warfare a mobility not seen since the days of the Roman legion, mainly by careful organization of supply. The Swedish armies were based on pre-stocked magazines, but they also had compact supply trains with

well-organized services, a flexible tactical organization and light, standardized artillery. An important feature of Gustavian logistics was a system of orderly requisitioning that contrasted with the indiscriminate looting and devastation characteristic of the warfare of the day.

The formalized warfare of the 18th century was based on an elaborate and ritualistic system of logistics that sacrificed both range and mobility. This was the period of the rolling magazine, and of intricate systems of fortified depots and defended lines of communications. The growing size of armies, increasing use of artillery and greater attention to the creature comforts of a mercenary soldiery, all combined to place heavier burdens on transport. The retinues of baggage and servants accompanying higher officers assumed monumental proportions. At the same time, a widespread revulsion against the depredations and inhumanity of the religious wars in the preceding period brought sharp curbs on looting and other abuses; local supply took the form of carefully regulated requisitioning administered through municipal and provincial authorities under terms often defined by treaty. Since soldiers were expensive, there was a tendency to avoid battles (which, when they occurred, were bloody), and campaigns tended to degenerate into sluggish maneuvers with the primary aim of threatening or defending bases and lines of communications. War became an appendage of logistics in which, as Frederick the Great remarked, "the masterpiece of a successful general is to starve his enemy."

The era of the French Revolution and the Napoleonic domination of Europe (1789-1815) brought back both mobility and range to European military operations, along with an immense increase in the size of armies and the destructiveness of warfare. Logistics became simpler and in many respects cruder. French armies, operating on the principle that "war must support war," largely abandoned the rolling magazine, the elaborate system of supporting depots of the preceding period and even the requisition system. Baggage trains were pared down to the essential needs of fighting power and mobility. The soldier was often heavily burdened with weapons, ammunition and necessities formerly carried by the train; his greatcoat, for example, now served as his tent. Even so, he marched faster and farther (partly by virtue of an accelerated march cadence) than his opponents and predecessors. The system leaned heavily on the willingness of the patriotic citizen soldier (who in a few years became a veteran) to scrounge for himself, to do without and to suffer and die for lack of the rudiments of medical care. Napoleon himself avowedly counted on a brief campaign climaxed by a resounding victory to solve most of his logistical problems. The system, such as it was, tended to degenerate. Baggage trains grew larger; in the invasion of Russia in 1812 they were unable to keep up with the pace of advance and left the troops dependent upon a devastated countryside. In Spain too the logistics of local supply and self-containment broke down.

V. LOGISTICS IN THE INDUSTRIAL ERA

1. The Revolution in Warfare.—Between 1850 and 1950 the conditions and methods of logistics were transformed by a revolution in warfare more fundamental than any that had occurred in the preceding 6,000 years. The revolution had four facets: (1) the mobilization of mass armies; (2) a revolution in weapons that vastly increased firepower; (3) an economic revolution that provided the physical means needed to feed, munition and transport mass armies; and (4) a revolution in the techniques of management and organization, which enabled nations to mobilize their economic and human resources and to coordinate their use in a war effort often referred to, in the 20th century, as total.

These interrelated developments did not occur all at once. Armies of unprecedented size had appeared in the latter years of the Napoleonic Wars. But for almost a century after 1815, the world saw no similar mobilization of military manpower except in the American Civil War. Meanwhile, however, the rapid growth of populations (in Europe, from 188,000,000 in 1800 to more than 600,000,000 in the 1960s) was creating a virtually unlimited reservoir of manpower. By the latter part of the 19th century most

nations were building up large standing armies backed by even larger reserves, and the great 20th-century wars saw the mobilization by each major power of armies numbering many millions.

The revolution in weapons had also started earlier, with a series of inventions and scientific developments dating at least back to the latter part of the 18th century. Its impact upon armaments, in the form of weapons in widespread use, was not felt until about the middle of the 19th century. The rifled percussion musket, rifled and breech-loading artillery, heavy ordnance of very large calibres and steam-propelled and armoured warships were all coming into general use in the 1850s and 1860s. The details of the technological revolution, which proceeded with gathering momentum thereafter, cannot be summarized here. Each successive conflict brought forth a fresh crop of new and deadly weapons, but it remained for mass armies in the 20th-century world wars to realize the full potentiality for destruction that the new technology embodied.

By the mid-19th century the Industrial Revolution had already given a number of industrialized nations—especially Great Britain, France and the United States—the capacity to produce munitions, food, transport and many other items in quantities no commissary or quartermaster had ever dreamed of. In the American Civil War, the abundant munitions output of the still budding and only partially mobilized industrial economy of the Northern states dimly suggested the latent capabilities that might have been realized. But in general the wars of the 19th century hardly scratched the surface of the immense warmaking potential already in being. The generally limited character of all the conflicts between 1815 and 1914 can probably be attributed to the distribution of power and the nature of the international rivalries in this period. But even had these factors not tended to limit war objectives and to curb the mobilization of latent military power, it may be doubted whether managerial knowledge and techniques then in existence would have sufficed to carry out such a mobilization. It was, in fact, only in the crucible of World War I at the cost of colossal blunders and waste of effort that these techniques began to be learned.

Thus the full implications of the revolution in warfare were not revealed until the 20th century. Long before 1914, however, new instruments and techniques of logistics had begun to emerge.

2. Transportation and Communication.—The railroad, the steamship and the telegraph had a profound impact on logistical methods during the last half of the 19th century. From the Crimean War on, telegraphic communication was an indispensable tool of command, intelligence and operational co-ordination, particularly in controlling rail traffic. In the 20th century it yielded to more efficient forms of electronic communication—the telephone, radio, radar, television and telephotography.

Railroads spread rapidly over western and central Europe and the eastern United States between 1830 and 1860. They were used, mainly for troop movements, in the suppression of the central European revolutions of 1848-49, on a considerable scale in the Italian War of 1859, and extensively in the American Civil War where they also demonstrated their capacity for long hauls of bulky freight in sustaining the forward movement of armies. One of the revelations in this conflict was the speed with which torn up or blown up track could be repaired, and this remained true even after rail lines and junctions became prime targets for air bombardment in the 20th century.

In Europe, from 1859 on, the railroads shaped the war plans of all the general staffs, the central feature of which was the rapid mobilization and concentration of troops on a threatened frontier at the outbreak of war. In most countries railroad building was planned with this end in view. Germany's strategic rail network, the centre of Europe enabled it to exploit to the full the advantage of interior lines. In 1870 it was able to concentrate 550,000 troops, 150,000 horses and 6,000 pieces of artillery on the French border in 21 days, and its recognized efficiency in mobilizing troops influenced the war plans of all the European powers in 1914. In both world wars Germany's railroads enabled it to shift troops rapidly between the Russian and the western fronts.

In the 19th century, steam propulsion and iron ship construction

also introduced new logistical capabilities into warfare—the latter by breaking down earlier limitations on the size of seagoing ships, the former by freeing sea-borne transportation from the vagaries of the wind. Steamships moved troops and supplies in support of overseas operations in the Mexican War of 1846–48 and on a much larger scale in the Crimean War of 1854–56; river steamboats played an indispensable logistical role in the American Civil War.

The complement of the railroad was the powered vehicle that could travel on ordinary roads and even unprepared surfaces, within the operating zones of armies, forward of railhead. This was a 20th-century development, a combination of the internal-combustion engine, the pneumatic tire and the endless track. Motor transport was first used on a large scale in World War I, along with animal-drawn transport, and in World War II it became, next to the railroad, the dominant means of land movement. Another innovation was the pipeline, used to move water in the Palestine campaign of World War I, and extensively in World War II to move oil and gasoline to storage points close to the combat zones. More revolutionary was the development of air transportation. In World War II, units as large as a division were carried in one movement by air over and behind enemy lines, and resupplied by the same means. Cargo aircraft maintained an airlift for more than three years from bases in India across the Himalayas into China; during the last eight months of operation it averaged more than 50,000 tons per month—an airline of communications for a whole theatre of operations. But the fuel costs of such an operation were exorbitant. Despite the development of gigantic cargo aircraft, air transportation remained primarily a means of emergency movement when speed was an overriding consideration.

3. The Growth in Quantity.—The most conspicuous logistical phenomenon of the great 20th-century wars was the enormous quantity of matériel used and consumed. One cause was the growth of firepower, which was partly a matter of increased rapidity of fire of individual weapons, partly a higher ratio of weapons to men—both multiplied by the vast numbers of men now mobilized. A Civil War infantry division of 3,000 to 5,000 men had an artillery complement of up to 24 pieces; its World War II counterpart, numbering about 15,000 men, had 328 artillery pieces all capable of firing heavier projectiles far more rapidly. A World War II armoured division had an armament of nearly 1,000 pieces of artillery. Twentieth-century infantrymen, moreover, were armed with semiautomatic and automatic weapons instead of the single-shot muzzle-loaders used by most troops in the Civil War.

The upward curve of firepower was reflected in the immense amounts of ammunition required in large-scale operations. Artillery fire in the Franco-German War, and in the Russo-Japanese War, for example, showed a marked increase over that in the Civil War. But World War I unleashed a firepower whose existence had hardly been hinted at in the previous conflicts. In this holocaust British and French forces expended during one average month more than twice as much artillery ammunition as did the Union forces during the entire four years of the American Civil War, and in the seven-day battle of the Somme in 1916 British artillery fired about 4,000,000 rounds, or roughly 125 times as many as the Union artillery in the three-day battle of Gettysburg. In World War II the U.S. procured only about 4 times as many small arms as it had in the Civil War, but 43 times as much small-arms ammunition. The Confederacy fought through the four years of the Civil War on something like 5,000 or 6,000 tons of gunpowder; American factories in one average month during World War I turned out almost four times this quantity of smokeless powder. Again, in one year of World War II, 7,000,000 tons of steel went into the manufacture of tanks and trucks for the U.S. army, 4,000,000 tons into artillery ammunition, 1,000,000 tons into artillery and 1,500,000 tons into small arms—as contrasted with less than 1,000,000 tons of pig iron used by the entire economy of the Northern states during one year of the Civil War. To the ammunition expenditures in the 20th-century world wars were added, moreover, the immense tonnages of explosives used in air bombardment. It must be remembered, finally, that ammunition and explosives remained a relatively small item among the military

expendables; the weight of fuel and food was perhaps four times as great.

With growth in quantity went a parallel growth in the complexity of military equipment. The U.S. army in World War II used about 60 major types of artillery above .60 calibre, from the 20-mm. automatic aircraft cannon to the 16-in. coast artillery gun. For 20 different calibres of cannon there were about 270 types and sizes of shells. The list of military items procured for U.S. army ground forces added up to almost 900,000, and each end item contained many separate parts; fire control instruments for some anti-aircraft guns contained as many as 25,000 precision-made parts. To convert and expand a nation's peacetime industry to the production of such an arsenal posed staggering technical problems. Manufacturers of automobiles, refrigerators, soap, soft drinks, bed springs, toys, shirts and microscopes had to learn how to make guns, gun carriages, recoil mechanisms and ammunition.

4. The Determination of Requirements.—To design and manufacture a weapon in quantity took from 18 months to two years or more, the so-called lead time of logistical planning. The operation in which the weapon was used was rarely planned in detail more than six months in advance. From this circumstance was derived the central problem of logistical planning: how to predict, without operational plans, what would be needed to carry on a war, in time to produce and make the matériel available when needed. In World War II the U.S. army developed elaborate administrative processes for accomplishing this feat, involving hundreds of statisticians and technical experts, electrical computing machinery and an army of clerical personnel.

Fundamentally the method was simple. Instead of "guestimating" the needs of all possible future operations not yet planned or conceived, requirements were calculated item by item for the army as a whole, on the basis of general expectations as to its composition, rate of expansion and overseas deployment, and the areas where it would operate. Requirements were grouped under the following headings: (1) initial equipment for each soldier and troop unit that the army expected to mobilize; (2) replacement equipment to cover expected losses in use and in combat, as indicated by analysis of past experience; (3) consumption and expenditure requirements for expendable supplies, also based on past experience; and (4) distribution requirements for both equipment and supplies needed to "fill the pipeline" in the army's worldwide system of supply (i.e., quantities stocked in depots, in transit, and lost in transit), and thus ensure ready availability when and where needed. Reserves were also provided to cover unforeseen needs, and specific bills of requirements added for planned operations and for certain projects (e.g., the reconstruction of a port) that could be foreseen. In general, the aim of the system was to provide a diversified fund of war material of all kinds, from which, it was hoped, specific needs could be met as they arose. The British in World War II used a somewhat different method which emphasized the calculation of requirements for forces in each theatre of operation.

5. The System of Staged Resupply.—Long before mechanization relegated local supply to a minor role in the support of modern armies, growing supply requirements had made armies dependent on more or less continuous resupply from bases. The *étappen* system of the Prussian army in 1866 was essentially a modification of the rolling magazine of the 18th century. Behind each army corps trailed a series of supply trains, shuttling continuously between the advancing troops and the nearest magazines in the rear. The magazines were repeatedly moved forward to keep within one or two days' march of the advance, and were in turn replenished by a lengthening chain of magazines extending back as far as the railhead. Only a small train accompanied the troops, carrying a basic load of ammunition, rations and baggage; each soldier carried three days' emergency rations. The system was geared to a steady, slow advance on a rigid schedule and a predetermined route, and the individual soldier was still heavily laden. Yet no alternative method seemed possible, since in 1866 and again in 1870–71 Prussian forces were able to obtain no more than a third of their supplies locally.

Staged, continuous resupply became the basic logistical sys-

tem for all armies in the industrial era, and for large, well-equipped forces sustained reliance on self-containment and local supply virtually disappeared. Accompanying loads were limited mainly to fighting equipment and a small reserve of fuel and ammunition, and soldiers carried a day or two of emergency rations. The administrative tail of magazines and shuttling transport stretching far back to the army's sources of supply became a regular feature of modern land warfare. In World War II, supplies moving to U.S. armies overseas normally passed through seven or eight major stages, besides numerous intervening ones: from a depot in the U.S. to a port of embarkation, to an overseas port, to a rear-area depot and perhaps to an intermediate or advanced depot, to a regulating station, to an army-area supply point, to a division or regimental supply point and finally to the troops.

Under this system, even though it was frequently described as a pipeline, supplies never flowed continuously from ultimate source to consumer. The object was to stock reserves of material as far forward as safe and practicable, making possible regular supply of food and fuel, and immediate provision of ammunition, replacement equipment and services when needed. Before any major operation, large reserves had to be accumulated close behind the front; the build-up of U.S. war matériel in the British Isles preceding the Normandy invasion of 1944 went on continuously over a period of two years, and involved the shipment of 16,000,000 tons of cargo across the Atlantic from the United States. In essence, the system strove to convert supply from bases into an approximation of local supply, by moving the bases close to the troops.

Behind the armies, in the continental European theatre in World War II, spread the rear-area administrative zone, a vast complex of depots, traffic regulating points, railway marshaling yards, troop cantonments and rest areas, repair shops, artillery and tank parks, oil and gasoline storage tanks, airfields and headquarters—through which ran the lines of supply stretching back to ultimate sources. In the Pacific, the administrative zone covered vast reaches of water, and most of the bases were on islands. Communication and movement in this theatre depended largely on shipping, supplemented by aircraft, and one of the major logistical problems was moving forward bases and reserves as the fighting forces advanced. Late in the war, supply ships often sailed all the way from the U.S. west coast, bypassing intermediate bases, to forward areas where they were held as floating warehouses until their cargoes were exhausted.

The system of staged resupply gave modern armies considerable range of movement and sustained offensive power, but it crippled their mobility. The natural habitat of the system was the creeping or sealed front of World War I, though many offensives on the western front bogged down, after gaining a few miles, through failure of supplies to keep up with the advance. World War II brought back maneuver and rapid movement, but mobile forces remained tied to their bases; they could move only so far and so long as their supplies could be carried to them. Both the capabilities and limitations of the system were dramatically demonstrated when the U.S. 3rd army plunged across France in the summer of 1944, only to halt after four weeks because the racing armoured spearheads had outrun the capacity of their methodically shuttling transport. Even though used on a lavish scale, motor vehicles could not keep them supplied with the quantities of fuel required.

One of the striking lessons of World War II, often obscured by the tactical achievements of air power and mechanized armour, was the great power that modern logistics gave to the defense. In 1943 and 1944 the ratio of superiority enjoyed by Germany's enemies in output of combat munitions was about $2\frac{1}{2}$ to 1; the whole apparatus of Germany's war economy was subjected to relentless attack from the air, and had in addition to make good the enormous losses of material resulting from a succession of military defeats. Yet Germany was able, for about two years, to hold its own, primarily because its waning logistical strength could be concentrated on sustaining the firepower of forces that were stationary or were retiring slowly toward their bases, instead of on the immensely expensive effort required to support a rapid forward movement.

6. Logistical Specialization.—For many centuries the soldier was a fighting man and nothing else; he depended on civilians to provide the services that enabled him to live, move and fight. Even the more technical combat and combat-related skills, such as fortification, siegecraft and the service of artillery, were traditionally civilian. After the mid-19th century, with the rather sudden growth in the technical complexity of warfare, the military profession faced the problem of assimilating a growing number and variety of specialized noncombatant skills. Many of the uniformed logistical services date from this period; examples are the British army's transport corps (later Royal army service corps), hospital corps, and ordnance corps and the U.S. army's signal corps. In the American Civil War the Union army formed a railway construction corps, largely civilian in composition and operation but under military control. Prussia a little later created a railway section in the great general staff and a combined military-civilian organization for controlling and operating the railroads in time of war.

Not until the 20th century, however, did organized military units performing specialized logistical services begin to appear in large numbers in the field. By the end of World War II, what was called "service support" comprised about 45% of the total strength of the U.S. army. Only three out of every ten soldiers had combat functions, and even within the ranks of a combat division, one man out of four fell into the noncombatant category. Even so the specialized services that the military profession succeeded in assimilating were only a small fraction of those on which the combat soldier depended. Throughout the vast administrative zones behind combat areas and in the national base, armies of civilian workers and specialists manned depots, arsenals, factories, communications centres, ports and the other apparatus of a modern society at war. Military establishments employed a growing number of civilian administrators, scientists, management and public relations experts and other specialists. Within the profession itself, the actual incorporation of specialized skills was limited, in the main, to those directly related (or exposed) to combat, such as the operating and servicing of military equipment, though even here the profession had no monopoly. Soldiers also served as administrators and supervisors over civilian specialists with whose skills they had only a nodding acquaintance. On the whole the fighting man at mid-20th century belonged to a shrinking minority in a profession made up largely of administrators and noncombatant specialists.

VI. LOGISTICS IN THE NUCLEAR AGE

The dropping of the first atomic bombs in Aug. 1945 and the subsequent emergence of nuclear and thermonuclear weapons systems employing long-range missiles as well as manned aircraft inaugurated a new era in warfare, which promised to demand radical changes in logistics and logistical systems as well. But the new weapons were not immediately used in war; the limited conflicts of the 1950s employed, in the main, the weapons and logistical methods of World War II.

1. Korean War.—The major conflict in this period, the war in Korea (1950–53), was reminiscent in many ways of the positional warfare in Italy in World War II. For U.S. forces, the near-disastrous retreat to the Pusan perimeter at the outset of the war recalled the tragedy of Bataan early in 1942. In many other respects, the war seemed an extension of World War II—even to the stocks of munitions left over from that conflict without which the UN operations of the first year could hardly have been supported. Late in the war, U.S. forces began to use new model trucks, but they represented no new departure in design. Weapons were also mostly World War II models, in some cases improved versions.

UN forces had an excellent base in nearby Japan, whose factories made a major contribution by rebuilding U.S. World War II matériel. Both Japan and South Korea's major port of entry, Pusan, were free from Communist air attack throughout the war. Chinese bases north of the Yalu enjoyed a similar immunity from UN air raids. This curious circumstance greatly simplified the supply problems of UN forces, enabling them to

funnel through Pusan supply tonnages comparable to those handled by the largest ports in World War II, and to concentrate depots and other installations in the Pusan area to a degree that would have been suicidal without complete air superiority.

The expenditure of artillery ammunition by UN forces at times soared above the highest levels attained in World War II, and the available supply often fell dangerously low. Output of ammunition in the U.S. was meagre, because of the long lead time needed to reach quantity production and of the expectation that the war would not last long. Actual shortages on the firing line were primarily a result of inadequate transportation facilities in Korea. UN forces also suffered at the beginning of the winter of 1950-51 for lack of winter clothing which had not been moved forward soon enough. The numbers of service troops never seemed to be adequate, although they were considerably greater than was normal in World War II, and were supplemented by large numbers of Korean labourers—more than 150,000 in the fall of 1951. Korean porters made a major contribution to the UN transport service in rugged terrain which trucks could not negotiate.

Communist supply lines, though heavily bombarded by UN air forces, functioned remarkably well; troops and supplies were moved by night, local labour and transportation were used extensively and the Chinese soldier proved, as he had often done during World War II, that he could endure an incredible amount of privation, subsist on very little food and still fight well. The Communist logistical system, technically primitive, enabled the Communist forces to mount heavy offensives, but they could not be sustained for more than three or four days. On the UN side, the most brilliant logistical exploit was the "amphibious operation in reverse" by which the X corps was evacuated from Hungnam in Dec. 1950. In a period of two weeks, under constant enemy attacks, about 105,000 troops, 98,000 Korean civilians, 17,500 vehicles and 350,000 tons of cargo were loaded in 193 vessels.

By World War II standards, the Korean War was a limited conflict (except for the two Korean belligerents, on whose soil it was fought). It involved only a partial, or "creeping" economic mobilization in the U.S., the major UN participant, and a modest mobilization of reserve manpower. Yet this was no small war. During the three years that it lasted, about 37,200,000 measurement tons of cargo were poured into the South Korean ports, or more than three-fourths of the amount shipped to U.S. army forces in all the Pacific theatres from Dec. 1941 to Aug. 1945. And the combined UN forces reached a peak strength of almost 1,000,000 men, of whom more than a third consisted of U.S. and other non-Korean contingents. Communist forces were considerably larger. (See also KOREAN WAR.)

2. Management.—Logisticians were much concerned in the post-World War II period with improvements in management aimed at greater economy and efficiency. This was no new trend, for World War II had seen a major effort, especially in the service forces and air forces of the U.S. army, to bring order and reasonable economy into operations which, because of their unprecedented magnitude, tended to breed waste and duplication. In the postwar years the slashing of military appropriations, the increasing cost of military hardware in a period of rapid technological change and growing international tensions all combined to put heavy pressure on the armed services to squeeze more military strength from the defense dollar—to get, as the saying went, "more bang for a buck."

To a considerable extent, the methods adopted to improve management in logistics were those used in the business world, though in many cases they had actually developed, and in some cases had their origin, in the military establishments. Civilian management firms, hired to survey these establishments, gave a strong impetus to the organization of logistical activities along "functional" lines, as opposed to the traditional organization by commodity groups with headquarters of the general-staff type—though the attempt to do so was successfully resisted in many quarters. Under the unified military establishment in the U.S., all activities were grouped into major and subsidiary "programs," with orderly schedules of objectives which were continuously matched against performance. Unification also spurred efforts to break down the

uneconomical compartmentation of logistical activities under each armed service. Large groups of related functions (e.g., military transportation by land, water or air, or procurement of subsistence, clothing or medical supplies) were placed under the control of one of the armed services or a single interservice agency. In overseas commands certain logistical activities were also "unified" for all three services.

In the technology of logistical administration, an innovation of revolutionary implications was the introduction of completely automatic electronic data processing machinery. Applied to such large-scale operations as the processing of supply requisitions and control of inventories, this development held promise of reducing to small proportions the factor of time in many areas of logistical activity, of centralizing control to an unprecedented degree and of slashing administrative manpower requirements.

Another significant development was "operations research" or "operations evaluation," a form of scientific study and investigation which used advanced mathematical techniques in the analysis of repetitive operations, particularly those involving the use and performance of military hardware, with a view to developing more efficient methods and procedures.

Operations research was applied to many areas of military and business operations, but proved especially productive in the analysis of logistical activities.

3. Logistics in Nuclear War.—For logisticians, however, the fundamental dilemma posed by the "quantum jump" in weapons technology after World War II was the absence of any comparable development in the apparatus or methodology of logistics. No technical innovation perfected and applied during this period, in transportation, supply or administration had an impact upon the conduct of war remotely comparable to that produced in the 19th and early 20th centuries by the railroad, the telegraph, the internal combustion engine or mass production. On the other hand, the new weapons, with their immense destructiveness and range, threatened to sweep away every vestige of the logistics developed to meet the demands of the industrial era. None of the elaborate apparatus of rear-area administration, lines of communications or even sources of supply required in the two world wars of the 20th century seemed likely to survive the firepower that could now be brought to bear against it, and no effective defense against this firepower had yet appeared.

The problem was, indeed, under attack from many angles. New logistical doctrine stressed dispersion, and much study went into the determination of how small a concentration of personnel or structures constituted a "profitable target." In the future war, the communications zone would be wide and deep; installations would be small, widely dispersed, duplicated on a large scale to avoid irretrievable loss, and, as far as possible mobile; depot stocks would be mixed instead of specialized; automatic data processing machinery would permit rapid supply action by remote control; a variety of small, mobile cargo carriers would be available, combining the functions of storage and movement, and capable of traveling on any terrain; cargo would also be carried by helicopter and aircraft that could use water runways; "roll-on-roll-off" sea-going and submersible carriers would discharge their cargoes rapidly on small beaches and immediately put out to sea; all movements of troops and cargo would be spread among numerous alternate routes. Combat units, small, mobile, lean, stripped down to the bare essentials of equipment and services, would resupply themselves from small dispersed magazines, or be resupplied by aircraft and fast-moving supply columns.

Yet all this, by the early 1960s, was still hardly more than a planner's vision. At best, it held promise of reducing to some degree the inherent vulnerability of the surface-bound installations and transport on which military forces in the foreseeable future were likely to depend for most of their logistical support. Dispersion and duplication were enemies of economy and efficiency, and the more advanced new means of movement, storage and handling were expensive, intricate and difficult to produce in quantity. The net effect could only be to increase the costs of logistical support and to diminish the yield in delivered supplies and services.

The central problem of logistics in the nuclear era, as before, was one of weight and bulk—the historic barriers to mobility and range, and the primary causes of vulnerability to the new firepower. With substantial reductions in weight and bulk of impedimenta and supplies, the pace of supply movements would quicken, armies could thin out the density of their rear-area installations and lines of communications, and the self-contained, hard-hitting “flying column” might return to warfare. Some promise of a real breakthrough in this area was offered by the application of atomic energy to transportation. Atomic-powered vehicles, whether on land, on the sea, under water or in the air, would consume virtually no fuel, and in World War II fuel had accounted for from two-thirds to three-fourths of the weight of all supply requirements. The first atomic-powered submarines and surface vessels appeared in the 1950s, and nuclear submarines, by the 1960s, had become a regular component of the U.S. navy. A further reduction of transportation requirements was inherent, too, in the new weapons themselves, which replaced many times their own weight and bulk in the older types of explosives and delivery instruments.

The growing range of firepower, moreover, involved a corresponding diminution of the distances over which the ingredients of firepower and logistical support had to be transported. Intercontinental missiles and bombers, based in a nation's home territory, theoretically could eliminate altogether the need for advanced air and missile bases, along with the defending forces, lines of communications and administrative establishments that supported them. By the 1960s all the major powers had to reckon with the possibility that the sources of logistical support might, in any case, be wiped out, and lines of communication rendered inoperable by the initial strikes and counterstrikes of an all-out nuclear war. In such a case, the ensuing “broken-backed” conflict, if hostilities continued at all, would have to be waged by surviving forces in being with whatever weapons, supplies and transport remained. It could readily be envisaged that warfare under these circumstances might eventually revert to more primitive pre-industrial forms.

Logistical planners still had to reckon, however, with the probability of limited wars, with or without nuclear weapons, and with such present realities as limited budgets and interservice competition for funds and priorities. Development of new tools for logistics lagged behind the development of new weapons. The motor vehicles, ships, railroads and air transports in general use by the 1960s were not significantly different from those used in World War II. Despite plans for dispersion, mobility and automated supply procedures, military forces remained dependent on the system of staged resupply from bases, elaborate service support and ponderous administration that had characterized the logistics of the industrial era.

LOGOGRAM AND SYLLABARY. Under this heading are included systems of writing that utilize logograms, or signs for words, and syllabograms, or signs for the syllabic components of words. (For systems of writing that utilize letters or signs for the smallest elements of language, namely phonemes, see ALPHABET.)

The systems of writing that utilize logograms and syllabograms may be divided into two classes: (1) logosyllabic writing, which utilizes in about equal measure signs both for words and for syl-

lables; and (2) the syllabic writing, which either contains only signs for syllables or utilizes syllabic signs more than logographic signs.

Logosyllabic Systems.—This term includes full systems of writing, which represent actual units of language, such as words and syllables. They are to be distinguished sharply from primitive systems, which express vaguely defined ideas or meanings. The latter are called pictographic, ideographic or semasiographic systems and are forerunners of writing. (See WRITING; PICTOGRAPHY.)

Full systems of writing originated in the vast mass of land extending from the eastern shores of the Mediterranean sea to the western Pacific. In this large area seven original systems of writing developed, all of which could claim independent origin: (1) Sumerian in Mesopotamia, 3100 B.C.—A.D. 50; (2) proto-Elamite in Elam, 3000-2200 B.C.; (3) proto-Indic in the Indus valley, c. 2200 B.C.; (4) Chinese in China, 1300 B.C.—present; (5) Egyptian in Egypt, 3000 B.C.—A.D. 400; (6) Cretan in Crete and Greece, 2000-1200 B.C.; and (7) Hittite in Anatolia and Syria. 1500-700 B.C.

New systems of writing come to light from time to time through the efforts of excavators. The proto-Armenian inscriptions, which have been discovered in great numbers in Armenia, are too little known to warrant their addition to the list. The undeciphered Phaistos and Byblos writings are most likely syllabic and thus fall under the classification of syllabic writings. The mysterious Easter Island inscriptions, on which much effort has been spent by many imaginative minds, probably represent pictorial concoctions for magical purposes. Finally, the Amerindian systems of the Mayas and the Aztecs do not represent full writing, since even in their most advanced stages they never attained the level of development characteristic of even the earliest phases of the seven systems.

Sumerian System.—The home of cuneiform writing was in Mesopotamia, in the basin of the Tigris and Euphrates rivers. The term cuneiform means literally “wedge form,” from Latin *cuneus*, “wedge,” plus *forma*, “form,” and owes its origin to the wedgelike appearance of the little strokes. The decipherment of cuneiform was initiated in the first half of the 19th century by Georg Friedrich Grotefend and Sir Henry Creswicke Rawlinson; by the end of the century it was possible to read with relative ease the various forms of cuneiform in which many languages of the ancient near east were written. Chief among these were Sumerian, spoken in southern Mesopotamia by a people of disputed ethnic and linguistic affiliation, and Akkadian, a Semitic language spoken in all of Mesopotamia, which included two main dialects, Babylonian and Assyrian. Toward the end of the 3rd millennium B.C. the Sumerian language died out, giving way to Akkadian.

Throughout its history the material par excellence of Mesopotamian writing was clay. As the rounded forms of pictures could not easily be incised on clay with a stylus, the signs acquired an angular form consisting of a few separate strokes of the stylus. The natural pressure of the stylus on one of its corners produced the appearance of wedges. Cuneiform was later used on other materials, such as stone and metal.

The Mesopotamian cuneiform system included about 600 logograms, out of which about 100-150 signs, depending on time and area, were used syllabically. The normal Mesopotamian syllabic writing contained signs of the type *ta*, *tu*, *tam*, *tum*. At no time did any of the Mesopotamian syllabaries contain signs for all the possible syllables in the languages for which they were used. The attempt to express linguistic forms with the fewest possible signs resulted in various economizing measures. No Mesopotamian system distinguished between voiced, voiceless and emphatic consonants in the case of signs ending in a consonant. Thus, the sign IG had the value *ig*, *ik* and *iq*, just as the sign TAG might have stood for *tag*, *tak* and *taq*. In addition, some older systems, such as Old Akkadian and Old Assyrian, did not even distinguish the quality of the consonant in signs beginning with a consonant. Thus, in these systems the sign GA had the value of *ga*, *ka* and *qa*. In all cuneiform systems many signs ending in *i* might stand also for those ending in *e*, as in the sign LI with the values *li* and *le*.

Syllables which were not represented by a sign in the syllabary might be represented by signs with similar consonants, as, for instance, in expressing the syllable *rin* with the sign which had a normal value *rim*. When there were no signs with similar consonants, a syllable was written in Sumerian in a way not paralleled in any other syllabic system; the syllable *ral*, for which no separate sign existed, was written as *ra-al*, while in other known syllabic systems this syllable would be written *ra-l(a)*, *ra-l(e)* or the like. (See also SUMERIAN LANGUAGE; AKKADIAN LANGUAGE.)

Egyptian System.—The name of the hieroglyphic writing of the Egyptians is derived from the Greek *hieroglyphika grammata* and owes its origin to the belief that it was used chiefly by the Egyptians for sacred purposes (*hieros*, "sacred," *glyphein*, "to incise"). By 1822 the hieroglyphic writing was successfully deciphered by the Frenchman Jean François Champollion, chiefly on the basis of comparison with the Greek inscription on the Rosetta stone (*q.v.*). The hieroglyphic form of writing, used chiefly for public display purposes, was not the writing of everyday practical life. For such purposes the Egyptians developed two forms of cursive writing, first the hieratic and then the demotic. The Egyptian system consisted of about 700 signs, of which about 100 were used syllabically. The syllabary consisted of about 24 signs, each with an initial consonant plus any vowel, such as the sign *m*^o with the values *m*^a, *m*ⁱ, *m*^e, *m*^u and *m*^(u), and of about 80 signs, each with two consonants plus any vowel(s), such as the sign *t^am*^a with the values *t^am*^a, *t^am*ⁱ, *t^am*^e, *t^am*^u, *t^am*ⁱ, *t^am*^e, *t^am*^(u), *t^am*^(e), *t^a(u)*^a, etc. This characterization of the Egyptian non-logographic writing as consisting of signs expressing one or two consonants plus any vowel is in disagreement with the views of many Egyptologists, who say it is simply consonantal or even alphabetic. (See I. J. Gelb, *A Study of Writing*, pp. 76-81 [1952].) (See EGYPTIAN LANGUAGE; HIEROGLYPHS.)

Hittite System.—The decipherment of the Hittite hieroglyphic writing was achieved in the 1930s through the combined efforts of several scholars. Knowledge of Hittite has not reached the level of Sumerian or Egyptian. The term hieroglyphic was taken over from Egyptian writing, and it simply implies that Hittite writing, like Egyptian, was picture writing; it does not imply that the Hittite hieroglyphic system was borrowed from the Egyptian hieroglyphic or that it was in any way related to it. Hittite hieroglyphic writing was in use from about 1500 to 700 B.C. in a large area extending from central Anatolia to northern Syria. Its language was related to, but by no means identical with, cuneiform Hittite, a language preserved in the cuneiform writing borrowed from Mesopotamia. Both of these languages and writings were used simultaneously in the Hittite empire, but while cuneiform Hittite was limited to the area around Bogazköy, the capital of the empire, and died out soon after 1200 B.C., hieroglyphic Hittite was used throughout the empire and continued as a living tongue up to about 700 B.C. Hittite writing consisted of about 450 signs, of which about 60 were used syllabically. The syllabic signs were of the type *ta*, *ti*, *te*, *tu*, each representing a syllable beginning with a consonant and ending in a different vowel. (See HITTITES.)

Chinese System.—Of the four main systems of writing, Chinese is the only one which did not have to be deciphered in modern times, because knowledge of it was passed from generation to generation. Chinese writing made its appearance about the middle of the 2nd millennium B.C., during the Shang dynasty, as a fully developed phonetic system. In its outer form the writing has changed greatly during its long history, but the inner characteristics of the oldest inscriptions hardly differ from those of recent times. The oldest Chinese inscriptions are the oracle texts on animal bones and tortoise shells, and some short texts on bronze vessels, weapons, pottery and jade. The signs in the Shang period were limited in number, no more than about 2,500, and in the majority of them the pictorial character is still clearly recognizable. But the signs developed a linear form, and in later writings it is impossible to recognize the pictures they originally represented.

Chinese writing does not have a full syllabary comparable to the syllabaries in the other three (major) systems. As the words of the Chinese language are regularly expressed by word signs, it is only in writing foreign words and names that the necessity

arose to use word signs in a syllabic function. Thus, "Jesus" is written as *Yeh-su*, "English" as *Ying-chi-li*, "French" as *Fa-lan-hsi*, "telephone" as *te-li-feng*. There are no set word signs for certain syllables, as there are in the near eastern systems; for example, "Jesus" might also be written *Ya-su*; "telephone," *te-lu-fung*. The characteristic tendency of Chinese toward abbreviation may be noted in the use of *Ying* for "English" (besides *Ying-kuo-jen* for "Englishman," that is, "English-country-man"), *Fa* for "French" (besides *Fa-kuo-jen*) or *Lo* for "Roosevelt" (besides *Lo-ssu-fu*). Frequently, words spelled out syllabically acquired a logographic spelling; for example, the above-mentioned *te-li-feng*, "telephone," is now usually written as *tien-hua*, "electricity talks." Chinese writing is said to consist of about 50,000 signs, of which an unspecified number are used in a syllabic function. This extraordinary development of Chinese logography constitutes a unique phenomenon in the history of writing. (See CHINESE LANGUAGE.)

Proto-Elamite, Proto-Indic and Cretan Systems.—All these systems are either completely or largely undeciphered. The proto-Elamite writing first appeared at Susa, the capital of ancient Elam, and can be dated roughly to the so-called Jemdet-Nasr period after 3000 B.C. The earliest examples are found on several hundred clay tablets, perhaps business records. Not even one of the several hundred signs can be read certainly. Some number signs and the existence of a decimal system have been determined with some assurance. A more developed form of proto-Elamite writing, also undeciphered, occurs on about a dozen stone inscriptions from the Old Akkadian period around 2200 B.C. The later type of writing consisted of a very limited number of signs (only 55 have been discovered) differing greatly in form from those of the previous period.

Seals with peculiar signs, which have aroused intense interest throughout the world, have been found sporadically during the 20th century at various sites in the Indus valley. In 1924 the archaeological department of the government of India undertook the first systematic excavation of the ancient sites today called Harappa and Mohenjo-Daro, and a considerable number of texts were discovered. More inscriptional material of the same nature was uncovered at Chanhudaro. At these sites cultures of great antiquity were unearthed, about which, strangely enough, Indic tradition says nothing. The still undeciphered writing consists of about 250 signs found on short seal inscriptions, pottery and copper tablets. The relative chronology of this proto-Indic writing was established by comparative stratigraphy with the help of Mesopotamian finds. The writing made its appearance in the second half of the 3rd millennium B.C. and, after a few centuries, disappeared as suddenly as it had appeared.

The origin and development of the Cretan writing are best illustrated by the epigraphic finds made at the beginning of the 20th century by Sir Arthur Evans at Knossos, in Crete. Other sites in Crete (Mallia, Hagia Triada) and in Greece (Mycenae, Orchomenus, Pylos, Thebes, Tiryns), as well as in the Aegean islands, have yielded epigraphic material that supplements the knowledge derived from the Knossos material.

The two major classes of Cretan writing are the Hieroglyphic and Linear. The undeciphered Hieroglyphic A and B are probably of the standard logosyllabic type. Linear B is predominantly syllabic, as is the still undeciphered Linear A system. (See MINOAN LINEAR SCRIPTS; INDUS CIVILIZATION.)

Syllabic Systems.—Four syllabic systems developed from the logosyllabic systems discussed above: the cuneiform syllabaries from the Mesopotamian cuneiform; the West Semitic syllabaries from the Egyptian; the Aegean syllabaries from the Cretan; and the Japanese syllabary from the Chinese.

Cuneiform Syllabaries.—Mainly during the 2nd millennium B.C. the cuneiform writing of the Sumerians and Akkadians was borrowed by many peoples surrounding Mesopotamia, such as the Elamites of Iran, the Hurrians of northern Mesopotamia and Syria, the Hittites of Anatolia and the Urartaeans of Armenia. Only the Hittites took over the Mesopotamian logosyllabic system in approximately the form it had at its original home. All others simplified their cuneiform writings considerably by limiting their

systems to syllabic signs plus a small number of logograms for the most common nouns.

West Semitic Syllabaries.—In contrast to the East Semitic group of languages, represented only by Akkadian, all other Semitic languages, such as Phoenician, Hebrew, Aramaic, Arabic and Ethiopic, belong to the West Semitic group. This linguistic grouping is paralleled by a grouping based on graphic considerations. The Akkadians used cuneiform writing, while all other Semites used writing that was first developed on the Egyptian model in the middle of the 2nd millennium B.C. in the Syro-Palestinian area and reached its climax about 1000 B.C. in the Phoenician writing of Byblos, from which it spread to the surrounding West Semitic peoples.

All the West Semitic writings used a limited number of syllabic signs, 22 to 30, each of which expressed an initial consonant plus an inherent but unindicated vowel. With the development of separate vocalic signs in the first centuries A.D., the originally syllabic signs of the West Semitic writings became alphabetic, and the West Semitic writings became alphabets. (See also SEMITIC LANGUAGES.)

Aegean Syllabaries.—Under the syllabic writings of the Aegean area can be included the still undeciphered Cypro-Minoan and the deciphered Cypriote syllabaries of the island of Cyprus, the undeciphered syllabary of the disk of Phaistos in Crete and the undeciphered syllabary on about ten stone and metal inscriptions from Byblos.

The number of syllabic signs used in the Aegean systems varies from 56 to 90, and the signs are regularly of the type *ta, te, ti, tu, to*, that is, an initial consonant plus a different vowel. The difference between voiced, voiceless and aspirated consonants is not indicated in the writing. This type of syllabic sign is found in the Cretan, as well as in the hieroglyphic Hittite, writings discussed above.

Japanese Syllabary.—After a few centuries of cultural and commercial contact between China and Japan, the Chinese system of writing seems to have made its appearance in Japan in the 5th century A.D. The Chinese word signs were simply taken over by the Japanese and read not with their Chinese values but in Japanese. Thus, for example, the Chinese word sign *nan*, "south," was read in Japanese as *minami*, "south." The Chinese writing may have been well suited to a monosyllabic and isolating language in which grammatical forms are normally expressed by syntactical position rather than by special formatives. However, such writing was not suited to Japanese, which is polysyllabic and agglutinative and expresses grammatical forms by means of special formatives. Therefore, some of the Chinese word signs soon came to be employed as syllabic signs expressing the grammatical formatives of the Japanese language. Originally, the choice of the syllabic signs was unsystematic, and it was not until about the 9th century that a stable syllabary with 47 signs was developed, each expressing a consonant plus a vowel, with the difference in voice being fully indicated. In introducing a full syllabary the Japanese have never given up the logographic apparatus borrowed from Chinese, which they use along with their syllabary. (See JAPANESE LANGUAGE.)

Writings of Modern Primitive Societies.—Several systems, such as those of the Cherokees and Alaska Eskimos in America and of the Vai and Bamum Negroes in Africa, were developed in modern times under the influence of western civilization. Starting as a primitive logography, they passed through a logosyllabic stage, ending with syllabaries consisting of 85 (Cherokee) to 226 (Vai) signs.

LOGOGRAPHI, in Greek *logographoi*, writers of *logoi* or compositions of any sort, especially in prose. In Attic Greek the word signifies "professional speech writers"; in modern usage (since G. F. Creuzer, *Die historische Kunst der Griechen in ihrer Entstehung und Fortbildung*, 1803) it refers to pre-Herodotean writers of chronicles, from the doubtfully historical Cadmus of Miletus (q.v.) to Pherecydes Leros. All these make extensive use

of mythology, but their attempts at systematization and criticism are primitive. Their dialect is Ionic. Mention may be made of the following: Hecataeus of Miletus (q.v.); Acusilaus of Argos, who paraphrased in prose (correcting the tradition where it seemed necessary) the genealogical works of Hesiod; Charon of Lampascus (c. 450), author of histories of Persia, Libya and Ethiopia, of annals of his native town, and of the chronicles of Lacedaemonian kings; Xanthus of Sardis in Lydia (c. 450), author of a history of Lydia; Hellanicus of Lesbos (q.v.); Hippias and Glaucus, both of Rhegium, the first the author of histories of Italy and Sicily, the second of a treatise on ancient poets and musicians; and Damastes of Sigeum, author of genealogies of the combatants before Troy (an ethnographic and statistical list), and of short treatises on poets, sophists and geographical subjects. The work of Stesimbrotus of Thasos "On Themistocles, Thucydides and Pericles," though belonging to the same period, did not belong to the same category. It was really a political pamphlet, the first known of its kind, directed against the democratic imperialism of Athens.

LOGOS, a common term in ancient philosophy and theology. It expresses the idea of an immanent reason in the world, and, under various modifications, is met with in Indian, Egyptian and Persian systems of thought. But the idea was developed mainly in Hellenic and Hebrew philosophy, and the term is significant in the Gospel of St. John in the New Testament.

THE HELLENE LOGOS

To the Greek mind, which saw in the world a *kosmos* ("ordered whole"), it was natural to regard the world as the product of reason, and reason as the ruling principle in the world. So a Logos doctrine was more or less prominent from the dawn of Hellenic thought to its eclipse. It rises in the realm of physical speculation, passes over into the territory of ethics and religion and makes its way through three well-defined stages. These are marked off by the names of Heraclitus of Ephesus, the Stoics and Philo.

Heraclitus.—The idea of Logos acquires its first importance in the theories of Heraclitus (6th century B.C.), who, trying to account for the aesthetic order of the visible universe, broke away to some extent from the purely physical conceptions of his predecessors and discerned at work in the cosmic process a *logos* analogous to the reasoning power in man. On the one hand the Logos is identified with *gnome* and connected with *dike*, which latter seems to have the function of correcting deviations from the eternal law that rules in things. On the other hand it is not positively distinguished either from the ethereal fire, or from the *heim armene* and the *ananke* according to which all things occur. Heraclitus holds that nothing material can be thought of without this Logos, but he does not conceive the Logos itself to be immaterial. Whether it is regarded as in any sense possessed of intelligence and consciousness is a question variously answered. But there is most to say for the negative. This Logos is not one above the world or prior to it, but in the world and inseparable from it. Man's soul is a part of it. It is *relation*, therefore, as Friedrich Schleiermacher expresses it, or reason, not speech or word. And it is objective, not subjective, reason. Like a law of nature, objective in the world, it gives order and regularity to the movement of things and makes the system rational.

The failure of Heraclitus to free himself entirely from the physical hypotheses of earlier times prevented his speculation from influencing his successors. With Anaxagoras a conception entered which gradually triumphed over that of Heraclitus, namely, the conception of a supreme, intellectual principle, not identified with the world but independent of it. This however was *nous*, not

Logos. In the Platonic and Aristotelian systems too the theory of ideas involved an absolute separation between the material world and the world of higher reality, and though the term Logos is found the conception is vague.

With Plato the term selected for the expression of the principle to which the order visible in the universe is due is *nous* or *sophia*, not *logos*. It is in the pseudo-Platonic *Epinomis* that *logos* appears as a synonym for *nous*. In Aristotle again, the principle which sets all nature under the rule of thought, and directs it toward a rational end, is *nous*, or the divine spirit itself; while *logos* is a term with many senses, used as more or less identical with a number of phrases, *hou heneka* ("final cause"), *energeia*, *entelecheia*, *ousia*, *eidos*, *morphe*, etc.

The Stoics.—In the reaction from Platonic dualism, however, the Logos doctrine reappears in great breadth and is a capital element in the system of the Stoics (*q.v.*). With their teleological views of the world they naturally predicated an active principle pervading it and determining it. This operative principle is called both Logos and God. It is conceived of as material and is described in terms used equally of nature and of God. There is at the same time the special doctrine of the *logos spermatikos*, the seminal Logos, or the law of generation in the world, the principle of the active reason working in dead matter. This parts into *logoi spermatikoi*, which are akin, not to the Platonic ideas, but rather to the "material" *logoi* of Aristotle. In man too there is a Logos which is his characteristic possession, and which is *endiathetos*, as long as it is a thought resident within his breast, but *prophorikos* when it is expressed as a word. This distinction between Logos as *ratio* (reason) and Logos as *oratio* (oratory), so much used subsequently by Philo and the Christian fathers, had been so far anticipated by Aristotle's distinction between the "outside" *logos* and the *logos* "in the soul." It forms the point of attachment by which the Logos doctrine connected itself with Christianity. The Logos of the Stoics is a reason in the world gifted with intelligence, and analogous to the reason in man.

(X.)

THE LOGOS IN JUDAISM AND CHRISTIANITY

The problem of the Logos in the New Testament is that the fourth evangelist, in opening his Gospel with the statement, "In the beginning was the Word" (Logos), is undoubtedly recalling the opening words of Genesis, "In the beginning God created the heaven and the earth, . . . And God said . . ." but, in using the Logos absolutely to denote a divine hypostasis, is employing the term in a manner which is without parallel in the Bible and cannot be derived directly from the Old Testament.

The Hebrew Logos.—In the Old Testament "the word of the Lord" is another way of saying "God speaks," and means any communication of God to man, especially through a prophet (II Sam. xxiii, 2). "The word of the Lord came to . . ." can stand at the head of a prophetic book. In Hebrew thought the word carried with it the idea of activity and power. The word does not describe or comment, but effects what it utters (Isa. lv, 10-11). It judges, destroys and delivers (Jer. v, 14; Ps. cvii, 20). It is thought of as having a quasi-independent existence and an inherent power, especially in blessing and cursing (Zech. v, 3-4).

Alongside the word in the prophets, which is occasional, appears later the word in the Law, which is authoritative for all Israel for all time (Deut. xxx, 11 ff.). Later still the activity of the word in revelation is extended to cover the work of creation (Ps. xxxiii, 9). Subsequently Judaism sought to avoid anthropomorphism and stressed the transcendence of God over his creation, but maintained his contact with the world and his activity in creation and revelation by postulating divine agents, Wisdom, Word and Torah (Law). In the successive stages of the Wisdom literature a doctrine of Wisdom (grammatically feminine in gender) is developed. She has some sort of independent existence, is the divine artificer and draws men to God (Prov. viii, 14 ff.); she is identified with her supreme manifestation among the nations, namely the Torah possessed by Israel (Ecclus. xxiv, 7-23); and she is herself the presence of God, is before all light and is identified with the word of God (Wisdom of Solomon vii, 22-30, ix, 1-2, xviii, 15). The

identification of Wisdom with Torah was particularly the work of the rabbis, who speak of the Law in personal terms as divine and pre-existent with God, as light and life and as the source of truth. It is possible to parallel most of the statements about the Logos in the Johannine prologue with almost identical statements made either about Wisdom in the Wisdom literature or about the Torah in the rabbinic writings. While these agencies are to a greater or lesser degree personified, Jewish thought stopped short of hypostatization, and they are not conceived as independent metaphysical entities. The Johannine Logos is such an entity and would therefore appear to have its origin in a wider sphere than the Old Testament or orthodox Judaism. Its introduction in the prologue without explanation indicates that readers were expected to be familiar with it and that it had a considerable currency. Such a currency would correspond with the philosophical eclecticism and religious syncretism of the period.

Philo and Hellenistic Religion.—A notable example of such syncretism from the Jewish side was the Alexandrian Jew Philo (*q.v.*). He was not an original thinker but a compiler and, to judge from signs that he has incorporated material from predecessors in the same field, is the sole survivor of a widespread Jewish "philosophy" centred on, but not confined to, Alexandria. It aimed at converting the Greek world by presenting Judaism as the true philosophy by means of an allegorical and speculative interpretation of the Old Testament. (See JEWISH PHILOSOPHY.)

In Philo's voluminous works the term Logos occurs about 1,300 times, but it is impossible to harmonize the bewildering variety of his statements about the Logos into a single and consistent doctrine. At times he is dependent on Stoicism (*e.g.*, for such concepts as "the seminal Logos" and the "immanent and expressed Logos") but, unlike the more consistent type of Stoicism, differentiates the Logos from God as his work or image (*De specialibus legibus*, i, 81). He is dependent on Platonism when he identifies the Logos with the *kosmos noetos* or intellectual universe as a model for creation, or with the *topos* ("place") of the ideas considered as expressions of the mind of God. In general, Philo's Logos is a cosmological principle and, despite its frequency, hardly plays a living part in his theology, being an accommodation to Greek thought with the purpose of distinguishing between God as existing in himself and God as acting toward the cosmos. Although he speaks of it in personal terms (*e.g.*, as first-born son), the Logos can hardly be said to be personified, except where, in exposition of Old Testament texts, it is identified with figures such as Aaron and Melchizedek. The Logos is divine but not God, is with God, is light (*De somniis*, i, 75), water (*De posteritate Caini*, 127), manna (*Legum allegoriae*, iii, 172 ff.) and shepherd (*De agricultura*, 51). Thus there is a close similarity of symbolism between Philo and the fourth evangelist, and they move in the same world of thought; but a comparison of their writings makes any direct dependence highly improbable. Philo speaks generally of "the divine Logos" or "the Logos of God" rather than of "the Logos" absolutely.

The evidence of syncretistic religion outside Hellenistic Judaism is difficult to assess, being found in, or deduced from, sources which are widely different in character and of disputed date (*e.g.*, the *Hermetica* and the Mandaeen literature), are generally later than the 1st century A.D. and may in some cases be Christian or have been exposed to Christian or to Jewish influence. Moreover, fresh material, as it becomes available, tends to modify previous judgments. Thus the view that the Aramaic *memra* ("word") in the Targums on the Old Testament provides no parallel to the Johannine Logos is certainly correct, since the *memra* in the Targums is not a divine hypostasis but a theological device for avoiding the mention of the divine name; yet the "Gospel of Truth" discovered in the Jung codex contains elaborate speculation on the divine name as a divine hypostasis, which may go back to a 1st-century Judaism of a more heterodox kind than that of the Targums. Second-century Gnostic systems exhibit a mythological figure under various guises, such as Son of God, Image of God, *Nous*, *Anthropos*, among which is Logos. This figure has a cosmological function as mediator between the unknowable God and the world, brings gnosis to men and, in some cases, rescues men from a hostile

world. The fourth Gospel has this element of emphasis on the function of Logos as Saviour in common with such systems; as well as a general similarity of language and ideas, but lacks their speculation or polemic on the origin of the world or of darkness, and is not likely to be dependent on them. In Gnosticism Logos is one among many aeons, while the Johannine Logos is the one and only mediator.

The New Testament.—The affinities of the fourth Gospel may thus be various, but the clearest allusions are to Genesis, Wisdom and the Torah. Such polemic as there is in the prologue concerns the relation between the Logos and the Torah. This is evident from the conjunction of the statements that the incarnate Logos was "full of grace and truth" and that "the law was given by Moses, but grace and truth came by Jesus Christ" (i, 14-17). The character and functions of the Torah as pre-existent with God, as the source of life and the illumination of men, are transferred to Jesus, and thereby the Logos is for the first time fully personified. The term Logos will then owe less to current philosophical and religious speculation than to Christian theological reflection upon the person of Christ. The same path was trodden by other New Testament writers to the point where they might well have used the term itself. For St. Paul the Gospel is the word of God, which is also the word of Christ (II Cor. ii, 17; Col. iii, 16), which is Christ himself, in whom the fullness of the Godhead dwells (Col. i, 25-27, ii, 9) and who is the agent of creation (I Cor. viii, 6). In the Epistle to the Hebrews Jesus, who qualifies by an earthly career for an eternal priesthood, is presented as the author and sustainer of the universe and as the image of God (Heb. i, 1-4); and the author of the Apocalypse (Rev. xix, 13) identifies the exalted Christ with the Word of God, which elsewhere in his book means the revelation of God through Christ. The fourth Gospel represents the climax of such theological reflection. In this Gospel outside the prologue *logos* is used of individual statements made by Jesus (ii, 19-22); these are not, however, sporadic statements, but constitute together a single *logos* or message, which conveys truth and eternal life (v, 24, viii, 31, 43) and which is itself the *logos* of God (xiv, 24, xvii, 14). Further, for the evangelist this *logos* is not simply that which Jesus proclaims, but is inseparable from his person; he is the content of his own message and is himself the light, life and truth which he gives. Thus the identification of Jesus with the Logos is a short and almost inevitable step and will have been taken not by way of applying current metaphysical thought to the Gospel but in order to present in its widest cosmic significance—no doubt by means of a term which would be widely recognized—the person of Christ as Son of God and revealer of the Father.

Although the title Logos is confined to the prologue this does not imply that the prologue is an afterthought loosely attached to the Gospel, since what is predicated of the Logos in the prologue, viz., that he is pre-existent, life, light, is rejected by his own and gives grace and truth to those who receive him, is predicated of Jesus in the Gospel.

The Early Church.—The Logos doctrine which played a major, and in some respects an unfortunate, role in the earliest attempts of the primitive church to state Trinitarian belief was not a further development of the thought of the fourth Gospel but represents an importation from current philosophical thought and terminology. This was due to the apologists, whose aim in the face of a hostile world was to make the divinity of Christ intelligible to that world, to claim the world for Christ as its creator and to set forth Christianity as superior to, or the heir to, all that was best in pagan philosophy. Christ as the pre-existent Logos (1) reveals the Father to men and is the subject of the Old Testament manifestations of God; (2) is the divine reason in which the whole human race shares, so that Socrates and others who lived with reason were Christians before Christ; and (3) is the divine will and word by which the worlds were framed. Theophilus borrows the Stoic terms "immanent" and "expressed" Logos to denote Christ first as pre-existent with God before creation and then as uttered or generated for the purpose of creation; and the same idea is present in Athenagoras.

The apologists tended to start with Christ as a cosmological figure rather than as the revealer of the Father or as redeemer, and it

was impossible for them to avoid an impersonal conception of him as an attribute or function of God, or as a thought in the mind of God, which acquired self-expression and personality only in being uttered for the purpose of creation. They therefore inevitably subordinated him to God. Justin describes the Logos as flame derived from fire and as "numerically another thing." Subordination was carried further by Origen, who starts from a Greek philosophical conception of God as passionless and incomprehensible and, in attempting to do justice to such passages of Scripture as "the Father that sent me is greater than I," differentiates God as "cause" from the Logos as "caused" and calls the latter "a creature," although this was mitigated by his doctrine that the Son is eternally generated by the Father. Arianism pushed one side of Origen's thought to extremes and, working almost exclusively with the pagan idea of God as the immutable absolute and concentrating entirely on the cosmic function of the Logos, declared that since the Logos was susceptible of suffering he could not be God and that there was a time when he did not exist. Meanwhile there was another doctrine of the Logos in the church which was eventually able to escape the dangers of subordinationism. The Logos does not appear to have figured greatly in Gnosticism until Basilides, Valentinus and Heracleon, who were under Christian influence. It was possibly in opposition to their systems that St. Irenaeus and Tertullian developed a doctrine which started from Christ as the Son who reveals the Father through incarnation and redemption and used the term Logos for the more limited purpose of relating Christ as Son to the universe as its creator. It was this tradition in Athanasius and his followers which, when combined with Origen's doctrine of the eternal generation of the Son, led to the defeat of Arianism and ultimately to the conclusion that the scriptural and specifically Christian understanding of the Godhead was better expressed in terms of the relation of an eternally begotten Son to the Father than in terms of the relation of a pre-existent Logos to God.

LOG ROLLING: see BIRLING.

LOGROÑO, a Spanish city and province situated in the middle valley of the Ebro river. The city, which is the provincial capital (pop. [1960] 61,292 [mun.]), stands on the Ebro (the route from the Mediterranean to the Atlantic), 118 km. (73 m.) E. of Burgos by road. It is an ancient walled town, built on a hill, and has both old and modern quarters. It owed its origin and growth to its position on the pilgrim route to Compostela as much as to its production of wool. It is a trade centre for the agricultural district, and its wine is well known. Its industries include sawmilling, furniture, textiles and food processing.

LOGROÑO PROVINCE was formed in the administrative reorganization of Spain in 1833; formerly it was divided between Castile and Navarre. It contains nine judicial districts and 184 municipalities. Area 50,350 sq.km. (1,944 sq.mi.). Pop. (1960) 229,852. The dominant physical features are the Ebro and the mountains of the Sistema Ibérico, containing, among others, the sierras de Urbión (7,507 ft.), Cebollera (7,026 ft.) and La Demanda (6,342 ft.). Cameros is the mountainous zone, crossed by the Glera (or Oja), Najerilla, Iregua, Leza, Cidacos and Alhama rivers. La Rioja is the fertile lowland zone and contains such cities as Santo Domingo de la Calzada and Nájera.

The principal crops of the rich agricultural region are cereals, vines and, above all, horticultural produce from the irrigated *vegas* of La Rioja (153,000 ac.). The province was an important wool-producing area in the middle ages. There is a vegetable conserving industry. (M. B. F.)

LOHENGRIN, the knight of the swan, hero of the German version of a legend widely known in literature from the middle ages onward. The legend assumes different forms in different literatures, but the common framework, the oldest part of which probably derives from the fairy tale "The Seven Swans," is the

story of a mysterious knight who arrives in a boat drawn by a swan to protect a noble lady in distress, defeats her enemy and marries her, forbidding her, however, to ask his origin or his name; she later forgets her promise, and he leaves her, never to return.

The original home of the legend is unknown. The earliest known reference to it occurs in the 12th-century history of the crusades by William of Tyre, the source of the French version. In this *Roman du chevalier au cygne*, one of the *chansons de geste* (q.v.) based on the first crusade, the knight of the swan is called Helyas. He is the son of King Oriant of Lillefort, and the story of his brothers' metamorphosis into swans and his own escape from this fate follows the tale of the seven swans persecuted by a wicked grandmother. Helyas marries Beatrix of Bouillon in circumstances parallel to those in which Lohengrin marries Elsa of Brabant (see below). Their grandson, Godfrey, becomes ruler of Jerusalem, and from this historical event stems the adaptation of the whole story to the glorification of the house of Bouillon.

In English, a late 14th-century alliterative romance, *Chevalere Assigne*, retells the first part of the *Roman du chevalier au cygne* and takes over the explanation that one of the knight's brothers did not regain human shape but remained a swan, accompanying his brother Enyas (the "Chevalere Assigne") on his travels. The same story is told in the opening of *Helyas—Knyght of the Swanne*, a prose romance adapted from the French by Robert Copland in 1512, which relates the history of the knight, his brother the swan and his marriage into the Bouillon family.

The German story first appears at the end of Wolfram von Eschenbach's epic *Parzival* (c. 1210). Elsa, a young princess of Brabant, refuses all offers of marriage, saying that she will only give herself to a man sent by God. From the temple of the Holy Grail arrives a knight in a boat pulled by a swan, and he is hailed by the princess as her God-sent husband. He marries her, but makes her promise that she will not ask his name or origin. She pledges her word but some years later asks the forbidden question. The swan returns, and the knight goes back to the Grail castle. His name was Loherangrin, the son of Parzival, king of the Grail.

The story is expanded into an epic of some 760 strophes in the anonymous Middle High German *Lohengrin*. This was the main source used by Wagner for his opera. The opening is in a Thuringian dialect, but most of the poem is the work of a Bavarian poet who gives the story a historical context in the age of the German king Henry the Fowler (876?–936) and elaborates the realistic content at the expense of the romantic legend. *Lohengrin*, composed between 1275 and 1290, is related to the contemporary poem known as the *Wartburgkrieg*: here the story is put into the mouth of Wolfram von Eschenbach who is made to recite it during the famous singers' contest at the Wartburg, seat of the Thuringian landgraves: certain gaps in the story of the *Wartburgkrieg* can be filled from passages in *Lohengrin*; and the ten-line stanza known as *Klingsors Schwarzer Ton* is common to both works. Other medieval German versions of the story, which ultimately rest on the same passage from Wolfram's *Parzival*, include Konrad von Würzburg's *Schwanritter* (based on a French model) and the anonymous 15th-century epic *Lorengel*, which still uses *Klingsors Schwarzer Ton*.

Through its alignment with a specific historical period, its integration into the Wartburg story and its association with the Holy Grail and thence with the Arthurian legend, the Lohengrin story has become part of German popular tradition. In particular it has become linked with the town of Cleves, whose rulers took the swan as their crest, and where the *Schwanenturm* on the castle and a statue of the knight and his swan perpetuate its memory.

See R. Jaffray, *The Two Knights of the Swan* (1910); R. Heinrichs, *Die Lohengrindichtung und ihre Deutung* (1905). Both contain details of text editions and further critical studies. (Rd. J. T.)

LOIN, that part of an animal lying between the upper part of the hipbone and the last of the false ribs on either side of the backbone; hence the butcher's term for a piece of meat cut from that part of the body. The upper part of a loin of beef is known as the "surloin," commonly corrupted into "sirloin." In the plural the word is a term for the lower part of the human body at the junction with the legs. It is more or less synonymous with

flank, or that portion of the body bounded by the lower ribs, the backbone and the pelvis.

LOIRE, a *département* of central France, formed in 1793 of the old district of Forez and portions of pre-Revolutionary Lyonnais (q.v.) and Beaujolais. Area 4,799 sq.km. (1,853 sq.mi.). Pop. (1962) 696,348. It is bounded north by Saône-et-Loire, east by Rhône and Isère, southeast by Ardèche, south by Haute-Loire, west by Puy-de-Dôme and northwest by Allier. Most of the *département* consists of uplands formed of ancient crystalline rocks, rising west and east of the Loire valley to the mountains of Forez and Lyonnais, which reach culminating heights of about 5,000 ft. The Loire river, crossing the *département* from south to north, connects the downfaulted basins of Forez and Roanne, and traverses the crystalline highlands between in a gorgelike valley. The flat floors of these basins, covered with sedimentary material brought down from the surrounding highlands, are not very fertile and in their natural state were badly drained. Only after the mid-19th century was the Forez basin extensively reclaimed for farmland. The southeastern part of the *département* includes the synclinal depression of St. Étienne, etched out of relatively soft sedimentary rocks that include Coal Measures. On the highlands, which suffer from a cold, inclement climate and poor, acid soils, heath is extensive, but there is comparatively little forest. Where the waste has been reclaimed for farmland, pastoral activities prevail. The chestnut, once widely grown, no longer plays an important role in the rural economy. Urban development has provided a market for milk and meat, as well as for poultry products. Even in the lowlands agriculture is dominated by fodder crops. Grain is not extensively grown, and the vine is practically absent.

The chief wealth of the *département* is industrial, and the small coal field of St. Étienne has a historical importance for the location of industry out of all proportion to its present status in production. The easily accessible, outcropping coal seams were worked even in the middle ages. Although the seams are heavily faulted and the resources were never great, they provide coal of high quality, including some excellent for coking. With the advent of coke smelting, the area rapidly became the chief coal-mining district of France and the chief seat of the iron industry about the middle of the 19th century. It was the scene of the earliest railway lines in France. Production of coal has long passed its peak and is now small and declining. Iron smelting is no longer carried on, the only blast furnaces being situated off the coal field to the east and outside the *département* of Loire. A new coking plant, however, was installed after World War II at La Silardière. There are steelworks, and secondary metalworking and engineering industries remain important. Armaments, bicycles, automobiles, engine parts, hardware and electrical apparatus are typical products. Metal industries concerned with small articles such as locks, springs and files are often still organized in small workshop units rather than large factories. Small-scale and even domestic units persist side by side with factory organization in textiles, the other basic industrial activity of the area. The silk industry was introduced in the 16th century as a scattered rural activity. In modern times factory organization has developed with the application of power and most of the industry, which is especially concerned with the manufacture of ribbons and elastic web, is concentrated on or near the coal field. However, the use of electricity is again stimulating dispersal into the highland valleys that lie within the sphere of influence of Lyons. Throughout the *département* looms working for the Lyons textile interests are to be found. At Montbrison and elsewhere in the Forez basin are outlying establishments of metalworking and textile industries. Lacemaking is an old-established occupation of the Forez. Roanne (q.v.) is an important centre of cotton weaving, working up yarn brought from northern France. Mixed cotton and silk fabrics have become especially important. Urban growth has taken an elongated form, which corresponds to the coal field, from Firminy past St. Étienne, St. Chamond and Rive-de-Gier to the Rhône valley beyond the eastern limit of the *département*. St. Étienne (q.v.) is the chief node and shopping centre and is the capital of the *département*, which comes under the ecclesiastical, educational and juridical administration of Lyons. St. Étienne, Montbrison and Roanne are the centres of

the three *arrondissements* that comprise the *département*. There are important road and rail links between the Rhône and Loire valleys through St. Étienne. (AR. E. S.)

LOIRE-ATLANTIQUE (until 1957 LOIRE-INFÉRIEURE), a maritime *département* of western France, formed in 1790 from the southernmost part of the ancient duchy of Brittany (*q.v.*), together with the district of Retz in Vendée south of the Loire river. It thus lies astride, though mainly north of, the Loire estuary, and is bounded north by the *départements* of Morbihan and Ile-et-Vilaine, east by Maine-et-Loire and south by Vendée. Area 6,980 sq.km. (2,695 sq.mi.). Pop. (1962) 803,372. The broad lower valley of the Loire there cuts across the southward extension of the ancient crystalline rocks of the Armorican massif to enter the Bay of Biscay by a large estuary, encumbered by extensive sandbanks. The northern part of the *département* is drained independently by westward-flowing tributaries of the Vilaine. The north-west-southeast grain of the geological outcrops is shown by ribs of higher ground, notably the Sillon de Bretagne, and by the course of the Sèvre Nantaise, an important left-bank tributary that enters the Loire just below Nantes. Although the whole of the *département* is low-lying, the soils are generally poor. Some woodland and heath persists, but most of the land is enclosed as little fields, bounded by hedges, under grass and fodder crops, and the main emphasis of farming is upon cattle. Most of the *département* lies within the northern limit of the vine, which runs inland a little north of the Loire valley. Some alluvial land is intensively used for market gardens. In the Pays de Retz, south of the Loire, Lake Grand-Lieu, a shallow sheet of water of variable extent surrounded by marshes, is the scene of fishing and wild-fowl shooting. North of the Loire estuary there are extensive brine fields in the Pays de Guérande, behind the narrow peninsula by which former rock islets are attached to the mainland. On the seaward side La Turballe and Le Croisic are little sardine-fishing ports. These older activities of the district are being overshadowed by the development of the tourist industry, and La Baule-les-Pins on the sandspit has one of the finest natural bathing beaches on the French coast. The Angevin iron-ore deposits extend into the north of the *département* and are worked on a small scale in the vicinity of Châteaubriant. Tin is mined at Abbaretz, and elsewhere there are granite and slate quarries.

The main wealth of the *département* is associated with the Loire estuary, with its industrial ports. The old-established port of Nantes (*q.v.*), situated on the right bank at the head of the estuary, where sea and river navigation meet, flourished especially during the 17th and 18th centuries as one of the main centres of trade with France's colonies across the Atlantic. Its subsequent decline in status among French ports has been partly offset by modern industrial development. It has important engineering establishments, including marine engineering and locomotive works, as well as industries concerned with processing imported commodities. Extensive dredging is necessary to maintain the shipping channel among the sandbanks of the estuary up to Nantes, and after 1857 the outport of St. Nazaire (*q.v.*), 30 mi. to the west, was developed, with docks and long jetties that jut into the river mouth. It is a centre of naval shipbuilding and was used during World War II by the Germans as one of their main submarine bases. As such it suffered heavy bombardment, and the town was devastated in 1943. Nantes was also severely damaged during World War II, but the reconstruction provided the opportunity for the port layout and equipment to be modernized. Mineral oil has come to dominate the trade, and a large refinery has been established above St. Nazaire at Donges. At Trignac there is a fully integrated iron-and-steel works, and at La Basse-Indre there are other steel mills, chiefly concerned with the production of plates for shipbuilding. The canal from Nantes northwest through Brittany to Brest no longer carries much traffic. Nantes, ever since Roman times the leading urban centre of the area, is the seat of the *préfecture* of the *département* and of the bishopric, but the *département* comes under the *académie* and court of appeal at Rennes, the ancient capital of Brittany. The *département* is divided into four *arrondissements*, centred upon Nantes, St. Nazaire, Châteaubriant and Ancenis. Apart from the castle and the great

cathedral at Nantes, other noteworthy buildings in the *département* include the ruins of a medieval fortress with a Renaissance château alongside at Châteaubriant, the well-preserved ramparts and gates of the little town of Guérande, and a timber market-hall and attractive 13th-century castle at Clisson, overlooking a bridge across the Sèvre Nantaise. (AR. E. S.)

LOIRE RIVER (ancient LIGER), the longest river of France, is 1,020 km. (634 mi.) from source to mouth and has a maximum rate of discharge only exceeded, among French rivers, by the Rhône. With its tributaries it drains an area of about 47,000 sq.mi. or more than one-fifth of France. Its course may be divided into three major sections:

1. Upper section: the Massif Central. The river rises at about 4,300 ft. in the Cévennes, actually flowing southward initially from the region of Mont Mézenc, but after 10 mi. it turns to flow generally northward, in a valley cut deeply in granitic rocks, toward the basin of Le Puy. There it encounters an area of Tertiary sediments, together with rocks of recent volcanic origin, but the Tertiary cover is thin and the underlying granites are exposed in places. At Le Puy the elevation of the river is about 2,000 ft. It leaves the basin by a series of fine gorges through granites, and after about 80 mi. reaches the Plaine du Forez at about 1,200 ft. Like the basin of Le Puy, this is another enclosed lowland area floored by sandy Tertiary beds and river alluvium across which the Loire has entrenched its course. The Plaine du Forez terminates in the north against a mass of Carboniferous slates and igneous rocks, through which the Loire cuts a picturesque gorge with waterfalls, such as the Saut-de-Pinay, at a height of 1,000 ft. The river then enters a third basin of Tertiary rocks, that of Roannais. The floor of this basin slopes gradually northward with the river deeply incised. The river skirts a southerly projection of the old rocks of Morvan below Digoin, and the Tertiary basin widens to join with the Limagne.

2. Middle section: the Paris basin. Nearly half the course of the Loire is over the Secondary and Tertiary rocks of the Paris basin. Below Decize the Loire reaches Jurassic rocks, first crossing a small outcrop of Lias clay around Nevers. Just below Nevers, at a height of 525 ft., the Loire is joined on the left bank by its longest tributary, the Allier (*q.v.*). Its course then lies through a region of low hills of the Middle and Upper Jurassic series (Côtes du Nivernais on the east), across a narrow belt of Gault clay and, below Cosne-d'Allier, into the Chalk country (Collines de Sancerrois and Puisaye on either side of the river). After a further 20 mi. it reaches the main Tertiary outcrop of the southern Paris basin. The Chalk reappears around Blois and forms the valley sides for 110 mi. down to Les Ponts-de-Cé, where the Loire finally leaves the Paris basin. Throughout its course in the Paris basin, the river flows in a broad trench up to 6 mi. wide but occasionally narrowing to about 1 mi.; e.g., below Blois. The river is characteristically braided and meandering; in summer, the season of low water, the channels are rarely more than a few feet deep, and many banks of sand and gravel, fringed with willows and osiers, appear. But in winter the river becomes a raging torrent, with a discharge at times exceeding 300,000 cu.ft. per second. Hence much of the valley is diked below Blois, and bridges need to be lengthy and strongly built. At Tours the main road bridge is 1,400 ft. long. Between Tours and Saumur the river is joined by three important left-bank tributaries, also rising in the Massif Central: the Cher, Indre and Vienne (*qq.v.*). The characteristic appearance of the countryside of the middle Loire is green and well wooded; oak forest is most widespread, though in a few sandy upland areas birch and pine are more common, together with bracken and gorse. Along the rivers, poplars, alder and willow provide attractive borders. A great deal of the country is cultivated, including a considerable amount of meadowland and many orchards and vineyards; there are also tracts of parkland surrounding the famous châteaux.

3. Lower section: the Loire in Brittany. The river enters a region of old rocks (southern Brittany) at Les Ponts-de-Cé, 90 mi. from the sea but only 46 ft. above sea level. Four miles downstream it is joined by the large right-bank tributary of the Maine (*q.v.*). From there to the bend at Ingrandes it occupies a trench

up to 2 mi. wide cut in Paleozoic slates. Below Ingrandes the valley widens in Coal Measure shales toward Ancenis, but then contracts again to a narrow section (about $\frac{1}{2}$ mi. wide) in Pre-Cambrian schists around Champstoceaux. Downstream to Nantes the valley is somewhat wider in shales. Below Nantes a ridge of granite approaching the north bank maintains a relatively narrow valley. Even at Le Pellerin, 10 mi. below Nantes, the valley floor is only 1 mi. wide. The estuary, containing much marshland but dredged and diked where necessary, begins at Le Pellerin. The valley sides are still well marked, and St. Nazaire on the north shore is built on another outcrop of granitic rock.

Navigation and Commerce.—The Loire has only poor navigation above Nantes because of the great difference in discharge between summer and winter, the shallowness of the river in summer and the variable channels of its middle course. The main flood period is November–April, following winter rains and snow melt in the Massif Central, when much sand and gravel is brought down to choke the channels. The maximum discharge at Nevers is about 190,000 cu.ft. per second; at La Charité, 340,000; and at Nantes, 210,000. From the estuary up to Nantes a minimum depth of 30 ft. is maintained, but upstream the mean depth is usually less than 3 ft. and the minimum depth in many places is as little as 1 ft. Consequently, there is no regular navigation for about half the total length of the river. Yet the need for an east-west waterway across central France has often been stressed, and efforts were made after World War I to control the river and stabilize one main channel. By the 1960s the efforts had been only partially successful. The main stretch used for river craft is from the estuary up to the Vienne confluence just above Saumur. In the Massif Central section a lateral canal was constructed from Roanne downstream to Briare with a minimum depth of 6½ ft., but apart from traffic connected with the textile industries of Roanne, it is not greatly used. Another canal links Briare with the Seine river system and formerly handled quantities of timber, limestone and gravel for transmission to northeastern France and other parts of the Paris basin.

Several large towns lie at bridging points on the Loire, among them Nevers, Orléans, Blois and Tours, the largest town in the southern half of the Paris basin, located on a low-lying neck of land $\frac{1}{2}$ mi. wide between the Loire and the Cher. In the lower section of the river, Nantes is an ancient port and was the leading port of France in the 18th century. The river channel below Nantes is subject to severe silting, and in the 19th century a canal was cut along part of the left bank, but this has since been abandoned. Dredging has greatly improved navigation, and ships of 30 ft. draft can dock at most stages of the tide. Nantes handles nearly 4,000,000 tons of freight annually, of which over half consists of crude oil en route to local refineries. It is the lowest bridging point of the Loire. St. Nazaire on the estuary was originally a fishing port, but now possesses important docks which serve ships unable to negotiate the estuary up to Nantes. Its main function is as an outport, and it handles principally coal, oil and other raw materials.

(C. E.M.)

LOIRET, a *département* of north central France, formed in 1790 out of the ancient province of Orléanais (*q.v.*). It is bounded north by Seine-et-Oise, northeast by Seine-et-Marne, east by Yonne, south by Nièvre and Cher, west by Loir-et-Cher and northwest by Eure-et-Loir. Area 6,812 sq.km. (2,630 sq.mi.). Pop. (1962) 389,854. The *département* is low-lying and is traversed from east to west in a sweeping arc by the broad valley of the Loire river from above Briare to below Beaugency. The northern portion of the *département* is drained by left-bank tributaries of the Seine, the Loing and the Essonne. The Loiret, which gives its name to the *département*, is a short stream which emerges from springs south of the Loire in the park of the Château de la Source and after a course of only 8 mi. returns to the Loire a large quantity of water lost by seepage higher up the valley. The valley of the Loire, 4 mi. wide at Orléans, with a flat floor covered by light, sandy alluvium, is a strip of extremely intensive cultivation. Divided into small plots, the land is devoted to market gardens, nurseries and rich meadows, with vineyards and orchards along the valley sides. Beyond the well-defined *val*, with its dense popula-

tion of small holders, are extensive areas where an overspread of Tertiary debris brought down from the siliceous rocks of the Massif Central to the south is responsible for infertile soils, poor drainage and long persistence of woodland and waste. Within the great curve of the Loire valley is part of the marshy, mere-studded district of Sologne, on the right bank is the Forêt d'Orléans and in the northeast of the *département*, east of the Loing valley, is another infertile district, Gâtinais. North of the Forêt d'Orléans, however, the limestone platform emerges and its *limon* soil gives the rich grain lands of Beauce (*q.v.*). Another fertile tract reminiscent of Beauce extends west of Montargis between Gâtinais and the Forêt d'Orléans.

There is little industry in the *département* but Orléans has a variety of light manufactures including agricultural implements, and in the 1950s an important development of rubber manufacture took place nearby at La Chapelle-St. Mesmin. The towns are primarily agricultural market centres, with added importance attaching to those at historic crossings of the Loire, notably Gien and Orléans. Before the improvement of land communications in the 19th century the Loire waterway was of great importance in France and Orléans flourished as a river port, situated on the great northward bend of the river. The main railway line from Paris to the southwest and the arterial road cross the Loire there. In the southeast of the *département*, Briare is the northern end of the lateral canal of the Loire and thence the Canal de Briare, completed in 1642, connects the Loire with the Seine by the Loing valley. These waterways are no longer active, such traffic as persists being mainly southward-bound coal. At Sully-sur-Loire is a fine medieval château, rebuilt in the early 17th century by Henry IV's famous minister, the duc de Sully. The great Romanesque abbey church at Saint Benoît-sur-Loire, on the site of the earlier Benedictine abbey to which the relics of the saint were brought in the 7th century, and the fine 9th-century church of Germigny-des-Prés nearby are noteworthy reminders of the cultural importance of the Val de la Loire in the early middle ages.

Orléans (*q.v.*), the capital of the *département*, is the centre of the bishopric that is coextensive with it. Orléans, Montargis and Pithiviers are the centres of the three *arrondissements* into which the *département* is divided. The *département* is served by the appeal court at Orléans, but for administration of education it comes under the *académie* of Paris. (AR. E. S.)

LOIR-ET-CHER, a *département* of north central France, was formed in 1790 from the Dunois, Vendômois and Blésois portions of Orléanais (*q.v.*), with the addition of portions of Touraine and Perche. It is bounded north by Eure-et-Loir, northeast by Loiret, southeast by Cher, south by Indre, southwest by Indre-et-Loire and northwest by Sarthe. Area 6,422 sq.km. (2,480 sq.mi.). Pop. (1962) 250,741. The Loire river crosses the centre of the *département* from northeast to southwest past Blois. North of its valley the *département* extends across the limestone platform of Petite Beauce to the valley of the Loir river and beyond to the hills of Perche. South of the Loire the flat, ill-drained district of Sologne reaches almost to the valley of the Cher river, which crosses the southernmost part of the *département*. The *val*, or broad trench of the Loire valley, floored with light, sandy alluvium, is a patchwork of small holdings. Favoured by a soft climate, with mild, damp winters and warm, sunny weather persisting late into autumn, it is intensively cultivated with fruit, vegetables and vines. Even before the development of modern communications it had become an area of specialized vine growing, using the navigable waterway to distribute its products. Although wine is still important, the area under the vine is much less than before the phylloxera plague of the late 19th century, and an increasing amount of the valley floor is devoted to market gardens. Asparagus is an important crop on the more sandy tracts there and to the south in parts of the Sologne that have been reclaimed. North of the valley Petite Beauce, like Beauce itself, is rich grain land because of the fertile *limon* soil that covers the flat limestone platform, but to the southwest, with a change to less fertile soils, it gives way to the Gâtine de Touraine. The *département* is agricultural, with no important mineral wealth, little manufacturing and few towns. The Loire is no longer much used for navigation. Blois (*q.v.*), dominated by

the great castle that was a favourite royal residence in the 16th century, is the capital of the *département*, the centre of the bishopric and by far the largest town, although its population (1962) was 30,081. Vendôme, in the Loir valley, and Romorantin, on the southern edge of the Sologne, with Blois are centres of the three *arrondissements* into which the *département* is divided. The *département* comes under Paris for the administration of education and under the court of appeal at Orléans. Some of the most magnificent and justly famous Renaissance castles of France are situated in the *département*. The great castle of Blois, surrounding a vast courtyard, houses a fine art collection. Chambord has a grandiose façade and four massive round towers rising above the Cosson river. Chaumont (once owned by Catherine de Médicis), Avaray, Menars, Cheverny and Beaugard are other fine examples of 16th- and 17th-century châteaux, with rich furnishings and decorations. Vendôme has the ruins of a feudal castle and also a fine belfry in its church of the Trinity, and Romorantin, besides the ruins of a royal residence of the 15th and 16th centuries, has many picturesque old houses. Much of the old part of Blois, which was especially rich in old domestic architecture, was destroyed in 1940. (AR. E. S.)

LOISY, ALFRED FIRMIN (1857–1940), French Catholic theologian, biblical scholar and founder of modernism in France, was born on Feb. 28, 1857, of peasant parents in Ambrière (Haute-Marne). In 1874 on his own decision he entered the seminary at Châlons-sur-Marne and was ordained priest in 1879. While at the Institut Catholique from 1881 his study of the Bible, together with the influence of E. Renan's lectures, caused him to doubt Roman Catholic dogma. In 1889 he became professor of Sacred Scripture at the Institut, but the publication in his periodical *L'Enseignement biblique* of his critical views on the development of the Old Testament canon and the historical value of Gen. i, 1 caused his dismissal in 1893. As chaplain to the Dominican girls' school at Neuilly and afterward in seclusion at Bellevue he published numerous articles on historical aspects of the Bible, one of which, *La Religion d'Israël* (1900), was condemned by the cardinal archbishop of Paris, F. M. B. Richard. In 1900 Loisy became lecturer at the École Pratique des Hautes Études and in 1902 published his *Études évangéliques* and *L'Évangile et l'église* in reply to A. von Harnack's *Wesen des Christentums*; he combined an eschatological interpretation of early Christian teaching with justification of later ecclesiastical development. Although the latter publication was condemned by François Cardinal Richard (1903), Loisy published in 1903 his voluminous commentary on the Fourth Gospel, which he regarded as an allegorical account of Christian faith written at the end of the 1st century. The same year this and four other works were placed on the Index, and Loisy resigned his lectureship. After his *Les Évangiles synoptiques* (1907–08) Loisy was excommunicated, having previously received several warnings. As professor of the history of religions at the Collège de France (1909–30), he continued his controversial writings under the influence of German form criticism, moving gradually further away from traditional Christianity toward a faith in the creative power of humanity, but finally returning to the adoration of God as spirit. In 1912, 1916, 1920, 1923 and 1924 respectively he published his commentaries on Mark, Galatians, the Acts, Revelations and Luke. His *Les Mystères païens et le mystère Chrétien* (1919 [1914]) and *La Religion* (1917) maintain the influence on Christianity of pagan religions. He died on June 1, 1940. See also MODERNISM, ROMAN CATHOLIC.

See F. Heiler, *Der Vater des Katholischen Modernismus* (1947); M. D. M. Petre, *Alfred Loisy, His Religious Significance* (1944); A. Houtin et al., *Alfred Loisy* (1961). (W. G. KÜ.)

LOJA, the southernmost highland province of Ecuador, bounded on the west by Peru, on the north by El Oro and Azuay, on the east by El Oriente and on the south by Peru. The area of the province is 4,445 sq.mi., and its population (1962) was 285,448. Its capital is Loja. The population is concentrated in the basin of Loja and the valley of the Río Catamayo. In the area surrounding the city of Loja the chief land use is for growing maize (corn) and feeding dairy cattle. Wheat, barley and potatoes

are grown on the steep mountain slopes, and irrigated sugar cane is raised in the deeper valleys. Beef cattle are pastured in the mountains southwest of the capital, with sheep on the higher slopes. Woolen blankets are woven in the towns. The Inter-American highway extends southward as far as Loja. (P. E. J.)

LOJA, a town in Granada province, region of Andalusia, Spain, 58 km. (36 mi.) W. of Granada by road. Pop. (1960) 25,976 (mun.). Loja lies in the plain of the Genil river between the steep cliffs of the Sierra del Hacho and the Sierra de Loja or de las Cabras. It is a picturesque town and occupies a key position on the route to Granada. It has walls and a fortress, and there are churches and other monuments of the 16th century. It is on the railway from Granada to Algeciras. The main crops are cereals, olives and vegetables. Many factories manufacture olive oil. The town is of Roman origin and was important under the Moors. (M. B. F.)

LOKEREN, a town in the province of East Flanders, Belg., is situated on the Durme river, 22 km. (14 mi.) E.N.E. of Ghent. Pop. (1961) 25,819. The church of St. Lawrence (1721) has a carved pulpit by T. Verhagen and a modern carillon. Other notable buildings include the town hall (1761) and several Flemish Renaissance houses. Lokeren's early importance dates from the granting of a weekly market in 1555. Hat manufacturing, important in the early 19th century, slowly declined and was replaced by *couperie de poils*, the shearing of rabbits and the preparation of their fur for use in felt manufacture. By the beginning of World War II, Lokeren enjoyed an almost complete monopoly of this trade. Other industries include textile and rope manufacture. Lokeren is connected by rail with important points in Belgium. (V. V.)

LOKI, in Teutonic mythology, a cunning trickster. He is represented as the companion of the great gods Odin and Thor, helping them by his cunning but sometimes causing embarrassment to them and to himself. He also appears as the enemy of the gods, entering their banquet uninvited and demanding their drink; he is the principal cause of the death of the god Balder (*q.v.*). He is punished by being bound to a rock. The character has many points of resemblance with Prometheus (*q.v.*) and Tantalus.

The figure of Loki remains obscure; there is no trace of a cult and the name does not appear in place names. (K. C. K.)

LOLLARDS, in late medieval England, a name given to holders of certain religious tenets deriving from the teachings of John Wycliffe (*q.v.*). The term comes from Middle Dutch *lollaerd*, "a mumbler" or "mutterer"; it had been applied before Wycliffe's time to the Flemish Beghards and other continental groups suspected of combining pious pretensions with heretical belief. As early as 1382 it was used in an anti-Wycliffite sermon by the Irish Cistercian Henry Crump, while in 1387 the bishop of Worcester, Henry Wakefield, gave it official currency in a mandate against five heretics.

Early History.—The earliest Lollard group consisted of the Oxford scholars who showed allegiance to Wycliffe's doctrines c. 1380; they were headed by Nicholas of Hereford of Queen's college, to whom is attributed the first Lollard translation of the Scriptures. His associate Philip Repingdon, an Augustinian canon of St. Mary-in-the-Fields, probably carried the movement to Leicester, where by 1382 William Swinderby led a group of lay adherents and went forth to preach in neighbouring towns. Though Wycliffe himself was still writing at Lutterworth, no solid evidence supports the tradition that he personally sent out "poor preachers." In Nov. 1382 Archbishop William Courtenay assembled convocation at Oxford and there forced the academic Lollards into submission. Repingdon conformed with enthusiasm and ultimately, as bishop of Lincoln, became an active persecutor. Hereford was excommunicated, fled to Rome and appealed in vain against his sentence; arrested on his return, he recanted and by 1393 had also become a champion of orthodox belief. In 1390–92 Swinderby was still being pursued by authority and sheltered by sympathizers in the Welsh marches. At this stage the prime agent was Wycliffe's former secretary John Purvey, who probably compiled the second

translation of the Bible, one far more attractive and idiomatic than that by Hereford. Despite Courtenay's apparent triumph, the sect continued to multiply among townsmen, merchants, gentry and even among the lower clergy. Several knights of the royal household gave their support, while vociferous partisans, concerned especially to disendow the church, emerged in the house of commons.

Lollard Beliefs.—The most complete statement of early Lollard teaching appears in the *Twelve Conclusions*, drawn up, originally in English, to be pressed upon the parliament of 1395. They began by stating that the church in England had become subservient to her "stepmother the great Church of Rome." The present priesthood was not the one ordained by Christ, while the Roman ritual of ordination had no warrant in Scripture. Clerical celibacy occasioned unnatural lust, while the "feigned miracle" of transubstantiation led men into idolatry. The hallowing of wine, bread, altars, vestments and so forth was related to necromancy. Prelates should not be temporal judges and rulers, for no man can serve two masters. The *Conclusions* also condemned special prayers for the dead, pilgrimages and offerings to images; they declared confession to a priest unnecessary to salvation. Warfare was "express contrarious to the New Testament, the which is a law of grace and full of mercy." Vows of chastity by nuns led to the horrors of abortion and child murder. Finally, the multitude of unnecessary arts and crafts pursued in the church encouraged "waste, curiosity and disguising."

Though no particular manifesto ever commanded general adherence, the *Twelve Conclusions* cover all the main Lollard doctrines except two: that the prime duty of priests is to preach, and that all men should enjoy free access to the vernacular Scriptures. The movement's obvious attraction lay in this last provision and in its argument that the wealth, pride, ritualism and coercive powers of the church stood at variance with the recorded practices of Christ and the apostles. Its weaknesses sprang from bibliolatry and the vagaries of uninstructed private judgment. Though modern knowledge of Lollard extremist fundamentalism derives largely from such hostile writers as Bishop Reginald Pecock and Thomas Netter, the movement inevitably acquired a fringe of cranks. From its early days it also tended to discard the scholastic subtleties of Wycliffe, who probably wrote few or none of the popular tracts in English formerly attributed to him.

Fluctuations During the 15th Century.—The personal opinions and political needs of the Lancastrian kings induced them from the first to support the bishops in a campaign to obliterate the heresy. In March 1401 Archbishop Thomas Arundel forced Purvey into submission and induced convocation to condemn William Sawtre (Sawtre), who was in fact burned a few days before parliament passed the statute *De haeretico comburendo*. This measure stipulated that a heretic convicted by the spiritual court and refusing to recant, or relapsing after recantation, must be handed over to the civil power and suffer burning. The persecution, though reinforced in 1407 by Arundel's new purge at Oxford, failed to stifle Lollardy or to abash the boldness of its supporters in parliament. In 1410 these latter openly sought to modify the law of heresy, to dispossess the church and to endow the crown, together with many new earls, knights, esquires, universities and hospitals, from the spoils. Foremost among the lay converts was the distinguished soldier Sir John Oldcastle (*q.v.*), who was indicted in March 1413 for maintaining Lollard preachers and opinions. Arraigned before Arundel, he denied transubstantiation and the confessional. In October he escaped from the Tower of London and proceeded to organize a great march upon London by Lollards from many parts of the kingdom. On Jan. 9-10, 1414, Henry V assembled troops in St. Giles's fields and dispersed the rebels with little fighting. Though the elusive Oldcastle avoided arrest and execution until 1417, his rising resulted in a roundup of leaders and suspects so complete as to shatter the overt political influence of Lollardy. Driven underground, it operated henceforth chiefly among tradesmen and artisans, supported by a few clerical adherents. Between 1424 and 1430 over 100 Lollards were arraigned in the diocese of Norwich, while cases also proved common in Somerset and in parts of the diocese of Lincoln. Early in the century Scottish Lollards were being persecuted by the

inquisitor Laurence of Lindores, yet the sect persisted there until the Reformation.

In the spring of 1431 a fresh Lollard plot came to light; its ramifications proved surprisingly extensive, and it aimed at no less than the overthrow of the government and the disendowment of the church. The subsequent decline in the number of prosecutions may indicate merely a slackening of official pressure. Despite a few martyrs, Lollardy was neither demonstrative nor heroic; it flourished upon quiet evasion, and most of its adherents submitted tamely when brought into the ecclesiastical courts. In 1455 Reginald Pecock issued his *Repressor of Overmuch Wijting [Blaming] of the Clergy*, a powerful attack upon Lollard beliefs and especially upon their misuse of biblical texts. His analysis indicates that the emphases of Lollardy had not substantially altered since the time of the *Twelve Conclusions*.

Lollardy and the Reformation.—There can be little doubt that a Lollard revival began about 1500. Much of the detailed evidence comes from John Foxe, *Acts and Monuments* (1563), yet it is highly circumstantial and finds support elsewhere. In the London diocese, especially in Essex, Bishop Richard Fitzjames prosecuted about 50 Lollards in 1510 and about as many again in 1518. In Dec. 1514 the murder of the Lollard merchant Richard Hunne in the episcopal prison at St. Paul's immensely intensified anticlerical feeling in the city. Between 1527 and 1532 the bishops Cuthbert Tunstal and John Stokesley caused at least 218 heretics to abjure in that diocese; with few exceptions these heresies remained purely Lollard. Another major focus lay in the Chilterns, especially around Amersham and Buckingham, where in 1506-07 about 45 cases were presented to Bishop William Smyth of Lincoln. In 1521 Bishop John Longland occasioned in that area 50 abjurations and 5 burnings, and he continued active for another decade. The region was connected through a number of scattered communities in the Thames valley with others in Berkshire, Wiltshire and the Cotswolds. At Newbury about 140 heretics are said to have abjured together sometime during the early years of the century. Yet another centre lay in the Kentish clothing towns of Tenterden, Cranbrook and Benenden, where in 1511 about 46 Lollards were denounced to Archbishop William Warham, 5 being burned, the rest abjuring. Between these various areas active liaison existed; for example, Thomas Man, burned at Smithfield in 1518, had moved about instructing communities in East Anglia, the Chilterns, the Thames valley and Newbury.

Before 1530 the old Lollard and the new Protestant forces had begun to merge. Early Lutheran missionaries, like Robert Barnes, sold William Tyndale's New Testament to Lollard communities. When the writings of Luther began to enter England, Bishop Tunstal wrote to Erasmus, "it is no question of pernicious novelty; it is only that new arms are being added to the great band of Wycliffite heretics." The list of proscribed doctrines compiled by convocation in 1536 still retained a high proportion of characteristically Lollard beliefs, and even the conservative north was affected by the revival. Research into the archives of the diocese of York revealed proceedings against about 32 heretics under Henry VIII and against 45 others during the reign of Mary I. The uneducated majority of these offenders evinced neither Lutheran nor Zwinglian beliefs. Both before and after the advent of continental Protestantism, they attacked, on a Lollard basis, saint worship, images, relics, holy bread, holy water, sacred buildings and objects, and, above all, the doctrines of confession and transubstantiation. Nearly all these cases fail to appear in the actual registers of the archbishops of York but emerge from day-to-day court books, which in most other dioceses have been lost for that period. Hence it is not possible to estimate accurately the scope of the movement or even the number of trials. Yet this resurgence of an inveterate Lollardy, however negative and confused, undoubtedly amplified those complex undercurrents of dissent and anticlericalism that disturbed English society under Henry VIII. Late Lollardy coloured proletarian criticism of the church outside as well as inside the small Lollard communities; it facilitated the spread of Lutheranism, predisposed opinion in favour of the king's anticlerical legislation and, since it persisted beyond mid-century, may have helped create the psychological bases of popular nonconformity.

LOMAS DE ZAMORA, Argentine city and important suburb of greater Buenos Aires, located 10 mi. directly south of the federal district. Pop. (1960) 275,219. Its name and origin date from the end of the 16th century, when several of the low hills in the region were given in a grant to a Spaniard named Zamora who accompanied Juan de Garay in the second and permanent founding of Buenos Aires. The town developed as a residential area and with the growth of Buenos Aires merged into the suburban area of greater Buenos Aires. After 1940 it became a major industrial area with chemical, electrical and cement factories. (Js. R. S.)

LOMBARD, PETER (PETRUS LOMBARDUS) (c. 1100-1160), theologian and bishop, best known as "Master of the Sentences" (*Magister Sententiarum*), was born about 1100. Little is known of his life. After early schooling at Bologna he went to France to study first at Reims, then at Paris. From 1136 to 1150 he taught theology in the cathedral school of Notre Dame. He was present at the Council of Reims in 1148. In 1159 he was named bishop of Paris. He died in 1160. Besides the *Books of Sentences* (*sententiarum libri IV*), Peter Lombard wrote commentaries on Holy Scripture, sermons and letters. No special importance attaches to these writings. The *Sentences*, however, established his reputation and subsequent fame.

This work, written between 1148 and 1151, is a collection of teachings of the Church Fathers (*sententiae Patrum*), plus some opinions of medieval masters, arranged as a systematic treatise on sacred doctrine. Lombard takes due cognizance, throughout, of the role of reason in theology. His work marks the culminating point of a long tradition of theological pedagogy, and until the 16th century it was the official textbook of theology in the universities. Hundreds of scholars wrote commentaries on it (180 in England alone).

The contents of the *Books of Sentences* are as follows: book I deals with God, the Trinity, providence, predestination, evil; book II with angels, demons, the Fall, grace, sin; book III with the incarnation, the redemption, virtues, the Ten Commandments; book IV with the sacraments in general, the seven sacraments in particular, the four last things (death, judgment, hell, heaven).

The author shows originality in choosing and arranging his texts, in utilizing various currents of thought, in avoiding the extremes of both dialecticians and authoritarians, and above all in crystallizing the theology of the sacraments. He asserted that there are seven sacraments and that a sacrament is not merely a "visible sign of invisible grace" but also the "cause of the grace it signifies."

Peter Lombard's teachings encountered opposition during his lifetime and after his death. Later theologians rejected a number of his views. One opinion he held was officially censured, an opinion derived from Abelard's teaching that, in Christ, God is not man, but *has* humanity. This formula smacked of "christological nihilism" (a term applied to the heresy of adoptionism, according to which the Man, Christ, was not God's true Son, but his adopted son), and in 1177 Pope Alexander III condemned this error.

Notwithstanding, Peter Lombard was never regarded as unorthodox. Efforts to have his works condemned were unsuccessful. The fourth Lateran council (1215) even prefaced a profession of faith with the words "We believe with Peter Lombard. . ."

Peter Lombard's collected works may be found in J. P. Migne, *Patrologia Latina*, vol. 191 and 192. The best edition of the *Books of Sentences* (no English translation) is that by the Franciscans at Quaracchi, *Libri quattuor sententiarum*, 2 vol. (1916).

LOMBARD, a village in Du Page county, northeast Illinois, U.S., 21 mi. W. of the Chicago "loop," is located on gently rolling terrain at an altitude of 700-750 ft. It was named for Joseph Lombard, a Chicagoan, who platted the site in 1868. Incorporated as a village in 1869, it is still classified as such, even though it has a population of about 23,000.

Known as the "lilac village," Lombard has six parks, covering more than 100 ac. Lilacia park, bequeathed by Col. William Phum who collected lilacs as a hobby, has notable varieties of these flowering trees and shrubs. Lombard was one of the first communities in Illinois to give women the right to vote.

Lombard is mainly a residential suburb of Chicago and has little local industry.

For comparative population figures see table in ILLINOIS: Population. (D. A. P.)

LOMBARD LEAGUE (12th-13th century), the league of towns in northern Italy formed to resist the attempts by the Holy Roman emperors to reduce the liberties and jurisdiction of the Lombard communes. In 1164 Venice took the initiative in allying with Verona, Padua and Vicenza against Frederick I Barbarossa's policy (Veronese league); and in March 1167 Cremona concluded a league with Mantua, Brescia and Bergamo, which was joined in the same year by Milan, Lodi, Piacenza and Parma. On Dec. 1, 1167, the two leagues combined for 20 years in a new league, which then included 16 towns. The new alliance, the Lombard league, was governed by *rectores* representing its members and usually chosen from among their consuls (see COMMUNE [MEDIEVAL]). Further adhesions followed—thus in 1168, Novara, Vercelli, Como and Asti joined—but the league never included all the Lombard cities. It was backed from the beginning by Pope Alexander III, who saw in it a welcome ally against Frederick; and the league gave the name Alessandria to the fortified town that it built near Asti in 1168. The negotiations between Frederick and the league, begun soon after his unsuccessful siege of Alessandria in 1174-75, led to the preliminary peace of Montebello, in which the emperor practically abandoned his former program. No final agreement was reached, however, and on May 29, 1176, the league defeated him at Legnano. The peace of Venice between Frederick and the papacy (July 1177) was combined with a six-year truce between the emperor and the league, and this was followed by the peace of Constance of June 25, 1183. While the cities of the league recognized the emperor's overlordship, which found expression in the imperial investiture of the consuls, they retained their liberties and most of their jurisdiction and had the right to preserve or renew their alliance.

After Frederick Barbarossa's death (1190) the Lombard league was renewed by Milan, Brescia, Mantua, Vercelli, Verona, Novara and Treviso in 1198 and by Milan, Brescia, Piacenza, Bologna, Vercelli and Alessandria in 1208; but it was not until 1226 that it again became a powerful factor in Italian politics for a long period. When the emperor Frederick II summoned a diet to Cremona for Easter 1226 with the purpose of restoring imperial authority in northern Italy, the Lombard league was renewed for 25 years by Milan, Bologna, Brescia, Mantua, Padua, Vicenza and Treviso. They were soon joined by Piacenza, Verona, Lodi and other towns, as well as by Boniface II of Montferrat and Goffredo of Biandrate. Tacitly or openly supported by the papacy, the new Lombard league effectively opposed Frederick II and his reorganization of northern Italy. The crushing defeat that it suffered at his hands at Cortenuova on Nov. 27, 1237, proved no more than a temporary setback for the league. After Frederick's death (1250) it was dissolved. Renewed on the arrival in Lombardy of his son Conrad IV in 1252, it is last recorded in Jan. 1253.

LOMBARDO (LOMBARDI), the name given to a family of Lombard origin who practised as sculptors and architects in Venice in the 15th and 16th centuries, and who were largely responsible for the formation of the Venetian Renaissance style. Its most notable members were Pietro Lombardo (c. 1435–1515) and his sons Tullio (c. 1455–1532) and Antonio (c. 1458–1516). The son of Tullio Lombardo, Sante (1504–1560), also practised as an architect.

PIETRO LOMBARDO was born at Carona about 1435, and is first heard of in Padua, where he was active in 1464–67. There he executed the Roselli monument in S. Antonio (1467) and the Casa Olignani. About 1467 he transferred his studio to Venice, where he worked for the remainder of his life, producing a long succession of buildings and sepulchral monuments. The Roselli tomb derives from Florentine humanist monuments, and the earliest of his buildings in Venice, the church of S. Giobbe (after 1470) is also markedly Tuscan in character. Thereafter he developed a more individual architectural style, of which the first evidence is found in the church of Sta. Maria dei Miracoli (completed 1489). With its harmonious proportions and rich marble incrustation, this is one of the most distinguished Venetian churches of the early Renaissance.

In sculpture Pietro Lombardo also worked his way forward from the Niccolò Marcello (d. 1475) monument in SS. Giovanni e Paolo to the more complex and more typically Venetian Pietro Mocenigo monument in the same church (1476–81). In 1482 he executed the tomb of Dante for Ravenna and in 1485 began work on his most distinguished monument, the Zanetti tomb in the cathedral at Treviso, where the carving was in large part carried out by his sons. From 1498 until his death in June 1515 he served as *capomaestro* of the ducal palace in Venice.

TULLIO LOMBARDO, the elder of Pietro's sons, was born in Venice, probably about 1455. He is mentioned with his brother Antonio by the humanist Collaccio in 1475, and assisted his father in work on the Pietro Mocenigo monument in SS. Giovanni e Paolo. The figure sculpture in his most important work, the Vendramin monument from Sta. Maria dei Servi, now in SS. Giovanni e Paolo, is the peak of Venetian classicism; a beautiful figure of Adam from this tomb is now in the Metropolitan museum, New York. In 1525 he executed his best-known work, the recumbent figure of Guidarello Guidarelli at Ravenna. His last dated work is the Bellati monument in the cathedral at Feltre (1528). Tullio was also active as an architect, designing the Cappella dell'Argento for the cathedral at Ravenna (1515) and the cathedral at Belluno (1517) and working in this capacity at Mantua (1527). He died on Nov. 17, 1532.

ANTONIO LOMBARDO, the younger of Pietro's sons, seems to have been born about 1458 and was already active by 1475. He assisted his father and brother in Sta. Maria dei Miracoli, on the Zanetti and Vendramin monuments, and on the façade of the Scuola di S. Marco (for the reliefs on which he and Tullio were jointly responsible). In 1501 he received the commission for two reliefs for the chapel of St. Anthony in S. Antonio at Padua, only one of which was completed (1505). This reveals Antonio as a more restrained and in some respects more sensitive sculptor than his brother Tullio. Between 1504 and 1506 he worked on the tomb and chapel of Cardinal Zen (d. 1501) in St. Mark's, Venice. This was the first major work in bronze executed by a Venetian sculptor and was completed by Paolo Savin.

In 1506 Antonio Lombardo transferred his workshop to Ferrara, where he was employed by the Este and where he is last mentioned in 1516. There he was responsible for the carving of the celebrated Camerini d'Alabastro (alabaster chambers) in the Castello, which were decorated with mythological and other reliefs. An important group of carvings from this complex is in the Hermitage at Leningrad.

Venezia (1893); L. Planiscig, *Venezianische Bildhauer* (1921).

(J. W. P.-H.)

LOMBARDS, a Germanic people who from 568 to 774 had a kingdom in northern Italy. They appear in classical writings of the 1st century A.D. as one of a number of tribes who formed the Suebi. Their home was then evidently in northwestern Germany, on the left bank of the lower Elbe river. If distinctive types of late Iron Age pottery and brooches are rightly associated with them, their settlements extended both west and east of the medieval Bardengau, which, with its principal community Bardowiek (near Lüneburg), preserves the second element of their tribal name (Langobardas; classical Lat. Langobardi, medieval Lat. Longobardi). According to a tradition written down in the 7th century they arrived there from a more northerly home. The same source asserts that they got their name from their long, uncut beards; but a different explanation is possible.

Before A.D. 6, Roman soldiers had fought against them; in A.D. 17 they supported the Cherusci against the Marcomanni; and shortly after A.D. 47 they helped re-establish a deposed ruler of the Cherusci. About A.D. 166 Lombards were among the barbarians who attacked the Danube frontier. The main body of the Lombards, however, is generally thought to have pursued a settled pastoral existence in northern Germany until the beginnings of the great migrations late in the 4th century, and even after this others remained to be absorbed by the expanding Saxons. The tradition written down in the 7th century that the migration southward was associated with a change from leadership by a duke to rule by a king, in the person of Agelmund, may be authentic. The same source's account of the stages by which the Lombards moved to the middle Danube is extremely obscure. There is some archaeological evidence, however, that they established themselves successively along the upper Elbe and in the later Moravia, where in the mid-5th century they were temporarily part of the Hunnish empire of Attila.

At the end of 487 the kingdom of the Rugii, which roughly coincided with Austria north of the Danube, was destroyed and the Lombards occupied the area. Contact with the Ostrogoths and Franks brought them into touch with late Roman culture. The earliest examples of elaborately decorated brooches in which the styles and techniques current in these societies have in turn been adapted to Lombard taste appear in their graves shortly after this. In the early 6th century the Lombards temporarily expanded toward the Tisa river, which may have been one reason for the war fought c. 508 under their king Tato against the Heruli and their king Rudolf, which ended in the almost complete destruction of the Heruli. The Lombards then, according to their 8th-century historian Paulus Diaconus, "began of their own accord to seek occasions of war." At this period also they probably received their first Christian missionaries. When, later, they entered Italy they were certainly Arians; but there is evidence that at one time they had favoured orthodoxy and subsequently changed, possibly under Gothic influence. Tato was killed c. 510 by his nephew Waccho, who ruled for 30 years, his kingdom extending across the Danube as far as Lake Balaton. Shortly after 536 the Byzantine emperor Justinian I made a treaty with him directed against the Gepidae who held the country east of the Danube. But for nearly a decade the Lombards gained little or no advantage from it, since Waccho's successor, from c. 540 to 546, was a minor. In 546 Audoin began a new royal dynasty; and at the beginning of his

BY COURTESY OF THE TRUSTEES OF THE BRITISH MUSEUM
LOMBARD BROOCH (7TH CENTURY)
FROM TUSCANY, ABOUT 6 IN. LONG.
IN THE BRITISH MUSEUM

reign he and his subjects were allowed to establish themselves in the formerly Ostrogothic lands as far as and even beyond the Save. At that time, it seems, they began to adapt their tribal organization and institutions to the imperial military system of the period, in which a hierarchy of dukes, counts and others commanded warrior bands formed from related families or kin groups. For two decades intermittent wars with the Gepidae alternated with truces and the attempts of both sides to gain imperial support for their own ends. About 565 Audoin died. In the same year the Avars appeared in the west; with them Audoin's son and successor Alboin made a compact to destroy the Gepidae. The decisive battle (c. 567), however, was fought between the Lombards and the Gepidae only. The latter were destroyed and their king killed, and Alboin married his daughter Rosamund.

Even before this the Lombards seem to have had their eyes on Italy, where the Byzantine armies had recently overthrown the Ostrogothic kingdom. In the spring of 568, having arranged with the Avars that they could return to and reclaim their lands in Pannonia if they did not like Italy, they crossed the Julian Alps.

The Lombards' invasion of northern Italy was almost unopposed, and by Sept. 569 they had conquered all the principal cities north of the Po except Pavia. Subsequently Alboin sent armies across the Apennines; in 571 he may have threatened Rome itself, though only western Emilia and part of Tuscany were permanently conquered at this time. Simultaneously two other armies respectively occupied Spoleto with the land eastward to the Adriatic and Benevento with adjacent areas of southern Italy. Pavia fell in 572. Shortly afterward Alboin was murdered in revenge for having forced his wife to drink from her dead father's skull. The 18-month rule of his successor, Cleph, was marked by the ruthless treatment of the Italian landowners.

On his death the Lombards chose no successor. Instead the dukes, who with their followings had been or were now associated with one of the cities in the occupied area, exercised authority in their particular city-territories. Place names and archaeological evidence indicate that the war bands that settled south of the Apennines were fewer than those that settled in the Po valley and the northeast. But everywhere the Lombards were outnumbered by the native population, and they seem to have established themselves in groups in easily defended positions on the outskirts of the cities or in similar "castles" in the countryside. For a time they may have lived largely on tribute, though quite early many of them must have acquired lands of their own.

The ten-year "rule of the dukes" was later viewed as one of violence and disorder, in which the church suffered at least as much as the native landowners. In 584, however, threatened by a Frankish invasion which the dukes had provoked, the Lombards made Cleph's son Authari king; and when he died in 590 he was succeeded by Agilulf, duke of Turin, who married his widow Theodelinda, a Bavarian and a Catholic. A Franco-Byzantine alliance, which this marriage was partly intended to counter, had inflicted serious defeats on the Lombards by 590, but Agilulf was subsequently able to recover most of what had been lost. In the next decade Rome itself was threatened, first by the duke of Spoleto and subsequently by Agilulf, being saved only by the efforts of Pope Gregory I. By 605 the Lombards were in complete control of the Po valley and Emilia east of the Panaro; the Byzantines retained only the Venetian coastal strip, the Ligurian coast, the Po basin and the Adriatic coast southward, Perugia and the adjacent Apennine crossings, Rome and its neighbourhood, Naples and small areas in the southeast and southwest. In 643 a Lombard army under King Rothari (reigned 636–652) occupied Liguria.

When Authari became king, the dukes surrendered half their estates for the maintenance of the king and his court, and royal officials known as gastaldi were appointed to administer them and (eventually) to act as a check on the power of the dukes. Border duchies such as Friuli and Trento were always difficult to control, and except for relatively brief periods the dukes of Spoleto and Benevento were usually able to act independently of the king; but the internal weaknesses of the Lombard kingdom must not be exaggerated. By the 620s Pavia was emerging as something like a capital. The royal palace (built by Theodoric the Ostro-

goth) was the centre of an administrative organization whose officials and techniques, like the documents they wrote, owed much to Roman traditions as transmitted by the Byzantines. Rothari's "Edict" of 643, in which the laws of his people were recorded for the first time, illustrates many aspects of this "romanization"; but it also shows how tenaciously the Lombards maintained many of their Germanic customs—though some of these, such as vendetta, had been modified by Christian and royal influence.

The Lombards' Arianism helped to maintain their separateness from the king's Roman subjects. Theodelinda's Catholicism had little permanent influence except for her support of the foundation of the influential monastery of Bobbio. Arian bishops continued to exist in parts of northern Italy, and Rothari was actively anti-orthodox; it was only in King Perctarri's reign (671–688) and after the intervention of missionaries organised from Rome that the Lombards finally abandoned Arianism.

Theodelinda's line died out with the brutal Aripert II (reigned 700–712) and a new dynasty was raised to the throne. Its second representative, Liudprand, who reigned from 712 to 744, was probably the greatest of the Lombard kings. Until 726 he seems to have been concerned exclusively with the internal condition of his kingdom. Subsequently, helped by the internal dissensions resulting from imperial policies, he steadily reduced the area still under Byzantine rule; and he also made his authority effective in Spoleto and Benevento. The laws which he issued in 15 of the 31 years of his reign reveal an increase in royal power, a growing opposition to violent revenge and the greater importance of property transactions. Coins and documents from his court confirm the impression of a strong and effective monarch.

In 751 Ravenna and the remaining central Italian Byzantine territories were occupied by Aistulf (king 749–756), who then invaded the territory round Rome. On the appeal of Pope Stephen II (III), the Frankish king Pepin led two expeditions into Italy in 754 or 755 and 756, and compelled Aistulf to surrender to the papacy most of his conquests since 751. When in 772 Aistulf's successor Desiderius invaded these papal territories, Pope Adrian I sought the help of the Frankish king Charles (see CHARLEMAGNE). The latter entered Italy in 773 and after a year's siege Pavia finally fell to his armies. Desiderius was captured, the great men of the kingdom made their submission and Charles became king of the Lombards as well as king of the Franks.

The traditions and achievements of the Lombards were not forgotten with the disappearance of an independent kingdom. In the 780s Paulus Diaconus, himself of an old Lombard family, wrote their history from the beginning to the death of Liudprand; and in the 9th century the princes of Benevento, whom the Franks failed to subject, regarded themselves as maintaining the ancient traditions of the Lombard people. The Italian language includes a number of words of Lombard origin; and for at least two centuries the judicial institutions of northern Italy showed traces of Lombard influence. The Lombards also played a part in the development of later Germanic ornament (in the 7th century) though their contribution to the art of Italy was negligible. Finally many features of later Italian life which have Roman origins, such as the notariate, were transmitted via the Lombards.

LOMBARDY (It. *LOMBARDIA*), a region of northern Italy, is composed of the provinces of Bergamo, Brescia, Como, Cremona, Mantova, Milano, Pavia, Sondrio and Varese. Area 23,804 sq. km. (9,191 sq. mi.). Pop. (1961) 7,406,152. It is the leading industrial and commercial region of Italy and one of the country's best farming areas.

Physically, Lombardy may be divided into three zones: a northern, mountainous zone; a median, hilly zone; and a southern, plain zone. The northern zone is divided into the Alpine and the pre-Alpine zones. The Alpine zone, where crystalline rocks prevail, comprises part of the Lepontine and Rhaetian Alps, the Orontic

Alps, the Ortles and the Adamello. In the Bernina it reaches a height of 13,304 ft. and has many glaciers. The pre-Alpine zone, mostly calcareous, though also dolomitic, attains less elevated heights but occasionally rises above the 8,000-ft. line. It is particularly beautiful at some of its massifs, such as the Grigne. The hilly zone, partly composed of a morainic material with some morainic amphitheatres, is gently undulating. The alluvial plain, sloping northwest-southeast, is divided into high and low areas; the former has a gravelly soil, poor in superficial water; the latter, with plentiful moisture content, is separated from the former by the spring line where the waters, hidden in the subsoil at the higher level, gush out.

Lombardy has many rivers, all tributaries of the Po. The principal ones are the Ticino; the Adda, with its affluents the Brembo and Serio; the Oglio, with its affluents the Mella and the Chiese; and the Mincio. The Valtellina and the Brembana, Seriaria, Camonica, Trompia and Sabbia valleys are among the most beautiful in Italy. The region also has many Alpine, pre-Alpine and inframorainic lakes, containing all or part of Lake Garda, the largest lake in Italy, Lake Maggiore, the Lake of Lugano, Lake Como, Lake Iseo, Lake Idro, Lake Varese and the lakes of the Brianza (Pusiano, Annone, Alserio and Segrino).

The climate, though in the main continental, is variable, because of the great differences of height and the presence of large water areas; it is most continental on the lower plain at Milan, Pavia and Cremona. The rainfall, not less than 24 in. annually in the area near the Po, reaches 80 in. in the mountainous regions.

Lombardy has a larger population than any other Italian region and contains about 14.6% of the total population of Italy although it covers only 7.9% of the country's area. The population density is greatest in the pre-Alpine zone and on the plains, the areas of intense economic, agricultural and industrial development. A table giving area and population for the various regions will be found in the article ITALY.

Agriculture, especially on the plains, is industrialized, and high productivity is achieved by scientific use of fertilizers and by irrigation. Grasslands, where grass is mowed up to eight times a year in the *marcite* ("flooded meadows"), cereal growing (rice, wheat and corn) and sugar-beet cultivation are characteristic of the low plains; the higher plains grow cereals, green vegetables, fruit trees and mulberries. The hilly zone has fruit and chestnut trees; the climate and soil around the lakes are especially suitable for olive trees and limes. In the pre-Alpine zone vines grow at altitudes as high as 2,400 ft. above sea level, and on the Alps there is excellent grazing. In the Alpine hamlets cattle breeding is scientifically practised; about half of the cattle are milk producing. Pigs are also raised and sheep are bred for both wool and meat. Honey is another important product. Lombardy ranks third, after Veneto and Friuli-Venezia Giulia, in the production of silk cocoons.

A national park, of about 350 sq.mi., for the preservation of the indigenous animal life, was set up at Stelvio in 1935.

Lombardy is part of the industrial triangle of northern Italy, marked by the cities of Genoa, Turin and Milan. The Milan metropolitan area is known for steel and iron, automobiles and trucks, machine tools and machines, chemicals and pharmaceuticals made in Milan, Monza, Sesto San Giovanni and other centres. Brescia, Pavia and Cremona manufacture trucks, engines and machinery; Como, Legnano and Gallarate, textiles; the Brianza district, furniture; Vigevano and Varese, leather. Food industries are located in many of the smaller towns. Milan is the leading industrial city of Italy, its principal banking centre and its leader in wholesale and retail trade. The region's railway network radiates from Milan, which has through rail communications with Switzerland, France and Germany through the Simplon and St. Gotthard passes; with Turin and Paris via the Mont Cenis rail line; with Venice, Trieste and Yugoslavia to the east; with Genoa, Bologna, Rome and Bari to the south and southeast. Automobile expressways connect Milan with Turin, Genoa, Venice and Florence, and there are excellent highways throughout Lombardy.

For the history of Lombardy, see LOMBARDS; ITALY; see also references under "Lombardy" in the Index. (A. C.; G. K.H.)

LOMBOK, one of the Nusa Tenggara Islands, in West Nusa Tenggara province, Indonesia, lies due east of Java, with the island of Bali between it and the Javanese coast, the Lombok strait separating it from Bali. Lombok has an area of 1,826 sq.mi. Pop. (1961) 1,300,234.

Physical Geography.—The island is very mountainous, being divided for nearly its whole length by two mountain chains, separated by a valley, which is broken in the centre by a ridge of low hills. The southern chain, which runs from southeast to west-northwest, does not exceed 1,000 ft., but the northern chain, beginning with Gunung Wangsit, 11½ mi. N. of Ampenan, rises eventually to 12,352 ft. in Gunung Rindjani (the Peak of Lombok), one of the highest volcanoes of the Malay archipelago. Lower peaks flank the mountain, united by a plateau 7,200 ft. in height and containing a fine lake, Segara Anak. None of the many small rivers is navigable. The coast is very bold in places, with cliffs rising precipitously from the sea, but there are good anchorages in bays on the west and east coasts.

The flora includes, among the palms usual to the tropics, a great palm, a species of *Corypha*, which is a striking feature of the plains, and several Australian forms. The fauna comprises monkeys (*Macacus cynomolgus*), deer and wild pigs and many beautiful birds, large green pigeons, eight kinds of kingfishers, a ground thrush (*Pitta concinna*), grass-green doves, little crimson and black flower peckers, large black cuckoos, king crows, golden orioles and fine jungle cocks; dragonflies abound.

Lombok strait, which has depths exceeding 600 fathoms, marks the edge of the Asian continental shelf. The British naturalist Alfred Wallace in the mid-19th century drew a line from the strait northward, between Celebes and Borneo, and then passing eastward, between the Sangihe Islands and Mindanao, into the Pacific ocean, to denote the frontier between the Asian and the Australian regions; it has been known since as the Wallace line. It is supported by the fact that there are marked differences between the flora and fauna of Bali and Lombok, the barbets, fruit thrushes and woodpeckers of the former being practically unknown in the latter, while the cockatoos, honey suckers and mound builders (Megapodidae) of Lombok are equally foreign to Bali. Later observations, however, have established that some intermingling of species is taking place, and that Wallace's line cannot be applied strictly to all forms of life—to spiders, for instance, it cannot be applied at all. To be exact, Lombok, in a biological sense, denotes the beginning of a transitional area in which Asian forms of life are gradually supplanted completely by Australian forms.

People.—The population of Lombok is composed largely of Sasaks (Sassaks), the indigenous inhabitants of the island, of Malay origin and akin to the indigenous population of the neighbouring island of Sumbawa (q.v.); there are also some Balinese, mostly in the northwest, and a few Chinese traders. The Sasaks, who are Muslims, built villages and houses after the Balinese pattern and followed customs resembling those of the Balinese, under whose domination they came in the 17th century. Sasaks use the Balinese script for writing, and their literature consists of Javanese and Malay translations.

Industry is at a comparatively high level; clothes and mats are woven, and there are workers in gold, silver and iron. The people are also capable agriculturists, their rice and coffee cultivation having reached a fairly advanced stage.

Mataram, the chief town and trade centre, is a short distance inland from Ampenan, the main port of Lombok, on the western coast; landing there is difficult during the west monsoon. From Ampenan and the port of Labuanhadji, on the east coast, frequent steamer service is maintained with ports in Bali and Java, with Celebes (Makassar) and with Sumbawa, Sumba, Flores and Timor. There is good road communication, and the island has cable connection with Java by way of Bali.

History.—As early as 1640 Lombok was regarded by the sultan of Makassar as being under his rule. When his power was shattered by the Dutch in 1667, a Sumbawa chief endeavoured to impose his sovereignty on the island, with the peaceful assistance of the Dutch. Civil war in Sumbawa left Lombok the prey first of pirate adventurers from Makassar and later of the Balinese, who

planted colonies in north Lombok and set about establishing their rule. Balinese intervention began about 1692; Dutch endeavours to get the signatories to the Bongay treaty (see CELEBES: History) to take action to counteract it were unsuccessful, and eventually the Balinese succeeded in establishing four kingdoms in Lombok: Mataram, Korangasem, Pagasangen and Pagutan.

In 1843 Mataram entered into a contract with the Dutch. Friendly relations between them continued until 1872, when Mataram, looking upon itself as independent and not in suzerainty to the Dutch, refused to send its regular embassy to Batavia (Jakarta) and, in 1891, interfered in the domestic politics of Bali. At the same time it cruelly oppressed the Sasak population of Lombok, so that the latter made ineffectual attempts to throw off the Balinese yoke, finally invoking Dutch aid. This was given, and in 1894, after one expedition had met with disaster, a second was successful in overthrowing the government of Mataram. Lombok was made a division of the residency of Bali and Lombok, under an assistant resident at Ampenan, and was divided into two districts, East and West Lombok; a third district, Central Lombok, was created in 1898, the capitals of the three districts being at Mataram, Praja and Sisi.

During World War II Lombok was occupied by the Japanese. It became part of the republic of Indonesia after the war. See also SUNDA ISLANDS AND STRAIT; MALAY ARCHIPELAGO.

(E. E. L.; J. O. M. B.)

LOMBROSO, CESARE (1836–1909), Italian criminologist, whose interests centred on the relation between mental and physical disorders, was born on Nov. 18, 1836, at Verona. He studied at Padua, Vienna and Paris, and in 1862 became professor of psychiatry at Pavia, then director of the lunatic asylum at Pesaro and later professor of forensic medicine and of psychiatry at Turin, where he eventually filled the chair of criminal anthropology.

He held that the criminal population exhibits a higher percentage of physical and mental anomalies than noncriminals; and that these anomalies are due partly to degeneration, partly to atavism, or reversion to a primitive evolutionary stage. He contended that criminals can be identified by certain "stigmata" or physical characteristics. Although most of Lombroso's theories were discredited, he worked in a practical way for a more humane and constructive treatment of convicts. (See CRIMINOLOGY.)

His *Crime, Its Causes and Remedies* was translated by Henry P. Horton (1911). Lombroso died at Turin on Oct. 19, 1909.

BIBLIOGRAPHY.—T. L. Ferrero, *Criminal Man According to the Classification of Cesare Lombroso* (1911); M. E. Paul (trans.), *C. Lombroso, a Modern Man of Science* (1911); M. E. Wolfgang, "Cesare Lombroso," in H. Mannheim (ed.), *Pioneers in Criminology* (1960).

LOMÉNIE DE BRIENNE, ÉTIENNE CHARLES DE (1727–1794), French ecclesiastic who for 16 months held the all-important ministry of the finances under Louis XVI and subsequently created cardinal, was born in Paris on Oct. 9, 1727, of a Limousin family. After he entered the church his brilliant intellectual gifts and aristocratic connections secured him rapid advancement: he was appointed vicar-general to the archbishop of Rouen in 1752, bishop of Condom in 1760 and archbishop of Toulouse in 1763. He achieved prominence as a member of the *commission des réguliers*, which suppressed some of the minor monastic orders in France, and by his administrative ability at meetings of the estates of Languedoc. In 1770 he was elected to the Académie Française, but for a time his further advancement in the church was prevented by his attitude as a freethinker.

His rise to important ministerial office under Louis XVI was facilitated by the favour of the queen, Marie Antoinette, and by his role, in the first assembly of notables (Feb.–May 1787), as leader of the clerical opposition to the fiscal and administrative plans of Calonne. Early in May 1787 he was placed in control of finances in the former post of Calonne, but soon proved his incompetence. He modified Calonne's fiscal proposals only in detail and quickly forfeited the confidence of the assembly of notables, which he dismissed on May 25. As the financial crisis deepened, he encountered the vigorous opposition of the *parlement* of Paris to his modified plans for the imposition of a land

tax on the privileged orders. His attempt in May 1788 to deprive the *parlements* of their political powers failed and soon provoked the widespread revolt of the provincial *parlements* and the provincial estates. In June 1788 his demand for an enlarged *don gratuit* from the assembly of the clergy was only partially granted, and this final repulse compelled him, on July 5, 1788, to submit to demands for the summons of the estates-general. His appeal for guidance on the organization of this assembly let loose a war of pamphlets between the supporters of the claims of the third estate for double representation and the representatives of the privileged orders (see FRANCE: History). On Aug. 16, 1788, Loménie de Brienne was compelled to suspend payment from the treasury. Having thus virtually declared national bankruptcy he was persuaded by the queen to resign in favour of Necker. He was then made archbishop of Sens and finally, in Dec. 1788, cardinal.

After the outbreak of the Revolution, he was one of the few French prelates who took the oath to the Civil Constitution of the Clergy in 1790. His former position as a court favourite, however, made him a suspect during the Reign of Terror, and he died in prison at Sens on Feb. 19, 1794. His journal of the assembly of notables of 1787 was edited by P. Chevallier in 1960.

LOMOND, LOCH, the largest and perhaps the most beautiful of Scottish lakes, lies in the north of Stirlingshire and Dumbartonshire, and crosses the Highland edge, so that its scenery is varied from dramatically glaciated mountains in the north to softer, well-wooded hills and islands in the south. Its shape is a long narrow triangle, about 24 mi. north-south and varying in width from 5 mi. at its base in the south to $\frac{1}{2}$ mi. in the north. It lies 23 ft. above mean sea level, and its greatest depth near Inversnaid is 623 ft., a glacial excavation. In the north the loch occupies a narrow glaciated trench among the Dalriadan schists (Ben Vorlich 3,092 ft.) and the grits of Ben Lomond (3,192 ft.). It begins to broaden while still north of the Highland boundary fault line, and the more northerly islands of Inchlonaig, Inchtavannach and Inchconnachan are also of grit, while Inchcailloch and Inchmurrin farther south, actually on the Highland boundary fault, are part of the softer Old Red Sandstone country, though with a core of resistant serpentine. Apart from the catchment area of the Endrick Water-Blane in lowland Stirlingshire, the 160 sq. mi. drained by Loch Lomond seem an anomalously small catchment, and the origin of the loch has long aroused controversy. It appears that parts of three major preglacial river systems draining east or southeast across this area had their watersheds breached to form Loch Lomond and its present catchment area, by powerful Quaternary glaciers from the ice cap of the high-precipitation area of the southwest highlands, giving the very narrow, deep, steep- and straight-sided glacial trough of the upper loch. The loch drains by the short river Leven to enter the Firth of Clyde at Dumbarton. A good road follows the western shore of the loch, parts of the eastern side are accessible by minor roads.

Inchcailloch and Balmaha are mentioned in Sir Walter Scott's *The Lady of the Lake*, Inversnaid in his novel *Rob Roy*. Loch Lomond and the surrounding hills, so near to Glasgow, are naturally a major recreational lung for the city. The loch is used for angling and by various pleasure craft. There are tourist facilities including hotels, camp sites and a youth hostel. The chief lakeside resort villages are Balloch, Ardlui, Inversnaid, Balmaha, Luss, Rowardennan and Tarbet. At Inveruglas is a hydroelectric power station where the penstocks from the Loch Sloy project discharge into Loch Lomond; but the beauty of the countryside remains.

See D. L. Linton and H. A. Molesley, "The Origin of Loch Lomond," *Scot. Geog. Mag.*, 76:26–37 (April 1960). (A. T. A. L.)

LOMONOSOV, MIKHAIL VASILEVICH (1711–1765), Russian poet, grammarian and scientist, the first great Russian linguistic reformer, was born in the village of Mishaninskaya in the Archangel province, on Nov. 19 (new style; 8, old style) 1711, the son of a poor fisherman. He studied in Moscow and St. Petersburg, and spent the years 1736–41 abroad, studying at Marburg university in Germany. In 1741 he became a member of the

Academy of Sciences in St. Petersburg, and in 1745 was appointed professor of chemistry there. His scientific work includes research on the expansion of metals and gases, astronomy, geology, economics and polar exploration. In 1755 he helped to found Moscow university, which is now named after him, and of him Pushkin remarked, "Lomonosov is himself a university." Embittered by his quarrels with fellow academicians, most of them Germans, he took to drink in his last years and died at St. Petersburg on April 15 (N.S.; 4, O.S.), 1765.

Lomonosov's main achievement was literary and his theoretical works on linguistics include the *Kratkoe rukovodstvo k ritorike* (1743; "Short Guide to Rhetoric") and *Rossiskaya grammatika* (1755; "Russian Grammar"). He propounded the theory of three literary styles (high, medium and low) and confirmed the theory of tonic verse, which had already been practised by V. K. Tret'yakovski, and has been the basis of Russian verse ever since.

His creative literary work belongs to the Russian classical movement. It consists mainly of odes, written in a solemn and majestic style to commemorate current events, and also in honour of the reforms of Peter the Great. The odes include *Na vzyatie Khotina* (1739; "On the Capture of Khotin") and *Utrennee razmyshlenie o bozhiem velichestve* (1751; "Morning Reflection on God's Majesty"). In his *Pismo o polze stekla* (1752; "Letter on the Use of Glass") he combines his poetic and scientific interests. His work also includes historical studies, among which is *Drevnyaya rossiskaya istoriya* (1766; "Ancient Russian History") and, in the sphere of art, the revival of mosaics in Russia.

See B. N. Menshutkin, *Russia's Lomonosov*, Chemist, Courtier, Physicist, Poet, trans. by J. E. Thal and E. J. Webster (1952). (R. F. H.)

LOMONOSOV (formerly ORANIENBAUM), a town and summer resort of Leningrad oblast of the Russian Soviet Federated Socialist Republic, U.S.S.R., stands on the southern shore of the Gulf of Finland opposite Kronstadt and 40 km. (25 mi.) W. of Leningrad. Pop. (1959) 27,500. Founded in 1711, it was a favourite summer retreat of the Russian royal family, notably the tsaritsas Elizabeth and Catherine the Great. Notable buildings include the palace of Peter the Great (1714) and the Chinese palace, designed by A. Rinaldi and built in 1762-68. They suffered grave damage in World War II, during the siege of Leningrad, but have been restored. There is a fine park, with pavilions designed by Italian and Russian masters, such as the Katalnaya Gorka. The town was renamed in 1948 after the Russian scientist and man of letters, M. V. Lomonosov. (R. A. F.)

LONDON, JACK (JOHN GRIFFITH LONDON) (1876-1916), U.S. novelist, an enthusiast for social progress who reflected the hopes, conflicts, frustrations and romantic impulses of his period, was born at San Francisco, Calif., on Jan. 12, 1876. He soon moved to Oakland, Calif., where, as he recounts in his autobiographical *John Barleycorn* (1913), he quit school at 14 to escape poverty and gain adventure. In his sloop he explored San Francisco bay, alternately stealing oysters and working for the law, as told in *Tales of the Fish Patrol* (1905); he roamed as far as Japan as a sailor on a sealing cruise; and he saw much of the United States as a member of Kelly's Industrial army (a protest group, born of the panic of 1893, that originated in California and staged a march on Washington) and later as a railroad tramp, riding the rods as described in *The Road* (1907). Observation of depression conditions, fortified by a prison term for vagrancy, turned him in 1894 to Marxian socialism, a doctrine he supported for most of the rest of his life. Rebelling against becoming "a work beast," he crammed high school into one year, took a semester's work at the University of California, and energetically set out to write, supporting himself with odd jobs as narrated in *Martin Eden* (1909).

A winter in the Klondike during the gold rush of 1897 gave London his real start as a writer and supplied him with material for much of his best fiction. Combining his experience with ideas concerning evolution absorbed from Darwin and Spencer, and narrative techniques learned principally from Kipling, he gained a wide audience with his first book, *The Son of the Wolf* (1900). During the remainder of his short life he produced steadily, completing 50 books in 17 years. As his writing rested partly on

reportorial elements, he constantly sought new scenes and experiences; thus, he lived in the London slums to get material for *The People of the Abyss* (1903); he served as a correspondent in the Russo-Japanese War; and he sailed a ketch to the South Pacific, telling of his adventures in *The Cruise of the Snark* (1911) and using the locale in many stories. In 1910 he settled on a large ranch near Glen Ellen, Calif., where he experimented with farming techniques and built his grandiose "Wolf House," which burned before completion. He died at his ranch on Nov. 22, 1916.

Though his writing was uneven, London produced a number of forceful novels and short stories. Besides those mentioned above, the following are outstanding: *The Call of the Wild* (1903), *White Fang* (1906) and *Burning Daylight* (1910), in which he dramatized in turn atavism, adaptability and the appeal of the wilderness; and *The Sea-Wolf* (1904), *The Iron Heel* (1907) and *The Valley of the Moon* (1913), in which he combined adventure with theories about the Nietzschean superman, the future of socialism and the plight of the city worker, respectively.

LONDON, a city of Ontario, Can., the seat of Middlesex county, is 115 mi. S.W. of Toronto, at the forks of the Thames river, 21 mi. N. of Lake Erie and midway between Lakes Ontario and St. Clair. Pop. (1961) 169,569; metropolitan area 181,283. London is a financial, ecclesiastical, medical, educational, military and manufacturing centre; its coat of arms incorporates a locomotive, attesting the continuing importance of transportation in the economy of the city. It is served by all major Canadian railroads and has rail service to Chicago, Ill., and to Detroit, Mich.; there are also excellent highways and a municipal airport.

The name London was first applied to the site when it was chosen, in 1792, for the capital of Upper Canada, but the plan was not acted upon, and there were no buildings until 1826, when the first settlement was made. London was incorporated as a village in 1840, as a town in 1848 and as a city in 1855. This rapid growth was due to its interlake position, its early development as a transportation centre and the excellence of the surrounding land. In 1840 Dundas street, a plank and gravel road, from near Hamilton, was extended to London, and in 1853 the first railroad, the Great Western (now the Canadian National Railways main line), arrived. Thereafter the city grew steadily as a manufacturing, distributing and financial centre. In the 1960s there were over 500 diversified manufacturing industries producing a wide range of goods, including breakfast cereals, biscuits, beer, wine, flour, brass and steel goods, abrasives, diesel locomotives, refrigerators, textiles, hosiery and boxes. There were also printing and lithographing industries. London is the seat of the Anglican diocese of Huron and the Roman Catholic diocese of London. The University of Western Ontario, with its affiliated medical school, is located there. (G. FN.)

LONDON, the capital city of the United Kingdom and the centre of the Commonwealth of Nations. In population it is one of the world's three largest cities (with Tokyo and New York), and it is the nation's largest port and industrial complex as well as its principal financial, commercial, and cultural centre. It lies on both banks of the Thames, near its estuary on the North Sea. Its ancient heart is the City of London, which is situated on the north bank of the Thames at the narrowest crossing and is a county corporate with an area of 677 ac. (about 1 sq.mi. or 2.59 sq.km.) and a resident population (1965 est.) of 4,600. On April 1, 1965, the London Government Act 1963 became law, providing for an administrative area called Greater London that absorbed the former County of London and almost all of Middlesex (the remainder going to Surrey and Hertfordshire) and parts of Surrey, Kent, Essex, and Hertfordshire. Greater London, with an area of 621.8 sq.mi. (1,610 sq.km.) and a population of 7,948,800 (mid-1965 est.), comprised the City (with the Temples) and 32 London boroughs, of which 12 are classified as inner London boroughs and 20 as outer London boroughs (see the section on *Government*, below).

I. PHYSICAL CHARACTERISTICS

1. Geology.—London lies in latitude $51^{\circ} 30' N$, and the prime meridian of longitude passes through the London Borough of Greenwich. The town developed outward from the centre of the London Basin, which is a structural downfold (syncline) comparable to an oval plate disposed with its greater length west-east and slightly down-tilted with the east end submerged under the North Sea. In the rim Chalk is exposed, rising away from the cen-

tre of the basin in gentle dip slopes to heights exceeding 800 ft. (244 m.) above sea level in the Chiltern Hills to the northwest and the North Downs to the south, terminating in steep outward-facing scarp slopes. The Chalk forms a continuous floor to the basin, but is downfolded so that in central London at 86 ft. (26 m.) above sea level it is 157 ft. (48 m.) below the surface.

Above the Chalk the London Basin is filled with great thicknesses of younger sediments. Their distribution is complex, but in general the older formations are toward the edge and the newer toward the centre of the basin. The solid rocks all belong to the Eocene Division of the Tertiary Period. The lowest occur directly above the partially eroded Chalk; called Lower London Tertiaries, they consist of the Thanet Sands, the variable Woolwich Beds, the Reading Beds (sands and clays), and the Blackheath Beds (sands and pebbles). Collectively they are best developed in southeast London, running in a wide crescent from Croydon to Erith with a narrower extension from Erith west to Greenwich. There the Blackheath Beds form extensive sandy plateaus at 200–300 ft. (60–90 m.) terminating in marked south-facing scarps, as along the Cray Valley southeast of Erith. The Reading Beds also outcrop in Harrow and Hillingdon around Pinner and Harefield. Larger in surface outcrop is the mid-Eocene London Clay, a fairly uniform, stiff blue-gray clay, locally over 400 ft. (122 m.) thick. It outcrops widely in the northwest, occupying over four-fifths of the area north of a line Uxbridge–North Acton, and rising northwest to plateaus capped with gravel at 450–500 ft. on the Hertfordshire border, which terminate in a north-facing escarpment overlooking the Vale of St. Albans. Except where capped by the gravels, it forms low, gently undulating ground. The soil is heavy when wet and hard when dry. At the top of the Eocene Series in the London Basin occur the predominantly fine Bagshot Sands, laid down probably under deltaic conditions. Their main mass lies in the southwest of the basin between Aldershot in the west and Orshott in the east, but an important outlier caps Hampstead Heath. The soil is light, dry, and infertile. The sands have been less eroded than the London Clay (because water sinks through them), and so now stand higher (in places over 400 ft. above sea level).

After the deposition of the Eocene rocks, the outer waves of the Alpine earth movements were felt in southeast England, reaching a maximum in the late Oligocene or early Miocene Period and creating the present structural form of the London Basin. Subsequently, important superficial deposits were laid down over the partly eroded Chalk and Eocene rocks. In the Pliocene Period sands were deposited at 550–600 ft. above sea level on the Chalk dip slopes toward the edge of the basin, as between Sandhurst and Warlingham on the North Downs. At the beginning of the Pleistocene Period Pebble Gravels were deposited on London Clay in the northern half of the basin. They form marked plateaus at 450–550 ft. above sea level. They contain chert pebbles (resembling flint) from Surrey, proving that when they were deposited the Thames flowed northward.

During the Pleistocene Period ice advancing from East Angles deposited distinctive chalky boulder clay in hollows eroded by river action in the Pebble Gravel plateaus, notably in the Vale of St. Albans and in a north-south depression from Whetstone to Finchley and Hornsey. This latter represents the southern limit of the Pleistocene glaciation in the British Isles. The Thames and its tributaries were diverted by the ice southward into approximately their present courses, producing a series of flat gravel terraces which they subsequently eroded, so that only fragments remain.

The northernmost and oldest are the so-called gravel trains at 200–370 ft. above sea level round Beaconsfield and Chalfont St. Giles, Buckinghamshire. Southward the most important terraces are: the Black Park Terrace, at about 110 ft. above sea level; Wimbledon Common; and the Boyn Hill Terrace, about 100 ft. which appears north of the Thames at Farnham Royal, Surrey; Poles, Hillingdon, Isleworth, Ealing, Islington, Highbury, Walthamstead, Barkingside, and Fairlop Plain. South of the Thames is seen at Virginia Water and Walton Common, Richmond, Twickenham Common, and Lewisham. The Taplow Terrace, about 50 ft. above sea level, extends widely and almost continuously north-

the river through Slough, Hayes, Southall, Hounslow, Acton, Shepherd's Bush, Hyde Park, Holborn, the City, Stepney, Clapton, Tottenham, Edmonton, Enfield, Wanstead Flats, Ilford, and Becontree Heath; south of the river it is developed at Byfleet, New Malden, Merton, Mitcham, Beddington, and Crayford. The Flood Plain Terrace (about 25 ft.) is seen at Datchett, Egham, Molesey, Teddington, Kew, Fulham, Battersea, Chelsea, Southwark, Limehouse, West Ham, East Ham, Barking, and Dagenham. The marked slope down from the Boyn Hill to the Taplow Terrace is seen in Pentonville Road east of King's Cross Station; that from the Taplow to the Flood Plain Terrace in Exhibition Road (South Kensington) and St. James's Street. Below the Flood Plain Terrace is the alluvium (5–15 ft. above sea level) deposited by the Thames in slack water at high tides from Neolithic to early historic times, consisting of dark gray clay, sometimes weathered to brown at the top, containing impersistent bands of peat, shelly marl, and sand. Finally, central London has up to 20 ft. of "made ground" accumulated in historic time.

The distribution of these deposits has had an important influence on human settlement and land use. The City of London was founded on twin hills of Taplow Gravel, opposite a point on the south bank of the Thames where a tongue of flood-plain gravel approaches the river, reducing to a minimum the passage across the marshy alluvium. The river crossing thus created became the site of the first London Bridge. The gravel provided a dry site and a water supply for the city. London grew as a trading centre partly because of the easy route along the south bank of the river below London Bridge, via the belt of well-drained Lower London Tertiaries and Chalk, to the English Channel ports. In Saxon times many agricultural villages, later to become suburbs of London, developed on the dry sites afforded by terrace gravels (Islington and Clapham on Boyn Hill gravels; Paddington, Hoxton, and Dalston on Taplow Gravels; Newington, Fulham, and Stepney on Flood Plain Gravels). The gravel soils, containing silt admixture, were fertile and easy to work.

Below the terraces the damp alluvium was generally avoided for building until recent times. The London Clay also was damp, and drinking water was difficult to obtain before the advent of modern piping systems; so it remained relatively unsettled. It could be cultivated from dry-point sites for cereals, though its soils are badly drained and lack lime; grass growing is perhaps its logical use. For centuries the clay was made into bricks for London's houses. Since 1900 the tide of speculative building has almost completely covered it, though it is not good building land because of a tendency to crack in dry weather and to creep in wet weather.

The coarse gravels and sands of the Pebble Gravels, Bagshot Sands, and Blackheath Beds are dry, poor in plant foods, and infertile. They were often used as common grazing land, and remained as commons after building had advanced round them (Blackheath, Bostall Heath, and Hayes, Keston, and Chislehurst commons on Blackheath Beds; Wimbledon Common, Bushey Heath, Epping Forest on Pebble and Plateau Gravels; Esher Common and Hampstead Heath on Bagshot Sands).

2. The River.—The Thames flows west-east through the London Basin, having entered it by the Goring Gap, northwest of Reading, Berkshire. Its general line is slightly south of the centre of the syncline and throughout its recent history it has continued to shift southward; it bites at the foot of the Chalk dip slope below Dartford. It has well-developed meanders and an extensive alluvial flood plain. Embanking of the river took place mainly between the 12th and 14th centuries, reclaiming 42½ sq. mi. (110 sq. km.) of marsh between London Bridge and the sea. This area was mainly too damp for building but was used extensively in the 19th century for dock construction on the Rotherhithe and Deptford marshes and on the Isle of Dogs.

In early times the tidal limit of the Thames was probably London Bridge, a fact doubtless critical in the choice of the site of the city; subsequent embanking has caused the tide to advance up to Teddington Weir, about 19 mi. (31 km.) upriver. The mean tidal range reaches a maximum just below London Bridge. The navigable channel below London Bridge is the result of dredging in

recent centuries. It is 14 ft. immediately below London Bridge, 16 ft. below Wapping, 20 ft. below Greenland Dock (Rotherhithe), and 27 ft. below King George V Dock (North Woolwich).

Four northern tributaries of the Thames flowed through what is now central London, but have been lost in that none reaches the river above ground. The Walbrook flowed through the centre of Roman London and was used by shipping; its valley is now marked by a slight dip in Cannon Street near the station. The Fleet rose in Hampstead and Highgate ponds and flowed by King's Cross to join the Thames at Blackfriars; it gave its name to Fleet Street. The Tyburn rose near Swiss Cottage and flowed by Marylebone and Green Park to join the Thames just west of Vauxhall Bridge; its valley is marked by dips in Oxford Street near Bond Street tube station and in Piccadilly near Half Moon Street. The Westbourne, Kilburn, or Bayswater rose west of Hampstead and flowed southward to join the Thames near Ebury Bridge; part of it now forms the Serpentine, a lake in Hyde Park, and it is carried in an iron pipe over Sloane Square Station; the name Knightsbridge recalls a former crossing point.

Outside central London the Thames tributaries still run mainly above ground. Most important on the north bank are the lower Colne, running southward from Rickmansworth to Staines in an alluvial valley about ¼ mi. wide; the Brent, flowing from Edgware and Totteridge (where it is called Dollis Brook) through Hendon and Brent Reservoir (Welsh Harp) to Brentford; and the lower Lee or Lea which flows south from Ware in an alluvial valley about 1 mi. (1.6 km.) wide through Ponder's End and across Hackney Marshes to join the Thames below Poplar. On the south bank the Wandle rises near Croydon and joins the Thames at Wandsworth. Where these streams have wide alluvial flood plains they have impeded communication and settlement; in some cases they have been developed in modern times for industry (the Lee and Wandle valleys) and arterial roads (the North Circular Road in the Brent Valley). (See also THAMES.)

3. Climate.—The climate of the London Basin is typical of that of the eastern margin of the British Isles. Rainfall is basically cyclonic, influenced in its local distribution by relief; it ranges from over 32 in. (813 mm.) annually on the crest of the North Downs to under 25 in. (635 mm.) on Thames-side below Dagenham, which is part of the driest region in Britain. Summer rainfall is mainly convectional and in the form of a few heavy falls. Generally there is an April minimum and an October maximum with a secondary minimum in September and a secondary maximum in August. The rainfall is irregular from year to year with extremes of 70–130% of the average.

Temperatures in the area vary little (on the average by 11.7° to 13.1° C or 51° to 55° F). Summer and winter averages are higher in London's built-up area because of heat retention by buildings, smoke cover, and artificial heating. Thus the mean January temperature at St. James's Park is 5.0° C (41° F) and the mean July temperature 18.2° C (65° F), while the corresponding figures for Kew Observatory (Surrey) are 4.4° C (40° F) and 17.6° C (64° F). St. James's Park has 23.4 in. (595 mm.) of rain a year; Kew 23.95 in. (608 mm.). Sunshine is reduced by fog in the central area, especially in mid-winter; but there has been a spectacular reduction in the incidence of "pea-souper" fogs ("London particulars") and even smog is now rare. This reduction is chiefly attributable to the replacement of coal fires by gas, electricity, and oil and the establishment of smokeless zones under the Clean Air Act 1956.

(P. G. H.)

4. Vegetation and Animal Life.—London is of special interest to naturalists for the plants and animals which thrive there in close association with man. More detailed records covering a longer period are available for London than for any other large city, and they are kept up to date by the London Natural History Society.

In the centre wild plants are found in the parks, squares, and private gardens, on building sites, railway banks, neglected gutters, and broken walls. Many of the commonest have wind-borne fruits so that they quickly colonize any soil available. The most conspicuous of these are Oxford ragwort, which is native to the central Mediterranean, and rosebay willow-herb, which has spread

rapidly since World War II. Bracken grows freely from wind-borne spores, though this form of reproduction appears to be rare in the country. A shrub, *Buddleja davidii*, introduced as a garden plant from China, and Canadian fleabane, a native of North America, are also common. These were the five most abundant plants growing on bombed sites during and after World War II, when 269 species were found in the "square mile" of the City.

In the suburbs the number of species is much greater. Wimbledon, Mitcham, and Barnes commons, Hampstead Heath, and Epping Forest have a good representation of wild plants. Within 20 mi. (32 km.) of St. Paul's Cathedral, a wide range of habitats occurs, including chalk grassland, woods, heaths, Thames meadows and marshes, and London Clay fields and commons, and there 1,835 species of flowering plants and ferns, 221 mosses, and 68 liverworts have been recorded since 1900.

London has given its name to several plants. London rocket (*Sisymbrium irio*) was first recorded in 1666, the year of the Great Fire, and after long absence reappeared in 1947. London ragwort (*Senecio x londonensis*), a hybrid between Oxford ragwort and viscid groundsel, was common from 1943 to 1950 when the two parents grew together on bombed sites. London plane (*Platanus x hybrida*) thrives in London and is the tree most commonly planted in the streets. London Pride (*Saxifraga umbrosa*) was so-called because it was introduced by a nurseryman named London.

Four kinds of birds have learned to live in great numbers in close association with man. Feral domestic pigeons (*Columba livia*) have been a feature of London birdlife for at least 600 years and are familiar to visitors to Trafalgar Square, St. Paul's Cathedral, Victoria Station, etc. They depend mainly on food supplied by human beings. House sparrows abound in central London, though their numbers seem to have decreased since automobiles replaced horse traffic, thereby removing their main source of food supply—oats spilled from nose bags and near stables. Black-headed gulls have been regular winter visitors since 1895 and are seen in large numbers by the Thames and elsewhere. Since about 1925 some nonbreeding gulls have remained throughout the summer, and a breeding colony was established near London Airport in 1941–42. On winter evenings long flights of gulls returning to their roosts on reservoirs in the Thames and Lea valleys are a familiar sight, and the number roosting in midwinter has been estimated at 85,000–100,000.

Immense numbers of starlings roost on buildings in central London, especially round Trafalgar Square, and their spectacular massed flights at dusk from the suburbs, where they spend the day feeding, and their noisy arrival at the roosts, attract much attention; the numbers are increased by immigrants from Europe in the winter. A much rarer bird is the black redstart, a summer visitor which has bred in or near London in every year since 1926. In 1942 there was a sudden increase in numbers when large bombed areas provided exceptionally favourable temporary habitats. The mute swans (*Cygnus olor*) on the Thames are the property of the crown and are marked by the Vintners' and Dyers' (Livery) companies, which have a royalty. An ancient ceremony known as "swan-upping" takes place each July to mark the birds and then congregations of 100 or more may sometimes be seen on the Thames in central London. The ravens at the Tower of London are semidomesticated birds introduced from Wales.

In inner London 160 species of birds are recorded and 37 have bred. The royal parks provide the best opportunities for their study. St. James's Park and Kew Gardens have good collections of waterfowl. Within 20 mi. of St. Paul's 245 species have been recorded since 1900 in a wide range of habitats that include reservoirs, gravel pits, sewage farms, woods, heaths, and marshlands. Of these species, 100 are believed to nest annually.

The brown rat is a great pest, and the black rat is found in the upper parts of buildings over a large area, including the West End. London is one of the few British cities where black rats are found away from the seaport area. The house mouse is common, hedgehogs are frequent in the suburbs, and several species of bats occur.

Butterflies are often seen, and some species, such as the migrant red admiral, congregate around the flowers of buddleja and michaelmas daisies. Many moths occur in central London, where

the lime hawk, eyed hawk, and poplar hawk (*Loathoe populi*) are among the larger species. The trend toward melanism (q.v.) is less general in moths in London than in other industrial cities but is shown in a few species including the peppered moth, in which the black form is dominant. (J. E. Lo.)

II. POPULATION

Aspects of population growth from earliest times are discussed in *History* below.

Within the Greater London conurbation a decline in population has occurred in the City of London since 1851, in inner London (comprising after 1965 the inner London boroughs covering approximately the area of the former County of London) since 1901, and in suburban or outer London (mainly the outer London boroughs which developed as a suburban ring) since 1951. Encircling

TABLE I.—Population of London

Year	City of London	Inner London*	Outer London†	Greater London conurbation‡
1801	128,269	959,310	157,980	1,117,290
1851	127,869	2,363,341	321,707	2,688,048
1901	26,923	4,846,267	2,050,002	6,586,269
1951	5,324	3,347,936	5,000,041	8,348,023
1961	4,767	3,200,484	4,976,788	8,171,902
Mid-1965 est.	4,600	3,160,380	4,783,820	7,948,800

*Comprising the County of London after 1888 and the inner London boroughs after 1965. †After 1965 the outer London boroughs. ‡Area reduced in 1965 when it became coterminous with that of the Greater London Council plus the City of London.

the conurbation area (coterminous with the Greater London Council area plus the City after 1965) is a broad fringe up to 30 mi. wide of almost continuous population increase (more than 1,000,000 since 1951) which embraces satellite towns beyond the Green Belt areas (lands held for public open space to restrict further sprawl of built-up areas) and extends along every major road and rail route from London. The entire London and South-Eastern Region had a population of more than 12,500,000 in the late 1960s, more than one-third of which was outside the Greater London conurbation. (P. G. H.)

III. HISTORY

A. ROMAN PERIOD

The history of London begins effectively with the Roman period, though finds of various pre-Roman dates are sufficient to indicate that as elsewhere along the Thames the area was probably occupied by a succession of small prehistoric communities. The Roman settlement (Londinium) no doubt came into existence with the first successes of the Claudian conquest in A.D. 43, and from the beginning a bridge over the Thames must have played an important part. It is generally accepted that its siting, rather to the east of the existing London Bridge, was probably governed by tidal conditions, which in their turn were affected by the fact that the river was at least 15 ft. lower in relation to the land in Roman times than it is today. The subsequent importance of London was based on the development of the port and on the control of the road system. As a bridgehead settlement the city seems to have originated on the eastern hill (Cornhill). There was the basilica, and the street that leads from the bridge is still preserved in the line of the modern Gracechurch Street. The extent of the first open city can be determined by tracing the distribution of the fires set by Boudicca's (Boadicea's) Icenian tribesmen during their revolt against the Romans (A.D. 60) when Londinium was sacked. The settlement had begun to spread beyond the Walbrook Stream to the western hill (where St. Paul's was later built), and the locality seems to have been well occupied by the late 1st century.

Some replanning appears to have followed the Boudiccan episode; the rebuilt basilica, for instance, was much larger than the old one. The next outstanding event was the building of the Cripplegate Fort on the northwestern fringe of the city. About 11 ac. (4.5 ha.) in extent and built c. A.D. 100, the fort must have acted as a military depot attached to the port. But the city was still unwallled and remained so throughout the 2nd century A.D. In the meantime there is archaeological evidence for further wide spread damage by fire in the 120s.

Aerial view of the Tower of London on the north bank of the river Thames. In the centre is the White tower, begun for William the Conqueror by Gundulf, bishop of Rochester, about 1078

Westminster abbey seen from the southwest. Altered many times since its founding in 1050 by Edward the Confessor, the church nonetheless remains one of the finest examples of medieval architecture in England. The west towers, shown here, were completed in 1745

The clock tower, at the north end of the Houses of Parliament, containing Big Ben. A light in the tower at night indicates that the House of Commons is sitting

New Zealand house, Haymarket, 1959-63. Postwar construction of tall buildings, such as this one, greatly altered the London skyline

River Thames as seen from the Shell building on the South bank. Westminster bridge is to the right. In the right background is the Victoria tower of the Houses of Parliament. Lambeth bridge and the Vickers building, Millbank, are in the centre background

TRADITIONAL LONDON

The city wall was built to enclose the occupied area at the earliest toward the end of the 2nd century. The fort was incorporated in the new defensive system and, with its north and west walls then looking outward as part of the city wall, formed the Aldersgate reentrant, thus giving the city two northwestern angles on that side. The later history of the fort and its relationship with the city are not known, though it seems probable that the fort continued in existence into late Roman times.

Throughout the late 1st and 2nd century the growth of the city seems to have continued, though in the absence of written record and limited opportunities of archaeological exploration detailed knowledge is restricted. The best-known building is the basilica, an aisled hall 500 ft. (152 m.) long with the forum attached to its south side. Stone buildings were widely distributed but are represented only by fragments of walls and mosaic floors, with no complete plans. The exceptions to this are the temple of Mithra adjoining Walbrook, a bath building on the north side of Cheapside, and the fragments of a second under the Coal Exchange in Thames Street. A large proportion of the Roman buildings were of timber or "cob," with thatched roofs, their materials reflecting the absence of building stone near London. The street plan is very inadequately known, and post-World War II discoveries have done little to confirm earlier theories. Cheapside and Cannon Street mark original east-west Roman streets, and even apart from the clues provided by the known Roman gates it seems likely that the medieval street plan to some extent reflected that of the Roman city.

Though little evidence from the ground can be brought to bear on the later periods, London during the 3rd century evidently retained its prosperity and enhanced its importance. About A.D. 286 the usurper Marcus Aurelius Carausius established a mint there. In 296 the struggle between Constantius I and Allectus involved the city; the famous gold medallion found at Arras, France, in 1922 celebrates its relief by Constantius from the threat of sacking by the defeated troops of Allectus. According to a 6th-7th-century codex London sent a bishop to the Synod of Arles in 314 and was then and later a centre of early Christianity. During the 4th century also it was accorded the title of Augusta when it figured in the troubles with the Picts and Scots and other barbarians who were defeated by Theodosius I. Archaeologically the disturbed conditions of the late 3rd and 4th centuries are reflected in some of the semicircular bastions which in London as elsewhere were late additions to the Roman wall. Throughout the 4th century London appears to have continued as the financial and administrative centre of the province, but little is known about its physical character of that time.

Some of the late bastions were built of materials derived from tombs and other monuments—a reminder that activity was not confined to the area of the walled city. Cemeteries existed in Whitechapel, Bishopsgate, Fleet Street, and elsewhere. There were Roman buildings beyond the River Fleet to the west, and there were settlements also at Southwark and near the river crossing at Westminster, where burials also have been found. There must have been other minor habitation sites, farms and so on, in the surrounding country; their slight remains would escape recognition in the built-up area of modern London. (See also *BRITAIN*.)

(W. F. G.)

B. ANGLO-SAXON PERIOD

After the departure of the Roman legions in the early part of the 5th century A.D., little or nothing is known of what happened in London for the next 150 or 200 years. Some have suggested that it never fell to the Anglo-Saxon invaders but remained an independent city whose inhabitants preserved the Roman way of life throughout the centuries; others have concluded that it crumbled to ruin, haunted only by a few refugees. Probably neither of these conjectures is exact. What does seem clear is that during the 4th and early 5th centuries the importance of London was much diminished. The large Roman city of Londinium had owed its existence to trade and particularly to foreign trade; this was adversely affected by turbulent and unsettled conditions on the continent and so London grew less powerful.

By the end of the Roman occupation, however, many of London's buildings were of stone and the city was surrounded by a great stone wall. Such a wall protected the remnants of the population who could still make a living there, and no doubt it afforded a refuge for those Britons who fled to London after their defeat by the Saxon Hengist at the battle of Crecgan Ford (possibly at Crayford, Kent) in A.D. 457. Moreover, the site of Londinium never became so overgrown and ruinous that the lines of its main roads and the position of its gates were lost. The east-west roads of Cheapside and Cannon Street have been proved to be the medieval successors of Roman roads in their general alignment, and the gateways at Aldgate, Bishopsgate, Cripplegate, Aldersgate, Newgate, and Ludgate are demonstrably of Roman origin.

Just how London came into the possession of the Saxons is not known, for no chronicler mentions its capture. Few finds of 5th- and 6th-century date have been made in the London area, but it must be remembered that, by comparison with their Roman predecessors, the Saxons had few personal possessions, so a mere numerical comparison between finds of late Roman and early Saxon date is not significant. What is notable, however, is that the nearest Saxon cemetery of this date, so far discovered, is at Greenwich, about 5 mi. (8 km.) away, while others at Hanwell, Mitcham, Beddington, and Croydon are about 10 mi. away. While it is possible that an early Saxon cemetery nearer to the city may await discovery, the available evidence so far suggests that there was at first little contact between the Londoners and the new arrivals. A buckle plate of 5th-century date, now in the British Museum, found at Smithfield, decorated in chip carving technique, and a cruciform brooch from Tower Street are the earliest finds of the Saxon period from London. In the London Museum are about half a dozen objects which can be dated with some certainty to the late 5th or early 6th century, but beyond these, few, if any, objects belonging to the first 150 years of the Anglo-Saxon period have been found.

After the arrival of St. Augustine's mission (597), the importance of London increased. Aethelberht (d. 616), king of Kent, founded St. Paul's Cathedral and Mellitus was installed as bishop (604). Pope Gregory I, who had sent Augustine, appears to have intended that London rather than Canterbury should become the southern metropolitan see; but this aim was never realized. It would be possible to argue from Pope Gregory's plan that London had again become an important city by the beginning of the 7th century; but it is also possible that the pope was simply following the Roman administrative pattern which had long ceased to have any actual significance.

Though Mellitus was soon driven out of his bishopric by the pagan revival that followed the death of Aethelberht, London had come to life again and many objects have been found which date from the next century or so. The rising importance of the port of London is also clearly shown in various literary sources; Bede (d. 735) described London as the mart of many people coming by land and sea. London is not, however, mentioned again in Anglo-Saxon sources until the time of Alfred (d. 899) and the wars with the Danes. The Danish Army wintered in the city in 871-872 and a garrison may have remained there for some years after that date, using London as a base rather than a capital. In 886 Alfred himself occupied London, and his first biographer, Asser, tells that he made considerable repairs to the defenses. A bronze pendant with animal ornament, found in one of the bastions of the city wall, which some archaeologists would assign to the 9th century, may be associated with this work. London was entrusted by Alfred to his son-in-law Aethelred, ealdorman of Mercia, and it became an outpost of resistance against the Danes.

The archaeological evidence for the history of London in the later Anglo-Saxon period is again rather sparse. There is no lack of evidence to demonstrate the city's trading importance, for it was obviously by then an important commercial centre with a large population. Imported pottery from the Rhineland has been found which dates from this period; such imports appear to have continued until after the Norman Conquest, showing that, far from causing a break, it stimulated trade. The stock-in-trade of a working jeweler, found in Cheapside, provides further evidence of con-

temporary prosperity. In 1962 evidence of a great Saxon hall of the 8th or 9th century was discovered beneath the remains of a Tudor palace under 10 Downing Street. It contained domestic objects including some Ipswich ware and German pottery.

An indication of, at any rate, one of the types of domestic building of this period may be seen in the remains of an 11th-century hut of Saxo-Norman style excavated in 1956 by W. F. Grimes on the site of the Financial Times Building, close to St. Paul's Cathedral. This was a wooden hut about 10 ft. (3 m.) square; its walls consisted of a number of uprights made of tree trunks split in halves longitudinally, to which were fastened horizontal planking. Two city churches have, so far, been proved to have Saxon foundations. At All Hallows' by the Tower, bomb damage during World War II revealed an early Saxon arch at the west end of the south wall of the nave which may have given access to the *porticus* of the early church. The style of masonry suggests that this could have been built in the late 7th century. From the ruins of the church came fragments of a late Saxon preaching cross and from the medieval blocking of the Saxon archway came a fragment of a Viking tombstone which must have been almost identical with that found in St. Paul's Churchyard in 1852 and now in Guildhall Museum. It bears a runic inscription which may be translated "Kona and Tuki set this stone up" and is generally recognized as the masterpiece of 11th-century art in Britain. It has been suggested that Tuki might be the Tuki (Tokig) who was a minister of Canute (d. 1035). The other city church with proved Saxon origins is St. Bride's in Fleet Street on the western edge of the City. There Grimes uncovered the foundations of the first church, which, dating from the mid-11th century, had already replaced its original east end by an apse. These remains have been preserved and can be seen below the present St. Bride's Church.

London was the largest town in 11th-century England, and it was developing in resources and in political consciousness. Some estimate of its trading importance can be gathered from the fact that more than 20 moneyers are known to have been minting simultaneously after 1042, more than are recorded for any other borough.

The growth of Westminster with its palace and monastery under Canute and Edward the Confessor fixed the pattern for London's future growth in the dual capacity of centre of commerce and seat of government, the City functioning for one, Westminster as the seat of the royal court for the other. But in the 11th century London was still far from having become the national capital, since the king's court, the centre of government, was still completely mobile; but the fact that the city had been the centre of organized resistance gave the citizens some sense of importance and laid the foundations of their claim to the right to choose the king for England. The government of the borough itself was more complex than that of the provincial towns. Justice was administered through a series of courts meeting for three sessions a year. These folkmoets were responsible for order in the city and all citizens were expected to attend. In addition, the hustings met frequently for the transaction of civil business and probably originated as a court to settle pleas in which Danes and English were involved. By the time of the Conquest dealings between English and foreign traders are known to have been transacted there.

After their defeat at the Battle of Hastings (October 1066), the English leaders seemed to think that London could be held while another army was raised. William the Conqueror sensed this and began an advance on the city. No resistance was offered to him by the defenders under Edgar (the Aetheling) until he came to the south end of London Bridge, where he beat back their sortie. He then began a wide encircling movement, through Surrey, northern Hampshire, and Berkshire; this obviously alarmed Edgar's party by its speed and menace, and at Wallingford on the Thames William received an oath of fealty from Archbishop Stigand. His conclusive meeting with the English leaders took place at Berkhamsted, where he received oaths of fealty from Edgar himself and the most prominent men in London. It is not clear whether further fighting occurred before the city itself was surrendered, but it is obvious that most Londoners were eager for William to take control of the situation and to this end he was ordained king in

Westminster Abbey on Christmas Day, 1066. Perhaps the most definite clue to the status of London and its citizens in late Saxon times is to be found in the charter which William granted to the city almost immediately. This simply promised that the citizens could enjoy the same laws as in King Edward's time, that every child should be his father's heir after his father's day, and that the king would suffer no man to do them wrong.

C. MEDIEVAL LONDON

By about 1180 when William Fitzstephen, biographer of Thomas Becket, wrote a famous description of London, it had become a city of consequence and the effective capital. Boasting 13 monasteries and 126 churches, it was dominated by William the Conqueror's White Tower, and Montfichet and Baynard's castles. After the fire which about 1136 destroyed many of the wooden thatched houses and St. Paul's itself, many richer citizens rebuilt their houses with stone and tiles. The streets were paved and at any rate partially cleansed by open sewers and conduits. London Bridge was still wooden; the stone replacement begun in 1176 took about 33 years to complete. The City was spreading beyond its walls; William II's new palace at Westminster was completed by 1099, and the space between there and the City already contained a scattering of buildings. The mansions of the great were imposing, and the well-to-do had pleasantly laid-out houses, backed by gardens and trees. The city boasted a public cookshop.

London had its share of amusements. At Smoothfield (Smithfield), where horse sales were held, races also took place. Bull- and bearbaiting were popular, as was cockfighting; wrestling and archery were practised and the citizens had retained from pre-Conquest times the right of hunting in the Chilterns.

The administration of justice continued much as in late Anglo-Saxon times, the sheriff presiding thrice yearly at the folkmoet, the hustings meeting weekly at the Guildhall, while in Henry I's time the City was divided into wards for which various aldermen presided at the wardmoets, the London parallel of the provincial hundred courts. There also existed various private sokes or liberties, areas within which individuals or corporations, lay or religious, had been granted special rights and privileges. A charter of Henry I granted to the citizens important privileges, such as exemption from certain tolls and taxes and from the cumbersome procedure of trial by battle in civil disputes. They also had the right to account for the farm (rent) of Middlesex (assessed at £500), direct to the exchequer, and could appoint their own justiciar. Although the citizens formed a short-lived commune as early as 1141 to protect their rights, they were not able steadily to maintain them since Stephen and then Matilda appointed Geoffrey de Mandeville, earl of Essex and hereditary constable of the Tower, their "mortal foe," as sheriff and justiciar, and the farm, which had been reduced, was raised again by Henry II to £500.

London's trade was rapidly expanding and the wharves were always loaded with goods, some of which came from as far away as Constantinople. There had been in London a flourishing Norse colony, which accounts for the dedication to St. Olaf (Olave) of six City churches; but already the Germans, especially the merchants of Cologne, were supplanting the Danes as the largest foreign colony. The London weavers were particularly well-organized, and guilds, such as that of the bakers, which existed in the reign of Henry II, were rapidly developing; but 18 "adulterine" guilds were swept away in 1180, including that of the goldsmiths.

The disputed succession which had followed the death of Henry I in December 1135 enabled the Londoners to exercise their claim to elect the king of England. They chose Stephen, who was crowned at Westminster within three weeks. After his capture at Lincoln (1141) they temporarily supported Matilda but were rapidly alienated by her temper and arbitrary demands for a tallage (or tax) and expelled her from the city after a very short sojourn there. When her army besieged Winchester soon afterward, London sent nearly 1,000 men-at-arms to its relief.

(N. C. C.)

At the accession of Richard I in 1189 London emerged from a period of repression by Henry II. In 1191 the City obtained recognition of a commune, a sworn association of citizens claim-

ing to rule as a sovereign body, with a chief officer called mayor. The mayor, elected annually after 1215, represented the community and was the king's executive officer; he was soon assisted by an advisory body of aldermen, who from late Saxon times had been the leaders of the wards (24 in number by 1206 and 25 after 1394) into which the City was divided. In theory, the men of the wards elected the aldermen, and the whole community elected the mayor and sheriffs and approved legislation. In practice, the choice of officers and the direction of policy were increasingly performed by a closed oligarchy. By bargaining shares of its wealth with impecunious kings, primarily with John, London freed itself from royal officials; after 1215 it could again elect its sheriffs and account for royal revenues direct to the exchequer. Though kings sometimes withdrew its privileges, as did Henry III from 1265 to 1270 and Edward I from 1285 to 1298, they usually found coercion less expedient than compromise in their dealings with London, and they regularly sought advice from mayors or prominent citizens. The City thus continued to consolidate its autonomy, prestige, and commercial advantages.

Preoccupied with trade, London had little wish to meddle in politics. Yet the gradual establishment of government departments, courts and colleges of law, and meetings of Parliament at Westminster had by the mid-14th century identified London as the political and administrative capital. The City was inevitably caught up in national affairs—in the deposition of Edward II in 1327 and of Richard II in 1399, for example, and in the Peasants' Revolt of 1381 and Jack Cade's rebellion of 1450. Usually the citizens supported strong, orderly government. In the dynastic conflicts of the 15th century the City's chief concern was the maintenance of order within the walls, for experience had shown that national unrest tended to provoke subversion in the City.

Mutual rivalries within the trading community and between the poorer craftsmen and traders and the governing clique led to conflicts in the 14th century. By 1377 London had at least 50 craft guilds (*i.e.*, the livery companies; *q.v.*) and 111 by 1400. The most powerful were associations of traders such as the mercers, grocers, and drapers—wholesalers with far-reaching interests outside London. It was their influence that prevented the smaller, more radical guilds from breaking the civic oligarchy in 1319 and in the 1380s. Power thus remained in the hands of the richest merchant class in the 15th century, and with power, the heavy responsibility of supervising almost every aspect of urban and commercial life.

Despite its turbulence and suspicion of strangers, London attracted men from far and wide. Some, like Richard Whittington (d. 1423) from Gloucestershire, achieved both fame and fortune. Before his day much of London's trade had also been handled by resident merchants from Gascony, Flanders, north Italy, and north Germany. The Steelyard, the headquarters of the German merchants until 1598, covered 3 ac. (1.2 ha.) beside the Thames.

Crowded with wharves, warehouses, and about 50 steep lanes, the extensive waterfront proclaimed London's dependence on the river for its everyday needs and its domination of English commercial life. It captured a major share of the wool and then of the cloth trade, sapped the vitality of ports like Southampton, and monopolized the activities of the Merchant Adventurers, who specialized in overseas trade. With its diversified markets and crafts, the city could survive occasional recessions. Archaeolog-

ical and historical evidence attest the growing material comfort of the medieval Londoner. His timbered workshop dwelling was nonetheless cramped and squalid. Only the richest merchants like

the draper Sir John de Pulteney (d. 1349), with his house at Cold Harbour in Dowgate and that called after him Poultney's Inn in Candlewick (now Cannon) Street, could emulate the mansions of noblemen.

Apart from such residences, the fantastic beauty of the bridge, the Guildhall (built *c.* 1411-40), the City was with its seven gates, and the Royal Tower, the chief architectural ornaments of London in the later Middle Ages were St. Paul's Cathedral, whose choir had been greatly extended in the 13th century, and the 23 important religious houses and many smaller establishments. Its parish churches were more numerous than splendid, since they served a population of 35,000 (in 1377) or less. Most of the monasteries had been founded in the 12th century. Others followed, like the Benedictine nunnery of St. Helen, Bishopsgate (1205-15), the Carthusians' Charterhouse (1371), and the Cistercian abbey of St. Mary Graces (1350). Foundations of this period, however, were usually small and dedicated to some specific purpose, like Bethlehem (Bedlam) Hospital (1247) for the insane. In the 1220s the Dominican and Franciscan friars arrived at London; such was their popularity that they, and to a lesser degree the Crutched, Austin, and Carmelite friars who followed them, were able to build on a grand scale—the Franciscans off Newgate Street and the Dominicans in the district still called Blackfriars. Since there were also many chantry priests in London, and bishops and abbots had more than 30 town houses in the city, the church impinged at every turn on London's life. A priory like Holy Trinity, sometimes called Christchurch, Aldgate, owned properties in 60 parishes; yet at least half the large monastic precincts were liberties, immune from civic interference and responsibilities.

D. TUDOR AND EARLY STUART LONDON

Henry VIII began the dissolution of the monasteries and the confiscation of their properties by the suppression (1532) of Holy Trinity, Aldgate. The civic authorities expressed no disapproval,

except when the king also took over the liberties, and within ten years all the monasteries had fallen to the crown. Great changes in landownership resulted, many monasteries and episcopal palaces being granted or sold to courtiers whom the king wanted to reward or enrich. Others provided the materials for new buildings like Protector Somerset's palace in the Strand, begun in 1547. Some were used as storehouses, workshops, or the halls of city companies. Ten churches, or parts of them, became parochial and thus survived. But most of the monastic sites were soon covered with new houses and tenements.

This intensive use of the newly available land was necessitated by a startling growth of population, resulting from immigration and an enormous expansion of trade. The Thames became more than ever the centre of the Londoners' world. Under Henry VII London's Merchant Adventurers gained a monopoly of the main outlet of English trade through Antwerp. Exports of cloth, the very basis of the economy, were doubled under Henry VIII. After the Netherlands market collapsed London looked farther afield and supported the maritime adventures that led to the foundation of the Muscovy Company (1555), the Turkey (afterward the Levant) Company (1581), the East India Company (1600), and several others. The building of the first true business centre, Sir Thomas Gresham's Royal Exchange (1566-67) in Cornhill, was a mark of the new prosperity and enterprise. Successful London businessmen were investing in country estates. New industries, among them silk weaving, majolica pottery, and glass, were

established, often beyond the city boundaries and the restrictive influence of its companies. Theatres also, despised by the City Corporation, were set beyond its jurisdiction in Moorfields and on Bankside. A new spirit of materialism brought church building to a halt, turned the nave of St. Paul's into a fashionable resort and marketplace and its courtyard into London's book centre, and found eloquent and violent expression in the playhouse and in the bear garden on Bankside.

Alongside the luxury found in Elizabethan London, much poverty and distress also existed, no longer mitigated by monastic charity. By 1545 the Charterhouse (*q.v.*) had become the mansion of Sir Edward (afterward Baron) North; its conversion into a hospital and school by Thomas Sutton in 1611 was typical of many acts of private charity which endowed schools, hospitals, and almshouses. The City authorities also tackled poverty and unemployment by introducing assessments for poor relief in 1547, stigmatising the foundation or reconstitution (1545-53) of the five royal hospitals (St. Bartholomew's, Christ's, Bethlehem, St. Thomas's, and Bridewell), and providing grain in times of scarcity. The growth of London's population and of unregulated suburbs gave constant alarm to the government, who feared famine, disorder, and the ruin of the provinces, for London controlled 80% of the country's trade while other towns languished. But repeated acts after 1580 failed to stem the city's growth. In 1605, by filling up monastic sites and garden land and by subdividing tenements, 75,000 people had been housed within the walls and a further

150,000 lived in suburbs; the population had roughly trebled since 1530. Southwark was growing; it had become the 26th City ward, under the name of Bridge Without, in 1550.

But the main developments were taking place on the west, where houses began to appear in Lincoln's Inn Fields and Covent Garden, and on the east, where a straggling growth of slums around Whitechapel, Wapping, and Henry VIII's dockyard at Deptford marked the beginning of the East End. The West End was also foreshadowed, not so much by the line of mansions of the new nobility along the Strand as by the lodgings between London and Westminster of numbers of gentlemen of wealth and fashion who then came to town for the season—*i.e.*, the legal terms or sittings. The occasional contact of the City and the court was also severed. Henry VII had rebuilt and sometimes used Baynard's Castle in Blackfriars. Henry VIII built a palace at nearby Bridewell, but in 1529 he moved west and began his conversion of Cardinal Wolsey's York Place into Whitehall Palace and of a suppressed leper hospital into St. James's Palace (the British court is still officially designated the Court of St. James's). In the reign of Elizabeth I the Tower ceased to be used as a royal residence. The Tudors, however, never lost London's allegiance. Even when its loyalty might have faltered under Mary I, for London was overwhelmingly Protestant, it held firm against Sir Thomas Wyatt's rebellion in 1554. Elizabeth, especially, based her strength on its enthusiastic loyalty, on its money and militia, for London dominated England as never before or since. It provided a quar-

ter of the men for service abroad in 1585 and 1589, and in 1588 it formed its forces into "trainbands" against the threat of Spanish invasion. It was the presence of the trainbands at Turnham Green that prevented Charles I from attacking London in 1642. The rift between the king and the City had long been widening. The king had flouted the City's privileges and trading interests; the City had disobeyed royal injunctions. When the Civil War began, London, soon encompassed by forts, provided the core of parliamentary support, and its allegiance was a major reason for Parliament's success.

After their unhappy experiences during the Commonwealth, the citizens of London rejoiced at the restoration of Charles II in 1660. By then London was probably the most populous city in Europe with perhaps 500,000 inhabitants (the next largest English town, Bristol, had only 30,000) and in it was concentrated the bulk of English capital and talent. Building had continued on the east and west, and for the first time there was evidence of planning in some of the developments. Covent Garden (*q.v.*) had been laid out as the first of London's squares in the 1630s and was soon followed by Southampton Square and Lincoln's Inn Fields. In these areas, London was becoming a city of brick. Elsewhere, however, timbered houses persisted, and the overcrowded and insanitary conditions of the City and its immediate suburbs, and the consequent threat of epidemics, were worse than ever before. Outbreaks of plague, beginning with the Black Death (*q.v.*) of 1348, had become increasingly frequent since the early 16th cen-

tury; over 40,000 Londoners had died of it in 1625. The last and worst of the epidemics, the Great Plague, began in the autumn of 1664. At its climax, about 7,000 plague deaths were recorded in a week. By December 1665 parts of the city were deserted; more than 75,000 Londoners had died and many thousands more had fled. (See also **PLAGUE**.) (B. W. Sp.)

E. LATER STUART AND HANOVERIAN LONDON

1. Reconstruction After the Great Fire.—The Great Plague was followed in September 1666 by the worst fire in London's history. Begun accidentally, in the house of the king's baker in Pudding Lane near London Bridge, in the four days Sept. 2–5 it burned all save the northeastern and the extreme western parts of the City. The Royal Exchange, the Custom House, Guildhall and nearly all the civic buildings, the halls of 44 of the livery companies, St. Paul's itself, and 87 of the parish churches, besides about 13,200 houses, were destroyed. Barely one-fifth of the City was left standing. In that fifth, the citizens began reconstruction. Gresham College was converted into a temporary Royal Exchange, thus giving the merchant and trading community an adequate centre, and king and City each appointed three eminent "architects" to devise plans for a general rebuilding. The optimism of their initial decision that high streets should be 70 ft. (21 m.) wide and "alleys, if any, 16" faded as the difficulties appeared, especially those of financing the work. Parliament was apathetic. Fire insurance was a thing of the future, supplies and labour had to be assured and disputes resolved. Eventually two statutes of 1667 and regulations agreed between Charles and the City allowed building to start; by the end of 1671 almost all the houses had been built.

The new City showed many improvements. Well-designed brick houses replaced half-timbered. The streets were wider and straighter, the markets enlarged or re-sited, the Fleet River canalized, the quays below London Bridge raised, and Guildhall given a direct link with the river via the new King and Queen streets. Work on the churches followed, as supplies of money and stone became available. Many of the tiny parishes were combined; 49 churches and the great domed St. Paul's, all built by Sir Christo-

pher Wren, set the stamp of his genius on the new city.

The end of the rebuilding did not mark the end of the City's troubles. For centuries the City and London had been synonymous, but expansion under the Tudors had carried the tide of building beyond its boundaries. From the days of Elizabeth I, successive governments had tried to limit this expansion, not altogether without success. The fashionable, well-built streets around Covent Garden had been authorized under Charles I, and building had gone on all round the City's perimeter; but it had been hampered by restrictions supported by both the central and the civic authorities. After the fire, with the enforced removal of perhaps 100,000 people, such limitation was impossible, and the subdivision and development of the great houses on both sides of the Strand was matched by new building in Westminster, in the fields which became St. James's Square, in Soho, Clerkenwell, Whitechapel, and on both banks of the river below the bridge. The City, despite its charters, was forced to accept new markets, such as Covent Garden and Spitalfields, for the food and the fodder required for these new areas, and it had to surrender, in fact if not in name, much of the jurisdiction over them. Left to the control of the justices for Middlesex, the markets gradually drifted into the condition so sharply criticized by Henry Fielding and his half brother, Sir John (*qq.v.*).

2. Local Government and National Politics.—Within the City, the direct responsibilities of the individual householders dwindled and the Courts of Aldermen and Common Council gradually took over from ward and parish the supervision or the actual management of that whole range of urban economy, from paving and lighting to drainage and sewers, paid for nowadays by a consolidated local rate. The process was slow, beginning in 1667 with the appointment by the Common Council of a body of its own members as Commissioners of Sewers and Pavements empowered to levy rates, but, in the main, it gradually produced in central London conditions which, if primitive by modern standards, were the envy of most visitors from Europe.

Politically the City remained as important as ever. The struggle between the sides soon to be known as Whigs and Tories was reflected in its elections and in the composition of its grand juries.

BY COURTESY OF THE LONDON MUSEUM

"THE GREAT FIRE OF LONDON, 1666," A 17TH-CENTURY PAINTING DEPICTING THE EVENING OF THE THIRD DAY

Charles II's attempt to control Parliament by controlling borough electorates reached its zenith when, after proceedings under a writ of quo warranto, the City's charters were declared forfeit (1683) and aldermen and officers unacceptable to the crown were replaced by royal nominees. The king's victory did not last long. James II, before his flight in 1688, made full restitution, but the City was not appeased. The lords spiritual and temporal met in Guildhall, within the protection of the City and its trainbands, to draw up the declaration of allegiance to William of Orange. The Common Council voted an address welcoming him. The value attached to the City's support was shown by the summons to the lord mayor, the aldermen, and 50 representatives of the Common Council to attend the National Assembly which met in London after William's arrival.

For the next 80 years, the City, whose electorate was the liverymen, men whose numbers and political education made them the most formidable urban constituency in the realm, usually supported the government. In matters of finance, the foundation of the Bank of England (1694), with members of the Court of Aldermen prominent on its court, marked the end of the Stuarts' enforced reliance on shifting syndicates and an unenthusiastic corporation. Henceforward, whether in peace or in war, the London money market was to be a prime factor in affairs of state. London's commercial and financial interests, growing with every expansion of the king's dominions, had much to gain from settled government. In the Jacobite rebellions of 1715 and 1745 London gave full loyalty to the throne, and during the Seven Years' War (1756-63) William Pitt gained much from its admiring support.

Under George III relations were more strained. Many Londoners ardently supported the turbulent John Wilkes (*q.v.*), and "Wilkes and liberty" was a popular cry in the city. In 1771 a struggle over the reporting of debates in Parliament saw Brass Crosby, the lord mayor, committed to the Tower. The advent to power (1783) of the Younger Pitt brought better relations, but the cause of parliamentary reform had strong support in the City, and Common Hall (the general meeting of the liverymen) was a source of much unwelcome advice to the king or the government.

3. London by the Early 19th Century.—By 1820, when George IV succeeded to the throne, the whole character of London had changed. Its population, perhaps 500,000 in 1666, had increased to more than 1,100,000. The number of its houses had grown even more rapidly. Villages and hamlets—Marylebone, Islington, Bethnal Green, and Newington are examples—which in 1666 had been the objects of Samuel Pepys's summer outings, had become part of the built-up area. Some of the building had been the planned, well laid-out work of great landowners whose suburban fields had become ripe for development; some was the sorry work of the small and greedy. Examples are still obvious today. The Bedford, Portman, and Foundling estates produced streets and squares which embellished the town. Parts of Stepney and Bethnal Green were ill-built cottage terraces. Agar Town, which lay near the modern King's Cross and St. Pancras, was a scandal.

The changes brought by the years 1689-1820 had followed no conscious plan. Inside the City its government was in full control and reasonably active. Beyond its boundaries, unchanged since the Middle Ages, government, services, and communications for the new areas came piecemeal. The important developers obtained local acts of Parliament enabling them to levy rates out of which to finance paving, lighting, cleansing, and the watch. The popularity of their streets depended in part on such services and they were usually adequately administered. Lesser men left a legacy of rookeries (densely populated slum buildings) and neglect for later generations to clear. In communications generally, the City played a leading part. Once its opposition to a second Thames bridge had been overcome and Westminster Bridge had been built (1739-50), it built Blackfriars (1756-69) and accepted without opposition the companies which built Waterloo (1811-17) and Southwark (1813-19) bridges. These all entailed approach roads and, between them, opened the marshy Surrey bank for building.

While turnpike roads were improving the entries into London, the New Road (now the Marylebone, Euston, and City roads) was

BY COURTESY OF THE TRUSTEES OF THE BRITISH MUSEUM

"THE VIEW AND HUMOURS OF BILLINGS-GATE," AN ENGRAVING BY ARNOLD VANHAECCKEN DATING FROM 1762

started in 1756 as the first great bypass, and internal communications were eased by the covering over of the Fleet River (now Farringdon Street), the removal after 1760 of the City gates, and the work done under the Westminster and City Paving acts. The congestion, delays, and robberies of the port were at last eased by the opening in 1802 of the West India Docks and later of the London (1805) and the St. Katharine (1828) docks.

Socially, commercially, and financially, London was the hub of the kingdom and these improvements in communications were essential. As a corollary to its great wealth, fed by the profits of the East and West Indies' trade and by trade with most of the known world, it reigned supreme in England in matters of the theatre, literature, and the arts. It was the London of David Garrick, Oliver Goldsmith, Samuel Johnson, and Sir Joshua Reynolds, of the great furniture makers and silversmiths, and of the world-famous foreign musicians. But its size brought increasing problems. The opening of new waterworks, the modernization of the old, and the installation of steam pumping engines (1805-27) much improved the quantity if not the quality of water available.

F. THE 19TH AND 20TH CENTURIES

1. Government and Services.—Although new dispensaries and new or enlarged hospitals were reducing mortality, the former riverside town required new forms of government, of communications, and of sanitation if it was to continue to grow. These were slowly and painfully evolved in the London of 1820-1914. Against a background of statistics which showed the population of the built-up area rising from 1,225,694 (1821) to 6,586,269 (1901) the innovations came piecemeal. In 1829 a centralized Metropolitan Police Force was provided, under the ultimate control of the home secretary, in place of the uncoordinated watchmen and parish constables who had been helpless against most disturbances, let alone against the Gordon "No Popery" riots (1780) (*see* GORDON, LORD GEORGE). The lighting of streets by feeble oil lamps was revolutionized by the introduction of gas, and soon the Gas Light and Coke Company (1810) was followed by similar companies scattered throughout London. George Shillibeer's omnibuses (1829) began a revolution in road transport, and carriage by rail came less than ten years later. The year 1845 brought a great inquiry into public health, with the exposure of London's worst deficiencies, 1852 legislation ensuring a purer water supply, and 1855 a statute (the Metropolis Management Act) which combined a number of the smaller units of local government and replaced the medley of franchises with a straightforward system of votes by all ratepayers. Major works, such as main drainage, were put in the hands of a Metropolitan Board of Works operating for the whole of the built-up area.

The momentum of these changes, established by such diverse reformers as Bishop C. J. Blomfield, Sir Robert Peel, Edwin (later

Sir Edwin Chadwick, and the earl of Shaftesbury, continued throughout the century. New churches, new schools, better law and order, main drainage, and care for the outcasts were some of the reformers' legacy; Trafalgar Square, The Embankment, and roads driven like Shaftesbury Avenue and Charing Cross Road through the worst of the rookeries are their most obvious monuments. The changes in government continued, if not so drastically. The London County Council superseded the Metropolitan Board of Works in 1888, the vestries were transformed into metropolitan boroughs by the London Government Act (1899), and the various water companies combined in 1902 into a publicly owned Metropolitan Water Board.

Public and private works continued to transform the face of London. The opening of the Metropolitan Railway (1863) and the making of Holborn Viaduct (1869) were accompanied by the building of new Thames bridges and the rebuilding of Battersea, Westminster, Blackfriars, and London bridges. After years of discussion and agitation, the road bridges outside the City passed into public ownership and the tollgates disappeared. All the main railways carried their lines into London, and at Victoria, Charing Cross, Blackfriars, and Cannon Street they crossed the river to the northern bank. It was an era in which an abundance of initiative and of capital was joined to abundant labour to make the widest use of new skills, cheap transport, and copious raw materials.

The Great Exhibition of 1851, opened in Hyde Park by Queen Victoria, typified the age. London had become the shop window of the world, yet, in matters of daily life, much of it was brand new. A writer in the *Times* (London) of July 28, 1853, underlined this: "It does not take a very old man to remember when there was neither a gas lamp, nor a cab, nor an omnibus, nor a steam vessel, nor a plate glass window, in a city of which these things are now essential ingredients."

Technical progress continued, gradually altering the lives of Londoners and the face of the town. Cheap suburban trains enabled the skilled artisan to live farther and farther from his work. The London School Board, established under W. E. Forster's Education Act (1870), set about the task of providing elementary education for all. Trams, or streetcars (horse-drawn), after an unsuccessful beginning in 1861, became important in the 1870s and a major factor in metropolitan transport as their electrification developed in the first years of the 20th century. By then electricity was being used as the motive power for traffic below ground, the prince of Wales opening the world's first electric underground railway, from King William Street to Stockwell, on Nov. 4, 1890. With the arrival, before 1914, of the gasoline-driven omnibus, the outline of transport in modern London was complete and the way opened for still faster development of suburbia.

Inevitably this was accompanied by rising land values in the central zone, by the construction of ever larger offices, factories, and warehouses in place of small houses, and by a continuous outlay of public and private funds on better housing and street improvements. World War I, with air raids inflicting 2,632 casualties on London, brought only a temporary pause. Peace saw resumed

development on a mounting scale. As a national and in some respects a world capital, London required institutions capable of meeting its needs. An era of amalgamation and expansion ensued. From banks to hospitals, and telephone exchanges to power stations, almost all was expanded. Street congestion, well-known in the 1850s, was worse in the 1930s, despite the rationalization of traffic authorities. (For conditions after World War II see *Communications: Roads*, below.) By 1939 the population of the Greater London conurbation exceeded 8,000,000.

2. Reconstruction After World War II.—World War II, with evacuation planned and unplanned and heavy damage by air raids, brought the greatest setback in the history of modern London. Air attack killed more than 30,000, injured more than 50,000, damaged most public buildings, and, in such areas as the City and Stepney, obliterated whole sections of the street system. Westminster Abbey and the Houses of Parliament were damaged but saved, as were St. Paul's and Guildhall in the City. Ordinary houses and dockland suffered severely.

The end of hostilities brought a gradual return of many evacuees and a housing shortage made worse by the ravages of dry rot. Reconstruction, hampered by the shortage of most materials, began at once—and with the advantage of plans and surveys already put forward. J. H. Forshaw and L. P. Abercrombie had produced in 1943 a plan for the County of London, supplemented in 1944 by Abercrombie's plan for Greater London. C. H. Holden and W. G. Holford reported on the City (1947). The Town and Country Planning Act (1944), followed by acts of 1947, 1954, and 1959, gave unprecedented powers of purchase, direction, and control. The urgency of the Festival of Britain (1951) produced Lansbury (a redevelopment in Poplar) and the Royal Festival Hall, but the most significant postwar features have been the vast investment in new houses, the restoration of the services and Port of London, the general acceptance of a planned urban economy, and the sustained effort to divert industries to new or expanded towns outside London. Even so, 1961 began with a census return which showed the population of Greater London as 8,171,902, while the recommendation of a royal commission (1960) to redraw the boundaries was implemented in the London Government Act 1963 by the creation in April 1965 of the Greater London Council (see *Government*, below). (T. F. R.)

IV. TOPOGRAPHY

A. CENTRAL LONDON

Central London by popular definition is an area of about 30 sq. mi. (26 sq. km.), bounded roughly by (and including): the South Kensington museums; Paddington, Marylebone, Euston, and King's Cross railway termini; the Angel, Islington; Shoreditch; High Street; Spitalfields Market; the Royal Mint; London Bridge Station; the Elephant and Castle; Vauxhall and Chelsea bridges; and Sloane Square. It thus includes the City of London. The central point is conventionally taken as Charing Cross. Although the resident population of Central London has declined for many decades, the working force, and consequently the commuting problem, have grown ever greater. Central London falls readily into two parts, with different histories and functions: the City of London; and west central London and the West End.

1. City of London.—The City's functions are commerce, trading and finance (see *Economic Activities*, below). It handles a large segment of the nation's wholesale trade. The financial institutions are remarkably concentrated within half a mile of the Bank of England. Lombard Street, running southeast from the bank, is the traditional home of English banking; it is named after the Lombards from Italy, the chief financial power in 14th- and 15th-century England. The City has little manufacturing except the newspaper printing quarter along Fleet Street.

The topography of the City has altered little over the centuries. The central institutions (the Bank of England, the Mansion House, the Royal Exchange, the Stock Exchange) stand on a triangular space where eight streets meet; thereabouts the main Roman streets also met. The medieval street pattern, in which names reflect the City's trading preoccupations (Cheapside, meaning the bargain quarter; Milk Street; Bread Street; Cornhill, meaning the

BY COURTESY OF THE LONDON TRANSPORT BOARD

VICTORIAN DIGNITARIES TAKING A TRIAL TRIP ON THE METROPOLITAN RAILWAY PRIOR TO ITS OPENING IN MAY 1863

as well as the position of the gates in the old wall (Ludgate, Newgate, Aldersgate, Cripplegate, Moorgate, Bishopsgate, Aldgate), were retained as the basis for rebuilding after the Great Fire, despite improved plans drawn up by Wren and others.

With certain exceptions it was again retained after the air-raid destruction of World War II. But the brick-built City merchants' houses, which arose after 1666, have all been replaced by offices, and until 1939 these were of uniform but limited height. In post-war planning, however, opportunity was taken to vary building heights in order better to utilize the available daylight. The resulting tall blocks have revolutionized the traditional City skyline, in which the chief accents were St. Paul's Cathedral and the spires of Wren's other churches. On Tower Hill a garden containing the great Merchant Navy Memorial, an extension of the 1914-18 Merchant Seamen's Memorial, was opened in 1955. Two areas wholly rebuilt to segregate pedestrians from the road traffic are the area round St. Paul's Cathedral and the 40-ac. (16-ha.) Barbican site in the north of the City which includes a building 350 ft. (107 m.) high. New Britannic House, near Moorgate, reached 395 ft.

2. West Central Area and West End.—In the development of the area west of the City, at least five elements can be distinguished. First in point of time was the governmental function, which the late Saxon and Norman kings established round the palace and abbey church at Westminster. The existing government quarter stretches along the riverside, including the Houses of Parliament round the ancient palace; Westminster Abbey; the seat of the prime minister and cabinet in Downing Street; and the great blocks of government offices along Whitehall and adjacent streets. The seat of the crown was moved in Tudor times to St. James's Palace, across the royal park, and in the 19th century to Buckingham Palace nearby. Second was the legal quarter that grew up in the 14th century in the west central area between the City and Westminster, north and south of Fleet Street. There are still found the four inns of court together with the minor inns of chancery (*see* INNS OF COURT AND CHANCERY), solicitors' offices, and the law courts.

Most striking was the third element: the growth after 1600 of a residential area for the rich. At the Reformation monastic land was given to the nobility. In 1631 one of these, the duke of Bedford, used some of his ground to build Covent Garden, a formal square modeled on the piazza at Leghorn, Italy, and on the Place des Vosges in Paris. It became the pattern for the development of the West End for more than 200 years. Houses round the new squares, or on the formal streets between them, found a ready market among those enriched by agriculture or trade.

The late 17th century saw the building up of the areas known as St. James's and Mayfair, to the north of the royal parks of St. James's, Green, and Hyde, which were fashionable resorts. In the 18th century Mayfair was completed and building spread north of Oxford Street into Marylebone (the Cavendish-Harley and Portman estates) and to the northeast in Bloomsbury, where the formal layout reached its apogee. In the early 19th century Belgravia was laid out and by mid-century the marshes of Pimlico, to the south, had been reclaimed and the land built over. By 1850 the West End was the home of the rich. To serve it there developed the specialized luxury shops of Mayfair and St. James's: the bespoke tailors of Savile Row, the gownmakers of South Molton Street, the jewelers of Bond Street, the wine merchants of St. James's, and the original West End theatres; while in the early 19th century St. James's became London's clubland.

From about 1870 onward a fourth element entered, and the character of the West End changed rapidly. Higher living standards changed luxuries into articles of popular consumption. Along Oxford Street, popular department stores arose; one of the biggest, Selfridge's, was built in 1906-09. Theatres multiplied, a separate theatre area developing along Shaftesbury Avenue. The cosmopolitan area of Soho (*q.v.*), and the Charlotte Street area north of it, became the home of specialized restaurants. In the 1920s the Leicester Square area became the main centre for luxury motion-picture theatres. These new functions often brought with them new manufactures; thus a vast garment industry grew up

round Oxford Street, serving the popular dress shops. All these changes swelled the working population of the zone and diminished the resident population after 1900. Lastly, since 1920 but especially since 1950, the West End has become an office area. The character of Mayfair and St. James's has changed almost beyond recognition as big new blocks have replaced the former town houses. In Marylebone and Bloomsbury many of the houses, formally preserved, now house only caretakers.

But the character of the West End remains governmental, professional, and cultural rather than commercial. Bloomsbury is dominated by the buildings of the University of London (*see* LONDON UNIVERSITY) which cluster round the British Museum, and by the offices of publishers; Marylebone is the home of clinics and specialists' consulting rooms; Mayfair, Kensington, and Belgravia house many embassies of foreign governments.

B. EAST END AND OUTER LONDON

1. East End.—The quarter lying east of the rough line Shore-ditch High Street-Houndsditch-Aldgate-Tower Bridge, and stretching east as far as the River Lee is called the East End and is largely a 19th-century creation. In the Middle Ages it was part of the great parish of Stepney, centred upon the Saxon village and church of St. Dunstan's. Ribbon building took place along the main roads (Whitechapel Road and Wapping High Street) by the early 17th century, when east London had already acquired its reputation as the home of the poor. But the great expansion came between 1820 and 1880, following the construction of the St. Katharine Docks and the growth of manufacturing industries (clothing and furniture) needing quantities of cheap sweated labour. Overcrowding, casual employment, and subsistence wages made the 19th-century East End an area of great poverty. In 1840 among the labouring classes of Bethnal Green 60% of all deaths were children under 5; the average age of death was 16. There was still no drainage in 1850. About 50 years later the great survey by the social reformer Charles Booth (*q.v.*) found 38% of the East End's population in poverty.

But after 1900—especially after 1940—the East End altered greatly. Its 1961 population was less than half the 1901 figure, the result of slum clearance, bomb damage, and natural migration as living standards rose. The Stepney-Poplar Redevelopment Area (470 ac. [190 ha.]) is being rebuilt completely as a "New Town" within London for 100,000 persons, the largest urban renewal plan in the United Kingdom. The old monotonous rows of two-story cottages are becoming a historical memory as they are replaced by four-story maisonettes and tall slab blocks of flats, set among gardens and parks.

The old immigrant communities, once prominent in East End life, have been integrated and are much shrunken. Chinatown (Limehouse) has become a mere collection of restaurants along West India Dock Road, and the Jewish community of Whitechapel largely migrated to other parts of London after 1930. There still survive, however, clearly marked industrial zones, each with its distinctive character: the furniture quarter of Shoreditch and Hackney Road; the Jewish clothing quarter of Whitechapel round the historic Petticoat Lane market (in Middlesex Street); and dockland with its heavy industry.

2. Outer London and Suburbs.—No enduring definition of the London suburbs is possible; what is suburb today could be town tomorrow. In the Middle Ages, Fleet Street was in *suburbio* to the City; in the 18th century Bloomsbury and Marylebone were suburbs, in the 19th Islington, St. John's Wood, and Camberwell. There is, however, an enduring suburban ideal: one of seclusion, of retreat from the bustle of the town. But as work usually remained in town this implied effective transport facilities once the suburbs had grown beyond walking range; *i.e.*, after about 1850 (*see* Communications, below). Only after the extension of the underground railways into the country, and the electrification of the surface lines south of the river, did the suburbs proliferate. In 1914 the limits of built-up London were still Ealing, Cricklewood, Hornsey, East Ham, Lewisham, Wimbledon—places 5-8 mi. (8-13 km.) from the centre. By 1939 the limits were Watford, Edgware, Enfield, Loughton, Hornchurch, Orpington, Purley,

and Esher; the radius had doubled, the area had increased five times. By the 1960s suburbia had extended well into the counties adjoining the Greater London perimeter (Essex, Hertfordshire, Surrey, and Kent).

The need for seclusion dictated the form of the suburb. Until about 1850 the fashionable London house was one in a terrace, built in straight streets or formal squares. But the new suburbs after about 1820 had separate houses with their own gardens, grouped informally along irregular avenues. The models were John Nash's Park Village (1818-25) near Regent's Park, and the spontaneous extensions of Hampstead Village in the same period. The forms were copied in villages as diverse as Dulwich, Highgate (*q.v.*), Camberwell, and Holland Park in the next 80 years. But until 1918 they were a luxury.

Between 1918 and 1939, however, speculative builders took the form up and, following the electric railways, reproduced it for many miles across Essex, Surrey, and Kent. The romantic cottages of Nash were standardized and debased into the detached and semi-detached mock-Tudor patterns which line the avenues and arterial roads of these suburbs. They were built at low densities (about 12 houses per acre), for land was still cheap. Only rarely is the monotony broken by industry (mainly in well-defined pockets) or by the outer London shopping centres, many of which (Kingston upon Thames, Croydon, Harrow, Ilford, Bromley) developed out of the original village nuclei or the country market towns.

There are separate articles on the London boroughs (for list see *Government*, below), and there are also articles on BILLINGS-GATE; BLACKHEATH; BRIDEWELL; BUCKINGHAM PALACE; CHARING CROSS; CHARTERHOUSE; CLERKENWELL; COVENT GARDEN; DULWICH; HAMPTON COURT; HIGHGATE; KENNINGTON; LIMEHOUSE; RANELAGH; SOHO; STREATHAM; TOWER OF LONDON; VAUXHALL. (P. G. H.)

C. THAMES EMBANKMENTS AND CROSSINGS

1. Embankments.—The Victoria Embankment, commonly known as The Embankment, runs from Blackfriars Bridge to Westminster and was built in 1864-70. The river front at that time was disfigured by dilapidated buildings and offensive mudbanks. About 37½ ac. (15 ha.) of mud were reclaimed for public gardens and a roadway 100 ft. (30 m.) wide beneath which runs the District Railway. The engineer was Sir Joseph William Bazalgette. When the plan was first put forward, to meet the need for main drainage, it was found that an embankment with pipes buried behind it would cost no more than a pipeline along the foreshore. Accordingly the first alternative was adopted. The Chelsea Embankment, 1 mi. (1.6 km.) long and providing for a roadway of 70 ft. (21 m.), also accommodates main drainage. It runs between Chelsea and Battersea bridges and was opened in 1874. Together the Victoria and Chelsea embankments (with Grosvenor Road, constructed at the same time) provide a continuous riverside communication of about 4½ mi. (7 km.), interrupted only by the Houses of Parliament.

On the south bank the Albert Embankment, opposite the Houses of Parliament, was planned mainly for flood prevention and was opened in 1869. About 8½ ac. (3.5 ha.) of foreshore were reclaimed and on this St. Thomas's Hospital and a 70-ft. promenade were constructed. A fourth embankment providing a footway in front of County Hall was opened in 1910. In 1951 it was extended to Waterloo Bridge and gardens were laid out on land denuded of buildings during World War II. This site, known as the south bank, was the home of the Festival of Britain (1951) and has been set aside as a cultural centre to contain the Royal Festival Hall and National Film Theatre (both built in 1951), and the National Theatre and an opera house, riverside memorial gardens, a hotel, and the new Patent Office.

2. Bridges.—From Roman times until the 18th century London Bridge was the capital's only bridge. The first stone bridge, begun in 1176, was removed in 1832; it stood about 100 ft. below (1) the present London Bridge (1824-31), which was designed by John Rennie. Downstream is (2) Tower Bridge (1886-94), designed by Sir Horace Jones and Sir John Wolfe-Barry. Upriver from London Bridge are: (3) Cannon Street Railway Bridge; (4)

Southwark Bridge, Rennie's old "Iron Bridge" of 1813-19 having been replaced by one opened in 1921; (5) Blackfriars Railway Bridge and, close by, (6) Blackfriars Bridge, opened in 1769, rebuilt 1865-69, and widened 1907-09; (7) Waterloo Bridge, by Sir Giles G. Scott, officially opened in 1945, replacing a celebrated bridge erected by Rennie in 1811-17; (8) Charing Cross Railway Bridge (1860-64), attached to which is the Hungerford Footbridge; (9) Westminster Bridge (completed 1862), replacing the 1739-50 bridge of Wordsworth's sonnet; (10) Lambeth Bridge (1929-32), replacing an 1862 suspension bridge built at the site of a ferry for transporting horses; (11) Vauxhall Bridge (1906), replacing one built 1811-16; (12) Victoria Railway Bridge; (13) Chelsea Bridge (rebuilt 1937 to replace one of 1858); (14) Albert Bridge (1873); (15) Battersea Bridge (1890), replacing a timber bridge of 1773 renowned as the subject of a Whistler picture; (16) another railway bridge; (17) Wandsworth Bridge, opened 1873 and reconstructed 1936-40; (18) a bridge carrying the District Railway and a footway; (19) Putney Bridge (1882-86), widened in 1933, replacing a wooden toll bridge of 1729; (20) Hammersmith Bridge (1887), replacing a suspension bridge of 1827 which had been the first of its kind across the Thames; (21) Barnes Bridge for pedestrians (1933); (22) Chiswick Bridge (1933); (23) King Edward VII Bridge, Kew (rebuilt in 1902); (24) Twickenham Lock and Twickenham bridges (1933); (25) Richmond Bridge (1777); (26) Kingston Bridge (1828); and (27) Hampton Court Bridge (rebuilt 1933).

3. Tunnels and Ferries.—The Thames Tunnel, constructed by Sir Marc and Isambard Kingdom Brunel, opened in 1843 between Shadwell and Rotherhithe, was an attraction to Victorian Londoners, with its shops and stalls, and was the starting point of a walk into Kent by East London pedestrians. The tunnel never paid its way and now carries the District Railway between Whitechapel and New Cross. Four tunnels of the underground railway system go under the Thames between Charing Cross and London Bridge. There are three ferries: the Limehouse Hole Ferry, the Deptford Ferry, and the Woolwich Free Ferry. The Greater London Council maintains the latter (opened 1889) and also the following tunnels (west to east): Rotherhithe, opened 1908, 6,833 ft. (2,083 m.); Greenwich (footway only); Blackwall (1897) with its duplication opened 1966, 6,200 ft. (1,900 m.); Woolwich (footway only), opened 1912, 1,655 ft. (504 m.). (X.)

V. ARCHITECTURE

Parts of the walls which include Roman work can still be seen at Tower Hill, Monkswell Street (east of Aldersgate Street), St. Giles Cripplegate, and the General Post Office (GPO). Beneath the Coal Exchange (itself demolished in 1963) are the remains of a Roman hypocaust, and there are mosaic pavements inside the Bank of England. The Temple of Mithras, excavated on the site of Bucklersbury House in 1954, was moved to a nearby site in Queen Victoria Street. A late Saxon rood panel remains at St. Dunstan's Church, Stepney. Place names indicate considerable Danish influence in and around the City (*e.g.*, St. Clement Danes Church, Strand). Immediately before the Norman Conquest an impressive church was built at Westminster for Edward the Confessor, of which the Chapel of the Pyx and the monks' dormitory undercroft remain within the abbey precincts.

1. Medieval and 16th-Century Buildings.—The Norman invasion resulted in major building activity in London, of which much is left. The Tower of London (*q.v.*) is outstanding. Many merchants' houses were built on vaulted stone crypts; houses surviving at Lincoln show the type. The wave of prosperity in the 12th century led to extensive rebuilding of churches in stone. Of these, the choir of St. Bartholomew the Great, Smithfield, founded in 1123 (nave completed in the 13th century), still stands. The rotunda of the Temple Church (consecrated 1185) remains, though much restored; and the crypts of St. John's Church, Clerkenwell (1140-85), and St. Mary-le-Bow (*c.* 1090) can still be seen.

Life in medieval London revolved around the central market area of Cheapside. The City government is traditionally associated with this area, in which stood the halls of the city companies and where Guildhall remains with much important medieval work.

(new roof by Sir G. G. Scott finished in 1954). As trade increased, much of the foreshore was reclaimed, the space within the walls was built over, and extramural building along the riverbank began. The network of narrow streets which remains shows how overcrowded the City was; about one-quarter was occupied by religious houses and their holdings. There were 106 churches, serving a population so dense that the present Bank of England covers the sites of two parishes. Rebuilding in City churches continued in the late Middle Ages, but much was lost in the Great Fire. Surviving churches are St. Etheldreda, in Ely Place, Holborn (the only pre-Reformation church in London occupied by Roman Catholics), built about 1300 as the private chapel of the bishop of Ely; Lambeth Palace Chapel (c. 1230) with undercroft (c. 1200, restored after bombing); and, in the City, St. Helen's, Bishopsgate (with Perpendicular arcade), St. Ethelburga, Bishopsgate (with early 15th-century arcade), St. Giles Cripplegate (14th century, rebuilt 1545; damaged by bombing), St. Andrew Undershaft (rebuilt 1532), and the Savoy Chapel, Strand (begun 1505).

Medieval Westminster, on the other hand, centred around the ceremonial of court and abbey. Until the late 18th century the river was the chief highway, and the chain of great houses of the nobility along the Strand linked the City with Westminster. Westminster has some of the finest medieval architecture of London. Westminster Hall was completed in 1097 but modified in 1394–1402 when the magnificent hammerbeam roof was added—one of the finest in Europe. Damaged by incendiary bombs during World War II, the roof has been restored. Westminster Abbey was rebuilt for Henry III between 1245 and 1269; the eastern part, the north and south transepts, and five bays of the nave are of this period (see WESTMINSTER: *Westminster Abbey*).

Southwark Cathedral, though much restored (nave wholly 19th century), contains interesting 13th-century work (retrochoir, chancel, etc.). Several other medieval churches outside the City still stand. The best preserved is St. Margaret's, Westminster, a fine Perpendicular parish church. St. Mary, Stratford-le-Bow (Tower Hamlets), retains much 14th-century work; good medieval west towers survive at the parish churches of Fulham, Lambeth, and Putney. Two fine secular buildings are Crosby Hall (1466–75), which was moved from the City and rebuilt in Chelsea in 1910, and Eltham Palace, Woolwich, with its splendid great hall of the late 15th century. Staple Inn, Holborn, retains its fine half-timbered facade (1586) though extensively rebuilt behind. Archbishop's Palace, Croydon, is an irregular group dating mainly from the late 14th to the late 15th century.

Brick came into wide use for building in the 16th century and thereafter. The brick gateway of St. James's Palace and parts of Lambeth Palace are late 16th century. What is now known as the St. John's Institute, at Hackney, is a well-preserved early 16th-century manor house. The Charterhouse (q.v.), Finsbury, retains much 16th-century work and some earlier fragments. The remnants of Well Hall, Eltham, contain a range of brick buildings of 1568. The front of Sir Paul Pindar's Bishopsgate House, of about 1624, is preserved in the Victoria and Albert Museum. Charlton House near Greenwich (1607) is the only Jacobean house of first importance in London; number 17 Fleet Street retains a Jacobean room ("Prince Henry's Room"; 1600–11); the George Inn, Southwark, has a galleried courtyard of 1676, continuing the medieval tradition; and Cromwell House, Highgate, of about 1637–40, has a fine staircase. Bruce Castle, Tottenham, now a museum, is Elizabethan and late 17th century. Ham House, near Richmond, is also a museum; it was built in 1610 and altered in 1673–75. Boston Manor, Brentford, dates from c. 1622–23, while Forty Hill, Enfield, and Swakeleys, near Uxbridge, belong to the 1630s; all have undergone alterations.

2. Influence of Inigo Jones and Sir Christopher Wren.—The 17th century saw the rise of the individual architect, and that century, which included the working lives of Inigo Jones and Sir Christopher Wren (qq.v.), gave to London some of its finest buildings. Inigo Jones initiated the use of a carefully worked out classicism. He worked in the court circle and built, in the manner of Andrea Palladio, the Queen's House, Greenwich (1617–19; 1629–37), and the Banqueting House, Whitehall (1619–23). Inigo

Jones also designed Covent Garden Piazza (begun 1630). Of the Lincoln's Inn Fields scheme, begun about 1638 under the inspiration of Covent Garden, Lindsey House (possibly by Nicholas Stone) remains. The typical 18th-century London square derives from these two schemes. John Webb carried on in Jones's tradition and began work at Greenwich on a royal palace; his work comprises the eastern part of King Charles's Block (1665–68) and the palace was continued, as the Royal Naval Hospital, mainly by Sir Christopher Wren. The extramural expansion of London that had begun on a large scale in the Elizabethan Age continued unchecked, and the speculative builder made his appearance. Noteworthy of the period is the chapel of Lincoln's Inn (1617–23; restored), built in an interesting revived Gothic style; the fine Ashburnham House (before 1662), remains in Westminster.

In the rebuilding after the Great Fire the earlier street plan was followed in the main. In the interests of fire prevention, private houses were then built in brick and stone. Among the lost medieval works were most of the halls of the city companies. They were rebuilt in brick and stone on similar lines to the private houses. World War II again destroyed most of them; Skinners' Hall and Vintners' Hall still stand, with interesting woodwork, and Apothecaries' Hall, which retains its courtyard, is a valuable example of the former appearance of many City houses.

Before World War II, the 32 surviving examples of parish churches that were rebuilt under the supervision of Wren, using the medieval ruins as foundations, formed an unrivaled group of works in the English Baroque style. The beautifully varied steeples gave great charm to the City skyline. In many cases steeples have survived, including the two finest, St. Bride's, Fleet Street (1701–03), and St. Mary-le-Bow (1680). The only City churches to have survived the bombing intact are St. Benet, Paul's Wharf (1677–83); St. James, Garlickhithe (1676–83); St. Magnus the Martyr, London Bridge (1671–1705); St. Margaret Patens (1684–87); and St. Mary at Hill (1670–76). Some of the damaged churches have been restored. St. Paul's Cathedral (1675–1710), Wren's masterpiece, was almost undamaged and still dominates the City. Other buildings by Wren in London are Greenwich Observatory (1675–76), parts of the Royal Naval Hospital, Greenwich (1696–1705); Chelsea Royal Hospital (1682–91); and almost certainly Morden College, Blackheath (founded 1695); also work at Kensington Palace (1689–1702); and the Monument (1671–76) commemorating the Great Fire.

In the early 18th century, the rapid growth of London continued. Gray's Inn, Lincoln's Inn, Inner Temple, and Middle Temple were almost entirely rebuilt, and the distinctive character of the period has been retained in spite of further modification and wartime damage. The squares, the most distinctive unit of Georgian town building, can be seen in the areas east and west of the City. Between 1710 and 1730 a number of fine churches built to serve these regions brought to prominence a new generation of architects following in the footsteps of Wren. Worthy of note are: St. Mary-le-Strand (1714–17) and St. Martin-in-the-Fields (1722–26), both by James Gibbs; St. Mary Woolnoth (1716–27), St. George, Bloomsbury (1720–30), and Christ Church, Spitalfields (1714–29), all by Nicholas Hawksmoor; and St. George, Hanover Square (1712–25), by John James. In the City, the Mansion House was built in 1739–52 by George Dance the elder on the site of a market. This was the first of the group of grandiose buildings marking the centre of activity in the City. Subsequent rebuilding there displayed the same spirit. The ancient hospitals of London were rebuilt and several new ones constructed on the outskirts; work begun in 1730 by James Gibbs is to be seen at St. Bartholomew's Hospital (founded 1123). William Kent designed the Horse Guards building before his death in 1748, and the work was executed by John Vardy in 1751–58. Roehampton House, designed by Thomas Archer in 1710–12 for Thomas Cary, was enlarged by Sir Edwin Lutyens for use as a hospital. Christwick House, in Palladian style, was built by Lord Burlington in the 1720s, probably to his own designs, and has decorations by William Kent. Not far away are Syon House, Isleworth, a 16th-century house whose interior was remodeled (1762–69) for the duke of Northumberland by Robert Adam; Osterley House, also remodeled

CENTRAL LONDON AND THE CITY, SHOWING PARKS

CIPAL STREETS, BUILDINGS AND RAILWAY STATIONS

by Adam (1761–80); and Horace Walpole's Strawberry Hill, the most influential of all early Gothic Revival buildings in England.

3. Georgian and Regency Architecture.—In the second half of the 18th century a move was made away from the earlier Palladianism of which Burlington House, Piccadilly, built originally in 1663–68 and refaced and remodeled by Colin Campbell in 1715–16, is one of the best examples. Robert Adam (*q.v.*) and his two brothers designed an important scheme, the Adelphi (begun 1768), of which the Royal Society of Arts Building (1772–74) survives. Kenwood House, Highgate (reconstructed 1767–69), is a country house enlarged by Adam and later enlarged again. Adam's Admiralty screen (1760) sets off Thomas Ripley's belatedly Wrenian Admiralty Building (1722–26). Adam designed extremely graceful facades and delightfully varied interiors for his town houses, of which Chandos House, Chandos Street, Cavendish Square (1770–71), and 20 Portman Square (1775–77), now the University of London Courtauld Institute of Art, remain in a good state of preservation. Adam's contemporary, Sir William Chambers, designed the first part of Somerset House (begun 1776), which survives in its riverside setting.

Sir John Soane's work is far more personal and daring than earlier architecture. The Bank of England (1792–1833) was his major work. Part of the screen wall survives but almost all of Soane's work there was destroyed during the reconstruction of 1925–39 to designs by Sir Herbert Baker. Interesting work by Soane can also be seen in his own house (1812–14), number 13 Lincoln's Inn Fields (now the Soane Museum), and in the Dulwich Art Gallery and Mausoleum (1811–14; destroyed 1944 but rebuilt from the original plans).

At the end of the 18th century and beginning of the 19th, important building projects were carried out on the great estates in the northwest of London. The most striking and best preserved is on crown land, the Regent's Park-Regent Street scheme (1811–23), designed by John Nash, with the curved sweep of Regent Street between Piccadilly Circus and Oxford Circus, All Souls' Church in Langham Place, and the porticoed houses of Park Crescent and the Regent's Park terraces beyond. Portland Place had already been laid out by Robert Adam's younger brother James, but little is left. In 1827 St. James's Park was redesigned on "picturesque" principles and in 1827–33 Carlton House Terrace was laid out. This plan included Buckingham Palace; the Marble Arch (1828, in 1851 moved to the top of Park Lane) was designed for the park facade of the palace. Hyde Park was altered at the same time, and Decimus Burton designed (1825 *et seq.*) the lodges to it, the excellent Ionic screen at Hyde Park Corner and the Roman triumphal arch into Constitution Hill, somewhat dwarfed by the quadriga placed on top in 1912. Three buildings of the early 19th century dedicated to learning can be compared; all have flights of steps leading up to massive porticoes: University College (1827–29) and the National Gallery (1832–38), both by William Wilkins; and the British Museum (1823–47, with later additions) by Sir Robert Smirke. St. Pancras parish church (1819–22) by H. W. Inwood (with his father William Inwood) is typical of the church design of the period, with its caryatids and antiquarian copying of classical details. Two interesting late Georgian theatre exteriors survive: Drury Lane (1811), by Benjamin Dean Wyatt; and the Haymarket (1820–21), by John Nash.

4. 19th Century.—In the 19th century London increased considerably in area, and the administrative centre was largely rebuilt. Early 19th-century work is distinguished by the use of stucco, but brick returned to general use later. The railways called for a new type of building for the great termini. These display an interesting early use of cast iron and glass. The earliest, Euston (1836–49), by Robert Stephenson and P. and P. C. Hardwick, had a massive Doric entrance portico (demolished 1962). King's Cross (1851–52) by L. Cubitt has a forthright brick facade. The iron and glass train hall at Paddington (1854) is by the great engineer I. K. Brunel. Victoria Station was built in 1862 and later enlarged. Finally, there is Sir George Gilbert Scott's St. Pancras Station (1868–74); his complex romantic Gothic exterior contrasts with the admirable train shed in glass and iron (1868) by W. H. Barlow. The use of iron frameworks became general. Buildings

were made taller and the exteriors became ever more varied. All types of earlier architecture were copied. The Travellers' (1839–32) and Reform (1838–41) clubs in Pall Mall, both by Sir Charles Barry, were modeled on Italian Renaissance palaces. Outstanding examples of Victorian Gothic in London are: the Houses of Parliament (1837–57) by Barry, assisted by A. W. N. Pugin; the Law Courts, Strand (1874–82), by G. E. Street; and the Albert Memorial (1863–72) by Sir George Gilbert Scott.

During the 19th century many new churches were provided for the growing metropolis. The most remarkable are those of William Butterfield (*e.g.*, All Saints', Margaret Street, begun 1849), stridently original and wholly at variance with time-honoured standards of beauty. Pugin designed the Roman Catholic Cathedral of St. George, Southwark (1841, rebuilt after damage in World War II), and Scott rebuilt St. Mary Abbots', Kensington (1869–79). Other leading London church architects were G. E. Street (St. Mary Magdalene, Paddington, 1868–78), J. L. Pearson (St. Augustine, Kilburn, and St. Michael, Croydon, 1870–80), and G. F. Bodley (St. Michael, Camden Town, 1876–81). The great revival of domestic architecture and design, beginning in the 1860s under William Morris' leadership, is also well displayed in London, mainly in houses in Hampstead, Kensington, and Chelsea—by then centres of artistic people—designed by Philip Webb, Richard Norman Shaw, C. F. A. Voysey, and their followers.

Throughout the 19th and 20th centuries blocks of workers' dwellings were constructed. One of the earliest (1849) remains in Streatham Street, Bloomsbury. In the late 19th and early 20th centuries a restated English Baroque was evolved and used on a number of monumental buildings, several of which are still on the river front. Examples are New Scotland Yard (1891) by Shaw, and County Hall (1912 onward) by R. Knott. Regent Street and Piccadilly Circus (with the statue of Eros as a memorial to Lord Shaftesbury) were redesigned in this style in the early 20th century and the Aldwych with Bush House and the buildings of Kingsway continued this trend into the 1920s. Sir Aston Webb designed the Victoria and Albert Museum (built 1899–1909) and the Buckingham Palace main facade (1913). Westminster Cathedral (1895–1903) by J. F. Bentley is a fine neo-Byzantine building in red and white brick, with a tall campanile.

5. 20th Century.—In the 1920s and 1930s enormous buildings in an unadorned, massively simple style were built. Conspicuous examples are Imperial Chemical House, Millbank (1929–36), by Sir Frank Baines; London Transport Executive Headquarters, Westminster (1928–29), by Charles Holden; Broadcasting House (1930–31) by Val Myer; and the University of London Senate House (begun 1933) by Holden. In contrast are several of Sir Edwin Lutyens' finest buildings, including Britannic House, Finsbury Square (1920–23), and the Midland Bank, Poultry (1924–37).

But in the early 1930s a new trend appeared, derived from contemporary continental work. Buildings were constructed of reinforced concrete, with much use of cantilever construction to permit larger unbroken window areas, and without the masking screens of decoration hitherto considered indispensable; for example, Simpson's Store, Piccadilly (1936), by J. Emberton; Peter Jones's store, Sloane Square (1936), by W. Crabtree and Sir Charles Reilly; the two Highpoint blocks of flats, Highgate (1936 and 1938), by B. Lubetkin and Messrs. Tecton, and Dagenham Civic Centre by Barry Webber (1936). Battersea Power Station (1933) by Sir Giles Gilbert Scott is a functional design in brick.

Postwar building continued in this style. Among outstanding works are flats in Ranelagh Road (1946), by P. Powell and H. Moya; and the Royal Festival Hall, south bank, by R. H. Matthew and J. L. Martin. In the 1950s much of the war-damaged area of the City was rebuilt, and there and elsewhere in London office buildings several hundred feet in height were erected. These include Castrol House, Marylebone Road, by Gollins, Melvin Ward and partners (1958–59); New Zealand House, Haymarket, by R. H. Matthew and S. A. Johnson-Marshall (completed 1963); the 385-ft. (117-m.) Vickers House, Millbank, by Ronald Ward and partners (1959–62); and the Shell Centre on the south bank, by Sir Howard Robertson and partners, with a 351-ft. (107-m.)

tower (1957-62). Other notable buildings are Kensington Public Library by Vincent Harris (1957-60) and the Royal College of Obstetricians and Gynaecologists, by Louis de Soissons (completed 1960) in Regent's Park. A prominent landmark and London's tallest building, completed in 1965, is the 30-story Museum Radio Tower of the GPO off Tottenham Court Road; designed by the Ministry of Public Buildings and Works, it is essentially a concrete cylinder reinforced with concrete floors (up to 65 ft. [20 m.] in diameter) and rising to 620 ft. (190 m.) with a revolving restaurant at its top. (See also *Housing*, below.)

(K. Mn.; F. H. W. S.)

VI. CULTURAL AND RECREATIONAL FACILITIES

1. Museums, Art Galleries, and Libraries.—The origins of the British Museum in Bloomsbury go back to 1753 when the government purchased Sir Hans Sloane's Collection and the Harleian Manuscripts. The museum was opened in Montague House in 1759 and the present building was begun, immediately behind it, in 1823. The buildings, which now cover the site of Montague House, have undergone alterations and additions to the present day. The main collections are of prints, drawings, and manuscripts (including oriental); coins and medals; ethnography; and Egyptian, western Asiatic, oriental, Greek and Roman, British, and medieval antiquities.

The British Museum Library, the nation's largest, is a copy-right library and receives a free copy of every book printed in the United Kingdom. The huge round-domed reading room, where Karl Marx and other famous men have worked, was planned by Sir Anthony Panizzi (*q.v.*) and opened in 1857. Its Newspaper Library is at Colindale, near Hendon.

The British Museum (Natural History) in South Kensington was opened in 1881. It houses departments of zoology, entomology, paleontology, mineralogy, and botany. The Zoological Museum at Tring in Hertfordshire is a branch of this museum. Also in South Kensington is the Victoria and Albert Museum, which had its origins in material collected after the Great Exhibition in 1851. It houses a library and collections of sculpture, ceramics, engravings and illustration, paintings and drawings (including the Raphael cartoons and the John Constable Collection), metalwork, textiles (including European costumes), and woodwork, of all countries and periods, and also a section for the arts of India and Pakistan. Its subsidiaries include the Bethnal Green Museum (with a children's section) and the Wellington Museum at Apsley House by Hyde Park Corner.

Near the Victoria and Albert Museum are the Science Museum, with collections showing the development of the physical sciences and their practical application (*e.g.*, transport by land, sea, and air, mining, engineering, industrial machinery, tools, and chemistry, astronomy, and meteorology) and a large Library, and the adjacent Geological Museum. Also in Kensington (Holland Park) is the Commonwealth Institute (opened in 1962, formerly the Imperial Institute, founded in 1887) with a paraboloid copper-sheathed roof.

The London Museum, temporarily housed in Kensington Palace, and the Guildhall Museum cover between them every aspect of the archaeology, history, daily life, trades, and amusements of London. The London Museum also contains a collection of royal robes and the Guildhall Museum one of the clocks and watches belonging to the Clockmakers' Company. These two museums will eventually be amalgamated as the Museum of London and housed in a new building in the City at the west end of London Wall. Notable museums in south London are the Imperial War Museum in Lambeth Road; the National Maritime Museum at Greenwich; the Horniman Museum and Library, in Forest Hill, for the study of man and his environment, and with a large collection of musical instruments. The Geffrye Museum in Shoreditch contains mostly furniture, costume, and domestic items arranged in period rooms from 1600 to the present day. The many smaller museums include the Public Record Office Museum, four museums in the Royal Botanic Gardens at Kew, the Jewish Museum, and the Wellcome Historical Medical Museum.

Art galleries with permanent collections include the National

Gallery (1838), in Trafalgar Square, which contains European paintings of all schools and was founded in 1824; the adjoining National Portrait Gallery, founded in 1856; the Tate Gallery (British painting, modern French painting, and modern sculpture) at Millbank, opened in 1897 and built by the generosity of Sir Henry Tate, the sugar merchant; and the Dulwich College Gallery. The Wallace Collection in Hertford House (1776-78), Manchester Square, has paintings, sculpture, furniture, armour, ceramics, and other works of art bequeathed to the nation in 1897 by the widow of Sir Richard Wallace (*q.v.*). Sir John Soane's Museum in Lincoln's Inn Fields houses the founder's notable collection of works of art.

Of periodical art exhibition centres the most noteworthy is that of the Royal Academy of Arts in Burlington House, Piccadilly, which holds its main exhibition from the first Monday in May to the first Monday in August and a winter one of old masters or some particular nation's art. The Whitechapel Art Gallery was founded in 1900 for temporary exhibitions.

The London boroughs all maintain public libraries. Under a cooperation plan each borough specializes in certain groups of subjects in addition to its general stock. Considerable libraries, not all of them directly open to the public, are kept in certain ministries and government departments. The central library of the University of London supplements the libraries of the individual colleges. Most of the learned bodies and societies in London—*e.g.*, the Linnean Society, the Royal Geographical Society, and many others—house what is usually the best library for its subject in the country.

Membership libraries include the London Library in St. James's Square and the Dr. William's Library in Gordon Square. The National Central Library in Store Street is a national agency for interlibrary lending, and the Library Association has its headquarters in nearby Ridgmount Street. (See also **MUSEUMS AND GALLERIES**; **LIBRARY**: *Modern Libraries*.) (X.)

2. Ceremonial Events.—The London calendar is distinguished by many picturesque events and ceremonies, some of ancient origin. Among the best known are: (1) Trooping the Colour on the sovereign's official birthday (early June) by the Brigade of Guards on Horse Guards parade, behind Whitehall. (2) The state opening of Parliament by the sovereign, with a procession, generally in the second week of November. (3) The Lord Mayor's Show on the second Saturday of November, a ceremony probably originating in a 13th-century custom that the new lord mayor of the City must be confirmed by the ruling monarch or his justices; this is followed by (4) a banquet in the Guildhall to which more than 1,000 prominent guests are invited. (5) The annual opening of the Law Courts, about Oct. 1, with a procession through the main Hall of the Courts, preceded by a special service at Westminster Abbey. (6) The annual Royal Academy dinner, held on the Saturday before the opening of the summer exhibition. During the summer two or three (7) royal garden parties are usually held at Buckingham Palace.

Less distinguished, but extremely picturesque, annual events include (8) the Van Horse parade on Easter Monday and (9) the Cart Horse parade on Whitmonday, both in Regent's Park; (10) the sheep-dog trials in Hyde Park at the Whitsun weekend; (11) Doggett's Coat and Badge and (12) the University Boat Race Between Oxford and Cambridge on the Thames; (13) the Fairs on Easter Monday, Whitmonday, and August Bank Holiday on Hampstead Heath and Blackheath; (14) the Soho Fair, in July; and (15) the Chelsea Arts Ball on New Year's Eve. Daily ceremonies include (16) the Changing of the Guard at Buckingham Palace, which takes place every day the monarch is in residence; (17) the Mounting of the Guard of the Household Cavalry in Whitehall; and (18) the nightly locking up of the Tower of London, or Ceremony of the Keys, by the chief warden of the yeomen warders ("Beefeaters"), a part of the Yeomen of the Guard attached to the royal princes.

A telephone information service (Teletourist) provides details in English, French, Spanish, and German of important events being held in and around London on the day of the call. (P. G. H.)

3. Places of Entertainment.—London has about 40 theatres

presenting live entertainment in the West End and a few in the outer ring. The number fluctuates as some theatres may be used for motion pictures for extended periods. There are also several repertory theatres in the Greater London area and theatres where touring companies perform.

The theatrical centre in the 18th century grew from the Theatres Royal, Drury Lane, and Covent Garden (now the Royal Opera House), with the Queen's Theatre (variously known as the King's and His or Her Majesty's) and the Little Theatre, Haymarket (later the Theatre Royal), in the fashionable Pall Mall district. In the early 19th century theatres began to extend westward down the Strand, and with the construction of Shaftesbury Avenue in the 1880s this area became the principal theatrical artery. The National Theatre Company, formed in 1963, leased the Old Vic.

The outer ring theatres are within easy reach of the centre. They generally follow a definite policy: for example, the seasonal Open Air Theatre in Regent's Park specializes in Shakespeare and other poetic drama. There are several theatre clubs in the West End and a variety of cabarets, theatre restaurants, night clubs, and casinos. The exhibition halls of Olympia and Earls Court are also used for circuses, ice shows, and tournaments.

Other popular places of resort are Madame Tussaud's waxworks in the Marylebone Road, with an attached planetarium; and the Zoological Gardens in Regent's Park. Concerts are held in the Royal Festival Hall, south bank (capacity 3,266), and the Albert Hall, Kensington Gore (capacity 7,000), and recitals at the Wigmore and other halls. The National Film Theatre near the Royal Festival Hall shows classic films from all countries.

Places of entertainment are licensed by the Greater London Council, whose supervision includes inspection in respect of fire precautions and structural safety. Under the Theatres Act of 1843 the lord chamberlain grants licences for the performance of stage plays; his office is also responsible for censorship of plays and the British Board of Film Censors for that of films.

(RA. MA.; JO. MI.)

4. Parks and Open Spaces.—The parks and open spaces of Greater London are maintained by the crown (Royal Parks), by the Corporation of the City of London, by the GLC, and by the London boroughs. An important feature of the London area is the establishment of Green Belts around the perimeter of outer London.

St. James's and Green parks, Hyde Park, and Kensington Gardens stretch in an irregular belt for nearly 3 mi. between Whitehall and Kensington. Together with Regent's Park and Primrose Hill, Richmond Park, Greenwich Park, and Hampton Court and Bushy parks, they form what are called the Royal Parks.

St. James's Park (93 ac. [38 ha.]) was transformed from marshy land into a deer park, bowling green, and tennis court by Henry VIII, extended and laid out as a pleasure garden by Charles II, and rearranged by John Nash in 1827–29. Its lake, the broad Mall leading up to Buckingham Palace, and the proximity of the government buildings in Whitehall combine to beautify it. St. James's Park is continued between the Mall and Piccadilly by Green Park (49 ac. [20 ha.]).

Hyde Park, to the west, belonged originally to the manor of Hyde, which was attached to Westminster Abbey, but was taken by Henry VIII on the dissolution of the monasteries. James I opened it to the public after which Rotten Row became a fashionable promenade for horse riders (and is still used for riding). In 1908 the northeast corner of Hyde Park was cut to give additional accommodation for road traffic and the Marble Arch was left isolated. Hyde Park and Kensington Gardens (together 615 ac. [249 ha.]) between them contain a lake 1,500 yd. (1,372 m.) long known in its park portion as the Serpentine and in the gardens portion as the Long Water; from the bridge marking the division one of the finest prospects in London is seen, including the distant towers of Westminster and, on the north bank of the Serpentine, the bird sanctuary with Jacob Epstein's "Rima" memorial to William Henry Hudson.

In the 17th and 18th centuries Hyde Park was a favourite duelling ground, and for many years "Speakers' Corner" by Marble Arch has been the chief stamping ground of orators on social, re-

ligious, and other topics. Trafalgar Square is used for big organized political and other demonstrations.

Kensington Gardens, originally attached to Kensington Palace, were subsequently much extended; they are especially favoured by children, for the famous Round Pond is there, and in 1912 Sir George Frampton's statue of "Peter Pan" was placed near the west bank of the Long Water.

Regent's Park, mainly in Marylebone, owes its preservation to George IV, who, when regent, intended to build a palace there and had the park laid out by John Nash in 1812. With Primrose Hill, adjoining it to the north, it covers 464 ac. (188 ha.).

Other important Royal Parks are Greenwich Park (196.5 ac. [81 ha.]), with a magnificent view over the Thames; Richmond Park (2,469 ac. [999 ha.]), from whose higher parts can be seen the rich Thames Valley; and Bushy Park (1,100 ac.), which is noted for its horse chestnut trees. Wimbledon Common and Putney Heath, together covering 1,200 ac., lie in southwest London and are administered by Conservators of the River Thames.

The City of London administers small open spaces within its boundaries and also Highgate Wood, Queen's Park in Kilburn, and West Ham Park. Notable outlying spaces administered by the City are Epping Forest (6,000 ac.) in Essex, Coulsdon Commons (423 ac.) in Surrey, and Burnham Beeches (504 ac.) in Buckinghamshire. There is a wide variety of sports facilities in the parks, and summer entertainments are held in many of them.

The GLC has taken over responsibility for the former LCC parks and administers about 7,500 ac. Important open spaces are: in the northwest, the lofty Hampstead Heath, which with adjoining open spaces forms an unbroken stretch of 800 ac. (324 ha.) preserved to a great extent in its natural state; in the northeast, Victoria Park (217.5 ac.) and Hackney Marsh (343 ac.); in the southeast, Blackheath (270.5 ac.), Crystal Palace Park (199 ac.), where motor racing and open-air concerts are held and where in 1964 the National Recreation Centre was completed, and more than 750 ac. of heath and woodland around Shooters Hill and Abney Wood; in the southwest, Battersea Park (199.5 ac.) with its Festival Gardens and fun fair designed for the Festival of Britain in 1951. There is an extensive inner area where at most only small gardens and squares break the continuity of buildings, but in the 1950s and 1960s several hundred acres of open spaces were completed, many of which were in areas of great deficiency and represented first steps in the creation of new parks, e.g., that at North Camberwell (133 ac.). The GLC also owns Hainault Forest (1,108 ac.) in Essex.

The GLC provides a wide range of summer entertainments in its parks; about 1,600 shows range from symphony concerts to Punch and Judy.

In the mid-1960s plans were drawn up by 15 local authorities to develop the Lee Valley Regional Park (10,000 ac.) which would overlap into parts of Essex and Hertfordshire.

5. Sports Grounds.—Among many sports grounds, the two best-known cricket grounds are Lord's, near Regent's Park (Marylebone Cricket Club and Middlesex County matches, Oxford v. Cambridge university matches, Eton v. Harrow matches, etc.), and the Oval in Kennington (Surrey County matches, etc.). At these two grounds "test" matches are also played by teams representing England against overseas, mainly Commonwealth, sides. International and Oxford v. Cambridge Rugby football matches (among others) are played at Twickenham, and club Rugby is played at a number of grounds; and the final ties of the English Football Association Cup and of the Football Association Amateur Cup, and other international matches are played at Wembley Stadium. Several professional association football clubs are named after London districts, where they have their grounds. Athletic meetings take place at the White City (Hammersmith) and the lawn tennis championships at Wimbledon (Surrey). The Oxford v. Cambridge and men's international hockey matches are played at the Hurlingham Park Stadium (Fulham). In and around Greater London are horse racing courses (including Epsom, home of the Derby, and the Oaks) and greyhound tracks (including White City and Harringay, where horse shows are also held). Club golf is played and there are public courses. (X.)

GREATER LONDON, AS ESTABLISHED BY THE LONDON GOVERNMENT ACT 1963

VII. GOVERNMENT AND SERVICES

A. GOVERNMENT

1. 19th-Century Reforms.—From the time of the Municipal Corporations Act of 1835 London's government has developed differently from that of other cities. The ancient City of London has remained within its historic "square mile" and never extended its boundaries to incorporate adjacent urban areas, as did provincial cities such as Birmingham.

Apart from the City, metropolitan London was governed until the middle of the 19th century by a chaotic array of about 300 special authorities, responsible for such functions as street paving and lighting each in its own limited area. There were also a few bodies with wider jurisdiction, such as the Metropolitan Commissioners of Sewers. None of these, however, was responsible to the ratepayers.

In 1855 a Metropolitan Board of Works was established. Its members were elected by vestries set up one in each parish outside the City, the vestries in turn being elected by the parish ratepayers. The board's area of jurisdiction extended to 114 sq.mi. (295 sq.km.), which was wider than the built-up area of London at that time. One of its main functions was to complete and administer a proper system of main drainage, but it also carried out many other improvements, including the building of The Embankment, the establishment of the London Fire Brigade, and the acquisition of parks and open spaces (e.g., Hampstead Heath).

The Local Government Act of 1888 extended to the counties the municipal system of government by directly elected councils. The act also created a new County of London covering the area of the Metropolitan Board of Works and formed out of parts of the counties of Middlesex, Kent, and Surrey. Thus for the first time a directly elected body, the London County Council (LCC), became responsible for some major functions of civic government throughout the whole metropolis. The LCC was unique in being the only county council responsible for a wholly urban area. Its functions also differed in some ways from those of other county councils, although like them it later acquired many other responsibilities, notably in education and public welfare. For many years the

LCC met in the old offices of the Metropolitan Board of Works in Spring Gardens near Trafalgar Square; the County Hall was built on the south bank of the Thames and opened in 1922.

The 1888 act left the parish vestries and the City untouched, but the London Government Act of 1899 established in place of the vestries 28 metropolitan boroughs, each with a mayor, aldermen, and elected councilors. Among the functions which the boroughs had or acquired were the provision of housing and the maintenance of roads and streets.

2. The London Government Act 1963.—By the mid-20th century the built-up area of London had extended far beyond the boundaries of the LCC. By 1939 practically the whole of Middlesex, as well as parts of the Home Counties of Surrey, Kent, Essex, and Hertfordshire, formed with the County and the City of London a continuous urban area. Increasingly this growth drew attention to the question whether, at least for certain purposes such as traffic control, there should be a single authority for Greater London—i.e., an area of roughly 15 mi. (24 km.) radius from

Central London. A royal commission in 1921–23 concluded, though not unanimously, that no fundamental changes in London's government were needed. But because of their investigations an advisory committee for traffic matters was set up for a large area of the Home Counties, including Greater London.

During World War II problems of town and country planning assumed particular importance in relation to postwar reconstruction. There was a general recognition that the preparation and implementation of a development plan for Greater London could not easily be fitted into the existing pattern of local government because of the large number of different authorities involved. At the same time it was recognized that in any reform of local government London presented a separate problem. Thus, when in 1945 the Local Government Boundary Commission was appointed it was excluded from considering the County of London, and a separate body (the Reading Committee) was set up to examine the areas of the metropolitan boroughs and the distribution of functions between them and the LCC. But it was soon realized that these problems could be adequately considered only by looking at Greater London as a whole, and the committee was dissolved without making any recommendations. Finally, in 1957, after the government had reached agreement with the local authority associations on a review of boundaries and functions in other parts of the country, a royal commission was appointed to examine the working of local government in Greater London. In its report (October 1960) it made two main recommendations: (1) that there should be an elected council for the whole area of Greater London to administer those functions which could be effectively dealt with only over a wide area; (2) that for all other local government functions (except police and water supply, which were excluded from the commission's consideration) new boroughs should be created chiefly from amalgamations of existing local authorities.

The government accepted these recommendations but made some important changes in the London Government Act 1963. Under this act a Greater London Council (GLC) and 32 London borough councils were elected in 1964 and officially assumed their

responsibilities on April 1, 1965. The counties of London and Middlesex and many other local authorities were abolished, and border areas of Essex, Kent, Surrey, and Hertfordshire were incorporated into Greater London. The City of London retained its special position and constitution. The 1963 act created a unique form of government for London. The GLC is not a county council but a distinct type of local authority with special powers; the London boroughs were given powers similar to county boroughs in other parts of the country but with certain limitations.

3. The Greater London Council.—The GLC is responsible for an area of more than 600 sq.mi. (965 sq.km.) with a population of nearly 8,000,000, or about 17% of the entire population of England and Wales. Its main functions are: (1) planning (preparation of a master development plan, together with powers of planning control for more important proposals); (2) traffic and highways (traffic control including parking regulations and the power to introduce experimental traffic schemes, the upkeep of certain main roads designated "metropolitan roads," and the licensing of motor vehicles); (3) housing (it retains powers formerly held by the LCC to provide housing both inside and outside its area); (4) fire and ambulance services; (5) main sewers and refuse disposal; (6) licensing of theatres, betting tracks, etc. In addition, the GLC is responsible for education in the inner London boroughs (approximately the old LCC area), for a research and intelligence unit for London, and for the maintenance of certain historic and cultural buildings, parks, and open spaces.

In the first council elections (April 1964) 100 councilors were elected, electoral divisions being based on the London boroughs. Elections are held every three years, and after 1970 parliamentary constituencies will form the basis of electoral areas. The councilors elect a chairman and aldermen. The latter comprise one-sixth of the number of councilors and serve for six years. The vice-chairman of the council is by convention chosen from the majority political party, the deputy chairman from the minority party. The leader of the majority is known as leader of the council, the leader of the minority as leader of the opposition. These features are similar to those of the former LCC.

4. The London Boroughs.—These range in population from just under 150,000 to nearly 340,000, comparable with such provincial cities as Portsmouth, Nottingham, or Newcastle upon Tyne. There are in fact only six English cities with populations larger than that of Lambeth, the most populous London borough. Their powers are greater than those of the old metropolitan boroughs.

TABLE II.—London Boroughs

Boroughs	Area (in sq.mi.)	Population (mid-1965 est.)
City of London	1.0	4,600
Inner London boroughs		
City of Westminster	8.3	266,770
Camden	8.4	240,970
Islington	5.8	256,610
Hackney	7.5	253,810
Tower Hamlets	7.8	204,560
Greenwich	19.0	231,770
Lewisham	13.4	289,560
Southwark	11.5	308,460
Lambeth	10.5	339,560
Wandsworth	13.9	331,660
Hammersmith	6.2	215,240
Royal Borough of Kensington and Chelsea	4.6	216,810
Outer London boroughs		
Waltham Forest	15.3	241,400
Redbridge	21.8	247,960
Havering	46.3	250,430
Barking	13.9	172,970
Newham	14.5	260,070
Bexley	24.9	215,480
Bromley	61.3	301,450
Croydon	37.2	328,380
Sutton	16.7	166,790
Merton	14.6	185,130
Royal Borough of Kingston upon Thames	14.5	146,470
Richmond upon Thames	21.8	181,130
Hounslow	22.8	207,550
Hillingdon	42.6	233,020
Ealing	21.4	303,660
Brent	17.1	294,850
Harlow	19.6	209,600
Barnet	34.5	316,460
Haringey	11.7	256,750
Enfield	31.3	268,870
Total	621.7	7,948,800

The 20 outer London borough councils are the authorities in their areas for education and youth employment service; these services for the 12 inner London boroughs are the responsibility of the Inner London Education Authority, a special committee of the GLC. All 32 boroughs have responsibilities for health, welfare, and children's services, housing (except for overspill), and many other functions such as the provision of baths and libraries. They share with the GLC important powers in relation to roads and streets, planning, and the provision of parks and open spaces.

All the boroughs have received royal charters and elect mayors annually. Most have 60 elected councilors, although some have fewer. As in the GLC, aldermen comprise one-sixth of the number of councilors and are elected for six years.

For negotiation with central government departments and the LCC and for discussion of common problems, the former metropolitan boroughs established in 1912 a Standing Joint Committee. This was reconstituted in 1964 as the London Boroughs Committee with two representatives from each borough. The Metropolitan Boroughs Standing Joint Committee established in 1951 the first Organization and Methods service for local government. This has been reconstituted as a management services unit for the London boroughs with its own staff.

See also separate articles on the London boroughs.

5. The Corporation of the City of London.—The various changes that have taken place in London government did not affect the constitution or boundaries of the City of London. The City Corporation has the powers of a London borough with some additional authority, notably the control of its own police force. It also performs a number of local government functions the cost of which is borne not by the rates but by the City's corporate funds. These include the maintenance of markets such as Smithfield and Billingsgate, provision of open spaces for recreation (notably 9 sq.mi. of Epping Forest), and the upkeep of four Thames bridges, including London Bridge and Tower Bridge. The Corporation consists of a Lord Mayor, 25 aldermen, and 159 common councilmen. The election of common councilmen, a procedure dating from the 13th century, takes place annually. Aldermen are elected for life, and there is one for each ward of the City. The annual election of the lord mayor is by the Livery, a body whose members belong to the ancient trade guilds or livery companies.

6. Finance and Rating.—The London borough councils and the City of London Corporation each fix a general rate (local tax) annually to meet their own expenditure and that of other authorities whose services are provided in their area, particularly those provided by the GLC, the Metropolitan Police, and the Metropolitan Water Board. Rating valuation is based upon the annual rent which property might reasonably be expected to command. Apart from a few specific grants, the bulk of the central government's financial aid to local authorities is in the form of annual general grants. London boroughs (and the City) qualify for these grants which in the rest of England are paid to counties and county boroughs. After the London Government Act 1963 an inner London equalization scheme was instituted by which the general grants to the inner London boroughs were reallocated to help the poorer boroughs. For a transitional period until 1973 the GLC was required to meet part of the additional cost incurred by county councils affected by the reorganization of London government under the 1963 act.

7. Police and Fire Services.—Except for the City force, the police in London are not under the control of the local authorities as elsewhere in the country. The Metropolitan Police Force founded by Sir Robert Peel in 1829 and in the late 1960s numbering about 18,500, is under the direction of a commissioner responsible to the home secretary, who is the police authority. Its services include the special branch of the Criminal Investigation Department at New Scotland Yard. The boundary of the Metropolitan Police District in 1829 was a radius of approximately 15 mi. (24 km.) from Charing Cross and thus included what were at that time large tracts of open country. Only relatively minor adjustments were subsequently made to the boundaries, and the Metropolitan Police District formed the major part of the area examined by the royal commission in 1957. It now includes the whole of

Greater London together with some additional areas, mainly in Surrey and Hertfordshire.

Police costs are met jointly by central government grants and by contributions from local rates. The force operates in 23 divisions and there is also a patrol of river police. The City of London Force, formed in 1839 and with an establishment in the late 1960s of about 800, is under the direction of a commissioner appointed by the Common Council. (See SCOTLAND YARD.)

Traffic wardens are employed in London to assist the police in dealing with problems of parked vehicles.

The origins of a London fire service may be traced back to the parish fire engines and the brigade established by the fire insurance companies in the early 19th century. In 1866 the Metropolitan Fire Brigade (known after 1904 as the London Fire Brigade) was instituted by the Metropolitan Board of Works; it was taken over by the LCC in 1889. Until 1965 the remainder of Greater London outside the LCC area was served by brigades run by each Home County and county borough, with arrangements for mutual assistance. In 1965 the GLC assumed responsibility for the whole area and for the London Fire Brigade. An unusual feature of the brigade (dating from 1866) is that a small part of the cost is met by a statutory contribution from London fire insurance companies, which also maintain the London Salvage Corps to protect property from fire and water damage. The brigade is organized in three commands (Eastern, Northern, and Southern) with an establishment of over 6,500 firemen; it maintains more than 120 stations, including two river stations, and is equipped with numerous special appliances.

8. Parliamentary Representation.—At the 1966 general election there were 99 parliamentary constituencies in Greater London. Some constituencies overlapped the borough boundaries; e.g., the City was linked with the City of Westminster for parliamentary elections. Under proposals put forward in 1965 by the boundary commissioners their number would be reduced to 93 and the areas of most London boroughs would be divided into 3 constituencies; smaller boroughs, however, such as Hammersmith, would have only 2, and there would be 4 for large boroughs such as Barnet.

9. Administration of Justice.—The principal courts for the trial of criminal cases are the Central Criminal Court and the Courts of Quarter Sessions. The former, taking the place of the provincial assizes, sits at the Old Bailey and serves the whole of Greater London. There are five quarter sessions areas, of which that for inner London corresponds to the old LCC area and that for Middlesex to the areas of the eight London boroughs created from the former County of Middlesex.

In inner London the main courts of summary jurisdiction are the 13 metropolitan magistrates' courts, presided over by stipendiary magistrates, the chief magistrate's court being at Bow Street. In the City there are courts at the Mansion House and at the Guildhall.

County court districts are not related to local government areas. Coroners, except for the City, are appointed by the GLC. There are seven districts, each with a full-time coroner.

As in other parts of the country, prisons are the responsibility of the Home Office. Some of them have special features. For example, Brixton has accommodation for civil prisoners and Wormwood Scrubs has a surgical and psychiatric centre. Holloway is a women's prison.

10. Ecclesiastical Areas and Denominations.—The Church of England dioceses of London (north of the Thames) and Southwark (south) cover most of Greater London. The former includes the cities of London and Westminster. Diocesan cathedrals are St. Paul's in the City and St. Saviour's in Southwark. Small parts of Greater London come into the dioceses of Chelmsford, Rochester, Canterbury, St. Albans, and Guildford.

Westminster Cathedral near Victoria Station is the seat of the Roman Catholic primate of England; there is also a cathedral at Southwark, and these two sees cover most of Greater London, although a small part comes within the see of Brentwood in Essex.

The main centre of the Methodists is Central Hall near Parliament Square, Westminster, but Wesley's Chapel in City Road,

with John Wesley's tomb in its graveyard, is probably the best-known Methodist place of worship. Other well-known Nonconformist churches are the City Temple (Congregational), Holborn Circus; Bloomsbury Baptist Church, Shaftesbury Avenue; St. Columba's (Church of Scotland), Pont Street, Chelsea; and Friends' House, Euston Road. The international headquarters of the Salvation Army is in Queen Victoria Street in the City. The Great Synagogue of the Jews is in Adler Street off Whitechapel Road. There are also numerous foreign religious buildings, including the French Protestant Church in Soho Square, the Église Suisse in Endell Street, the Greek Orthodox Cathedral in Moscow Road, Bayswater, and Muslim mosques in Commercial Road and Park Road near Regent's Park. (G. R.H.)

B. EDUCATION

The Inner London Education Authority (ILEA), a special and virtually autonomous committee of the Greater London Council representing the 12 inner London boroughs and the City of London, took over responsibility for the education service of the LCC on April 1, 1965, when the 20 outer London councils also assumed responsibility as education authorities for their boroughs.

The continuity of service in the inner London area goes back to 1870, when the London School Board was set up under the Elementary Education Act of that year; the board developed elementary education over inner London without regard to internal boundaries, and had erected 469 schools by the time of its dissolution in 1904, when as a result of the Education (London) Act, 1903, its powers were transferred to the LCC. The LCC had the added responsibility of maintaining the voluntary schools, many of which had been built before 1870 by the British and Foreign School Society and the National Society. Other schools that provided higher education received grants, and the LCC, which (unlike the London School Board) had the power and later the duty to provide higher education, established a considerable number of secondary schools. The LCC's Education Committee also took over and developed the work of the Technical Education Board, established in 1893.

The London Government Act 1963 required that a report reviewing the special arrangements for education in inner London should be presented to Parliament in 1970, but in November 1965 the government proposed legislation to make the arrangements permanent and to dispense with this requirement. Of the 53 members of the ILEA, all of whom hold office for three years, 40 are members of the GLC elected by the local government electors for the 12 inner London boroughs and for the City of London. The other 13 consist of one representative of each of the 12 inner London borough councils and of the Common Council of the City. Since 1965, the ILEA has provided a full range of educational services. It maintains more than 1,250 primary and secondary (including nursery and special) schools catering for more than 400,000 pupils, and maintains or aids more than 100 colleges and institutes for about 390,000 students. There are 18,800 teachers (including part-time) and in addition 3,600 full-time and 16,000 part-time teachers are employed in further education. Nonteaching staff (full- and part-time) totals 35,000. There are also 1,900 primary and secondary schools with 625,000 pupils within the separate education systems maintained by the outer London boroughs.

The policy of the ILEA (following that of the LCC) and some of the outer London boroughs after their creation in 1965 was to establish a system of comprehensive schools providing all types of education. There are more than 70 of these in inner London and 2 in outer London, created either as new schools or by the amalgamation, enlargement, or reorganization of existing schools. A full range of five- and six-year courses is available. Many schools, including comprehensive, grammar, and other large schools, also offer seven-year courses. This applies to the ILEA boarding school for boys at Woolverstone Hall near Ipswich; tuition is free, but parents contribute to boarding costs according to their means.

1. Special Educational Treatment and Services.—There is an ILEA scheme for boys and girls in need of boarding education. A boarding house for 120 boys and girls at Crown Woods School,

Greenwich, gives priority to the children of servicemen stationed abroad.

Throughout Greater London pupils with disabilities are sometimes taught with normal children in ordinary schools. Children with handicaps that require special educational treatment are placed in day or boarding schools, or special classes, or independent schools. Provision is made for blind, deaf, physically handicapped, delicate, maladjusted, educationally subnormal, and autistic children, and for those with speech defects.

The youth employment services give vocational guidance and assist in finding suitable employment; advice is also given on further education and progress is reviewed after leaving school. The ILEA and outer London boroughs also work in partnership with voluntary youth organizations and provide recreational and youth centres for young people aged 14 to 20.

2. Further Education.—Courses are provided at technical and commercial colleges, schools of art, and polytechnics, and other colleges financially assisted by the authorities. Students are prepared for careers in science, technology, business, art, social sciences, and other fields, ranging from craft and technician courses to those for degrees, postgraduate qualifications, and research. Over 200,000 students attend the more than 50 colleges in inner London, and under a scheme for major awards and further education grants, financial help is given to many students taking university or other advanced studies.

Greater London has more than 20 colleges of education (formerly teacher's training colleges), 9 of which are maintained by the ILEA. A residential centre at Stoke D'Abernon in Surrey and a day centre in London provide courses for serving teachers; to meet the shortage of primary teachers they also provide short courses for eligible married women who have not taught for several years.

Evening institutes offer classes and activities on subjects such as arts and crafts, hobbies, physical activities, music, drama, literature, modern languages, and current affairs. Four colleges of advanced technology (Battersea, Brunel, Chelsea, Northampton) are to become technological universities, and three national colleges provide advanced training in specialized industries. For university education see LONDON UNIVERSITY.

3. Finance.—The ILEA decides how much should be raised for its expenditure by precepts made by the GLC on the rating authorities in inner London and how much by borrowing. The amount to be met from the rates is reduced by the general grant which is received not by the ILEA but by the inner London borough councils and the City Corporation. (Expenditure on education is the largest item taken into account when the total amount of general grant is fixed for the country as a whole.) During 1965–66 the ILEA's gross expenditure amounted to about £104,000,000. Nearly £11,000,000 of this, financed by borrowing, was spent on long-term assets. The other £93,000,000 was for revenue expenditure. Income from fees and charges, from other local authorities and from government grants amounted to about £17,000,000 and the net precept was £76,000,000.

The financial arrangements of the outer London boroughs follow the national (not the ILEA) pattern for local education authorities with expenditures met partly from rates (local taxes) and partly from central government grants.

4. Independent Schools.—There are many independent schools in Greater London ranging from small private schools to large schools of ancient foundation, such as Dulwich, St. Paul's, Westminster, and Harrow. There are also schools which receive grants directly from the Department of Education and Science. Other educational establishments provide training in art, commerce, law, medicine, music, and so on. (X.)

C. HEALTH AND WELFARE SERVICES

1. Environmental Health Services.—Main drainage for almost the whole of Greater London is the responsibility of the Greater London Council, the chief exception being that Bexley and Bromley boroughs are served by the West Kent Main Sewerage Board. The London boroughs are responsible for local street sewers and drains. As early as 1637 attempts were made to deal

with London's drainage problems, and the Fleet River was bridged over in that year. But effective main drainage dates from the time of the Metropolitan Board of Works (1856–88) and its successor the London County Council (1889–1965). The three main purification works are at Beckton and Crossness, which lie on the north and south banks of the Thames near Barking and Erith, and at Mogden near Isleworth in Hounslow. The GLC maintains five vessels to take sludge out to sea.

Collection of household refuse, rodent destruction, the provision of baths and washhouses, and the inspection of food, slaughterhouses, and offensive trades are all the responsibility of the London boroughs and the City of London. The GLC is liable for the disposal of refuse, usually by controlled dumping to reclaim waste land. The City of London is the port health authority.

Cemeteries and crematoria are provided by private organizations, by the London boroughs, and by the City of London, but no new cemetery can be established within Greater London without the approval of the Ministry of Housing and Local Government. The cemeteries have developed from the old parish burial grounds, but most of those now in use have been opened since the Burial Act of 1852. One of the largest municipal cemeteries is that maintained by the City of London at Manor Park (Newham), which covers more than 160 ac. (65 ha.). The first crematorium in London was opened privately at Golders Green in 1902, and the first municipal crematorium by the City at Manor Park in 1905. There are now 24 in Greater London, 16 of them municipally owned.

2. Hospitals.—Since 1948 all hospitals have been administered by the National Health Service (NHS). Greater London was for this purpose divided between 4 Regional Hospital Boards, each of which included a segment of inner London in its area as well as part of outer London and considerable areas outside. One reason for this division was that a large number of teaching hospitals (26) were in or near Central London, and regional hospital areas could not be focused, as in other parts of the country, on a single teaching hospital. Each teaching hospital has its own board of governors within the NHS. Until 1948 most of the teaching hospitals were private institutions, the Royal Hospital of St. Bartholomew, the oldest, having been founded by Rahere in 1123 and St. Thomas' in 1200. Many hospitals which were nationalized in 1948 were municipally owned, however, the LCC alone being responsible for about 100.

3. Personal Health and Welfare Services.—Responsibility for these is divided mainly among the NHS, local authorities, and voluntary agencies. The National Assistance Board, a government agency, may offer assistance in cash to those in need.

The services of doctors, dentists, and opticians are provided through executive councils of the NHS. There are three such councils within Greater London (Inner London, Middlesex, and North East London) and parts of Greater London are in the areas of the South East London and Kent and South West London and Surrey councils.

Local Authority Health and Welfare Services.—Apart from the ambulance service, which is run by the GLC, responsibility for these services lies with the London boroughs and the City. They cover a wide range of functions, including personal health services (maternity and child welfare, health visiting, home nursing); provision of residential accommodation for those in need of it, including the aged and the homeless; and the care of the physically and mentally handicapped in the community. The care of children deprived of a normal home life is also the responsibility of the London boroughs.

Voluntary Welfare Agencies.—These operate in parallel with the official services, and there are some special London organizations that have developed from religious and philanthropic work of the 18th and early 19th centuries. In 1869 the Charity Organization Society was founded to provide systematic help for those in need. Octavia Hill began her pioneer work in housing management in 1864 by acquiring houses in St. Marylebone. Later in the century came the settlements, of which the best known are Toynbee Hall (1884) in Stepney, Oxford House in Bethnal Green, and Cambridge House in Camberwell. The City Parochial

Foundation, founded from the charitable funds of the City parishes, has also done notable work. Altogether there are about 3,000 voluntary organizations in the metropolitan area.

Since World War II and the growth of publicly provided welfare services, the work of voluntary organizations has become increasingly concerned with problems of personal adjustment. This change was marked by the renaming in 1946 of the Charity Organization Society as the Family Welfare Association and the emergence of the Citizens' Advice Bureaux. There has also been a growth in organizations for the care of the aged and physically handicapped. Among other things the London Council of Social Service is concerned with the coordination of voluntary social work.

D. PUBLIC UTILITIES

1. Electricity.—After the introduction of electric lighting in 1881 at the Royal Exchange, a large number of electric light companies as well as some local authorities undertook to supply electricity. From 1926 until 1948 the London and Home Counties Joint Electrical Authority, with representatives of the county councils and the companies and the local authority undertakings, was responsible for supply over a wide area of southeast England, including the whole of Greater London. In 1948, when the industry was nationalized, the London Electricity Board became responsible for a large part of Greater London, but parts of the area are covered by the Eastern, South Eastern, and Southern Electricity boards.

2. Gas.—Gas lighting was introduced into the London streets early in the 19th century. In 1810 the Gas Light and Coke Company received a charter and remained in existence until nationalization in 1948, becoming one of the largest gas undertakings in the country. Other companies and some municipal undertakings also supplied gas. Since nationalization the North Thames Gas Board (with an area similar to that of the Gas Light and Coke Company) and the South-Eastern Gas Board have been mainly responsible for the supply in Greater London.

3. Water Supply.—In the Middle Ages London was supplied from local streams and wells such as Clerk's Well (Clerkenwell). Later, conduits and pipes were used and are recalled in street names such as Lamb's Conduit Street in Bloomsbury. In 1613 a plan put forward by Sir Hugh Myddleton to convey water from springs near Ware, Hertfordshire, to reservoirs at Clerkenwell through the New River was put into operation. Various companies were formed in different parts of London during the 18th and early 19th centuries, beginning with the Chelsea Water Company which opened its supply from the Thames in 1721. But it was not until 1902 that a comprehensive solution was found to the problem of supplying London with water. In that year the Metropolitan Water Board was constituted and took over eight existing water companies. The board is an indirectly elected authority with representatives of the various local authorities of the area which it supplies. Its area extends over 540 sq.mi. (1,399 sq.km.) and covers a large part of Greater London and some areas beyond, mainly in Hertfordshire and Kent. Most of the water supplied is taken from the Thames and Lea rivers. In 1962 the government proposed ultimately to transfer the powers of the Metropolitan Water Board to the Greater London Council. When this has been done it will bring London into line with other large cities, such as Liverpool and Manchester, that have long had a municipal water supply. Other undertakings supplying parts of Greater London include the South Essex and the South Suburban Water companies.

(G. R.H.)

E. HOUSING

Under the London Government Act 1963 the provision of municipal housing in the Greater London area became the responsibility of the GLC and the 32 London boroughs. The GLC inherited the housing powers of the former LCC, but under the act these would eventually be limited to the provision of housing for specific purposes, chiefly in relation to planning, comprehensive development, transport, and roads. The GLC also has powers, not extended to the London boroughs, to provide housing for the

overspill population outside Greater London.

Housing by the LCC began at the turn of the century, but it was not until the introduction of a central government housing subsidy in 1919 that the program fully developed. The period between World Wars I and II saw a new effort to provide homes to meet housing shortages and to replace slum dwellings. Among these interwar in-county cottage estates is the old Roehampton Estate in Wandsworth (1,212 dwellings), while Lilestone Estate in St. Marylebone (391 flats) illustrates the typical high-density slum clearance developments of that period. Extensive housing estates were built in areas then outside London but now in Greater London: Becontree (Essex) and St. Helier (Surrey) were examples of such interwar out-county development.

During World War II house building stopped; by 1945 London was suffering not only from the loss of five years of housing production but also from the extensive bombing which destroyed or damaged many thousands of homes. This period, however, had not been entirely wasted. An overall plan for the County of London was prepared in 1943 by Sir Patrick Abercrombie and J. H. Forshaw, and in 1945 a plan for Greater London, which covered the county and region round it, was prepared also by Abercrombie. These two plans, advisory only, have had great influence on the London region. The open-space proposals and the recommended housing densities have been very largely incorporated in the statutory Development Plan for London, prepared under the Town and Country Planning Acts, 1947–62. Proposals in the Abercrombie Plan for Greater London for the establishment of a firm Green Belt around the built-up perimeter areas and the supplementing of out-county LCC housing estates by New Towns (*q.v.*) were accepted by the government and served as a basis for the policy of the statutory Development Plans for the Home Counties.

The postwar house-building operations by the LCC can be divided into three main sections: the building of homes within the county; the completion of a restricted number of out-county estates already proposed before World War II started; and later the building of homes under the Town Development Act of 1952 which provides for the expansion of existing towns.

The LCC started its first major housing project in 1894 under the Housing of Working Classes Act, 1890, and by April 1965 when the council was abolished more than 200,000 homes had been completed. The major effort immediately after World War II was the building of homes in extensive out-county estates, where land acquisition had started or was proposed before the war, such as Debden (Essex) and Harold Hill. This out-county building program produced over 31,000 dwellings in seven years. Since 1950 the Architect's Department of the LCC, which has been retained by the GLC, set a standard of design and layout which has achieved international recognition. Before World War II, municipal housing was in general built either in cottage estates or estates of flats. The postwar trend in housing design has been for schemes of mixed development of flats and houses, using tall blocks of flats or maisonettes up to 24 stories, 4-story maisonettes, and 2-story houses.

One of the most outstanding examples of municipal housing designed with this approach is at Alton Estate, Roehampton, in southwest London. There more than 2,600 dwellings are provided in 11-story maisonette and flat blocks, 4-story maisonettes, 2-story family houses, and single-story old persons' houses which are set in nearly 130 ac. (53 ha.) of a landscaped site on the edge of Richmond Park. A population of approximately 9,600, with its own shops, schools, library, etc., has been housed on land which formerly comprised the extensive gardens of 18th-century country houses. Some of these fine houses have been retained and are being used for educational and social purposes.

The LCC also embarked on an ambitious program of urban renewal, particularly in the East End, where war damage, slum properties, and obsolete layout provided an opportunity for redevelopment. New houses, schools, factories, and roads and, most important, an extensive system of open spaces were developed in the Stepney-Poplar area. There at the Lansbury Estate and the Stifford Estate tall blocks of maisonettes rise from grassed open spaces to give panoramic views of the docks and the Thames.

Estates such as Quadrant in Islington, Brandon in Southwark, Silwood in Rotherhithe, and Warwick in Paddington are other examples of large-scale urban renewal projects.

The housing work done by the former metropolitan and county boroughs has also provided some fine architecture. Examples are Churchill Gardens Housing Estate, built for Westminster City Council; the Golden Lane Estate, built by the City of London; and certain developments by Camberwell Borough (now Southwark) Council. In outer London the redevelopment carried out by the West Ham County Borough (now Newham) Council in rebuilding one of the worst bombed areas in Greater London is noteworthy for its comprehensive approach.

Parts of Greater London are congested, and the demand on land and the need to replan obsolete areas with improved, more spacious living conditions means that many families are being accommodated outside the London perimeter. Some, but by no means all, of these are being settled in the eight New Towns around London. To this end the former LCC initiated many plans for the expansion of existing towns under the Town Development Act of 1952. Examples are at Haverhill (Suffolk), Thetford (Norfolk), Andover (Hampshire), Huntingdon (Huntingdon and Peterborough), and Basingstoke (Hampshire). The LCC also proposed the building of its own New Town in Hook, Hampshire.

In general, between 1945 and the mid-1960s the LCC provided more than 60,000 new dwellings inside the county and 45,000 out-county. Metropolitan boroughs provided about 70,000 new homes and private builders 20,000. Over the Greater London area, which included the former Middlesex County and certain other authorities, local councils built more than 310,000 homes during the same period, and private builders 140,000. Private building was restricted by licensing until 1952, after which it greatly increased. Examples of outstanding privately built estates are those at Ham Common, Blackheath, and Dulwich. The Ministry of Housing and Local Government approved a London housing program for 1965 to 1968, which gave target productions of 28,000 by the GLC and 97,000 by the London boroughs. (JA. WE.)

VIII. ECONOMIC ACTIVITIES

1. Industry.—London has always been the leading centre of manufacturing in Britain. In the late 1960s Greater London had a working population of more than 5,000,000, of whom nearly half were in manufacturing industries. The main types of industry, and of industrial area, are: (1) the old-established West End luxury industry (e.g., the bespoke tailors of Savile Row and the women's clothing area round Oxford Street); (2) the mass-production industry of the East End, producing mainly clothing (as in Whitechapel) and furniture (as in Shoreditch and Bethnal Green). A feature of both (1) and (2) is the prevalence of small workshops concentrated in industrial quarters with the advantages of ancillary services, labour supplies, and rapid dissemination of market trends. (3) Riverside heavy industry, dependent on imported materials (sugar refining, power stations, automobiles, shipyards); (4) the newer industries of outer London (as in Park Royal, along the Great West Road, and on the west side of the Lea Valley), which developed in 1918–39 for producing light, high-value goods, especially engineering, vehicles (including aircraft), and electrical products. Most of this last group represents outgrowths of (1) or (2) and since 1945 it has continued to expand rapidly both in outer London and beyond the Greater London boundary. London is also the centre of the British printing industry and motion-picture production.

2. Trade.—With New York and Rotterdam, London is one of the world's largest ports. Situated at the head of ocean navigation on the Thames Estuary, it is the chief exporting and importing centre of the United Kingdom, its exports amounting to more than one-third of the national total in value. The imports, mainly consumption goods for the London region, are, in order of value, tea, petroleum, wool, raw sugar, timber, butter, metals, and meat. Exports are mainly manufactured products.

The Port of London comprises 69 mi. (111 km.) of waterway, more than 2,000 ac. (809 ha.) of dock real estate, and 43 mi. (69 km.) of deep-water quays. There are five main groups of docks:

(1) the London and St. Katharine Docks, nearest the City, warehousing docks (tea, wool, wines, and spirits); (2) India and Millwall Docks, on the Isle of Dogs (sugar, fruit, grain, hardwood); (3) Surrey Commercial Docks, on the south bank (timber); (4) the Royal Docks opposite Woolwich (Royal Victoria, Royal Albert, King George V), large-capacity import docks (tobacco and meat); (5) Tilbury (q.v.), 26 mi. (42 km.) downstream from London Bridge, bulk docks for transit upstream, without warehouses; the passenger terminal with floating passenger landing stage and great dry dock. Since 1909 the docks have been managed by the Port of London Authority (PLA), comprising representatives of government departments, the City Corporation, the GLC (formerly the LCC), Trinity House, traders, and workers. Outside PLA management are the private wharves lining the river downstream from London Bridge.

3. Commerce.—London's commercial activities are concentrated in the City and stem directly from the importance of the port in international trade. The London Chamber of Commerce is there. With New York and Zürich, London is one of the great financial centres of the world. Its financial institutions, which mostly date from the late 17th and early 18th centuries, include the Bank of England; the English clearing banks, 8 out of 11 of which have their headquarters in the City; the London offices of foreign and Commonwealth banks; the merchant banks for international borrowing; specialized financial institutions including discount houses, stockbrokers, insurance companies, including Lloyd's, the great marine underwriters; and the Stock Exchange. The City also contains great commodity exchanges: the Baltic Exchange (grain, seeds, vegetable oils, shipping) and the London Commodity Exchange (cocoa, coffee, sugar, rubber, etc.), as well as specialized exchanges for wool and metals. (See BALTIC, THE; BANK OF ENGLAND; LLOYD'S; STOCK EXCHANGE: Great Britain.)

Much of the fresh food consumed by Londoners comes through wholesale markets situated mainly on or just beyond the edge of the City: Billingsgate (fish), on the waterfront; Smithfield (meat), at the northern edge of the City; Covent Garden, the great fruit, vegetable, and flower market, on the west (scheduled to be moved to a Nine Elms site in southwest London by the early 1970s); Spitalfields, a subsidiary fruit, vegetable, and flower market, on the east; and Leadenhall (poultry) on the southeast. (See also BILLINGSGATE; COVENT GARDEN; SMITHFIELD; SPITALFIELDS.)

IX. COMMUNICATIONS

1. River.—The primary importance of the river as a highway is to the port, although upstream of London Bridge it is used by barge traffic to Teddington, where the lowest Thames lock is, and to Kingston upon Thames. Summer launch services run from Westminster upstream to Kew, Richmond, and Hampton Court and downstream to Tower Bridge, Greenwich, and the docks; steamers from Tower Pier take excursionists to Southend, Essex; but otherwise the river is chiefly important as a barrier.

2. Roads.—Main roads in London are of five kinds: (1) Roman roads, many of which are followed by modern highways; they include Watling Street (q.v.), northwest by Edgware Road; Ermine Street (q.v.), north by Kingsland Road; Stane Street, to Chichester (Sussex) by Clapham Road; the Silchester Road, by Bayswater Road; (2) old field ways linked up to make modern highways, e.g., Harrow Road; these, narrow and twisting, cause some of London's worst traffic problems; (3) former turnpikes of the 18th or 19th century, then just outside the built-up area; these included some new roads, e.g., Finchley Road, built 1826–30 as a direct road from the West End to the north, bypassing Islington and Highgate; (4) streets cut through central London in the 19th century as part of slum clearance schemes; the model was John Nash's Regent Street (begun 1813), and later roads of this kind include New Oxford Street, Clerkenwell Road, Farringdon Road, Charing Cross Road, Shaftesbury Avenue, the Thames embankment, and Victoria Street; (5) arterial roads built 1918–39 in the outer parts of the conurbation; they include such major works as the Great West Road, North Circular Road, and Kingston Bypass. After 1950 the Cromwell Road was extended through

Hammersmith to Chiswick, with new flyovers (overpasses) at both these places; the improvement was completed in 1962. Traffic congestion in inner London, already serious enough in 1905 to merit study by a royal commission, increased enormously with the growth of private motoring.

During 1960 the government announced an accelerated program of urban road construction, under which an average of £10,000,000 a year would be allocated to improvements in the County of (now inner) London. The most important projects of the 1960s include: the Park Lane improvement (completed 1962), including the construction of an east-west underpass at Hyde Park Corner and the conversion of Park Lane and the East Carriage Drive to complementary dual carriageways (four-lane highways); the underpass between Kingsway and Waterloo Bridge north approach, under the Strand (completed 1964); the underpass between Victoria Embankment and Upper Thames Street, under Blackfriars Bridge; the underpass for Euston Road under Tottenham Court Road; new junctions on roundabout principles at Holborn near Kingsway, St. Giles' Circus, and Elephant and Castle; duplication of Blackwall Tunnel to provide one-way flow in each tunnel; extension of Western Avenue on motorway (M) principles to Paddington, with flyover across Edgware Road to Marylebone Road; a new north-south link on motorway principles across west London from Western Avenue extension to a new Thames bridge near Wandsworth; comprehensive improvement of the Dover Road, on motorway principles, with a spur to Blackwall Tunnel.

Plans were made for radial motorways from Chiswick to London Airport and the west (M4, completed 1965); from Hendon to the Birmingham Motorway (M1); from Leyton to Bishop's Stortford (M11); from south London to Crawley, for Brighton (M23); and from Sunbury-on-Thames to Basingstoke (M3).

Public road transport is provided exclusively by more than 8,000 red and green diesel buses of the London Transport Board (LTB) and by taxicabs. The London General Omnibus Company, founded in 1855, became the principal operator. It replaced horse buses by motor buses between 1905 and 1911, amalgamated with the underground railways in 1915, and in 1933 passed under control of a public authority, the London Passenger Transport Board. In 1948, on the nationalization of the main line railways, this became the London Transport Executive of the British Transport Commission. In 1962, on the abolition of the commission, the executive became the London Transport Board. Buses replaced the remaining tramcars in 1952 and the remaining trolley buses in 1962. The LTB operates all scheduled passenger services within a 2,000 sq.mi. (5,180 sq.km.) region of average radius 25 mi. (40 km.) from Charing Cross. In the outer parts of this region the LTB operates "country" buses (green), and across the region run the express long-distance Green Line Coach services, introduced in 1930. About 6,000 diesel taxicabs licensed by the Metropolitan Police are operated by companies or owner-drivers. Smaller taxicabs (minicabs) must be prebooked and may not ply for hire.

3. Railways.—London's first railway was the London and Greenwich (1836). Most early lines (London and Birmingham 1837; Great Western 1838) were trunk lines, and suburban traffic developed tardily. When it did, it focused primarily on City termini: e.g., the London, Brighton, and South Coast to London Bridge; the North London, to Broad Street. From the 1860s certain lines were compelled to run cheap workmen's trains at very low fares; this brought about the development of workers' suburbs in Tottenham and Walthamstow by 1900. After nationalization of the railways in 1948, King's Cross, Liverpool Street, Marylebone (since 1959 wholly a London Midland Region station), and Fenchurch Street stations had headquarters offices for the Eastern Region; Waterloo, Charing Cross, London Bridge, and Victoria for the Southern Region; Euston for the London Midland Region, with departments at St. Pancras, Broad Street, and Marylebone; and Paddington for the Western Region.

Parliament did not allow the main lines to enter Central London, stipulating that the termini should be connected by underground lines. The first such railway, the Metropolitan, opened under steam operation in 1863 between Paddington, Euston, King's Cross, and Farringdon Street; it was extended progressively to form an

inner circle in 1884, the system being electrified in 1905.

A separate underground network peculiar to London is the system of deep-level "tube" railways whose construction was facilitated by the underlying London clay, which runs at a depth of about 50–100 ft. (15–30 m.) and reaches 181 ft. at Hampstead. The first tube railway, the City and South London between King William Street and Stockwell, was opened in 1890; by 1907 the network of lines under Central London was complete. These early tubes were almost wholly within the built-up area, but between 1924 and 1939 they were extended above ground into the open country, thus encouraging suburban expansion on an enormous scale. By 1939 the tube system extended to Uxbridge on the west, to Stanmore and Edgware on the north, and to Morden on the south, a radial distance of 10–15 mi. (16–24 km.) A new tube between Victoria and Walthamstow was to be completed in the late 1960s. (See also SUBWAY [UNDERGROUND RAILWAY]; *The London Transport System*.)

South of the river the suburban services of the main-line railways were increasingly electrified from 1909; most of those of the Southern Railway were electrified between 1925 and 1930, and in 1933–38 express lines to the coast (Brighton, Portsmouth) were electrified, encouraging long-distance commuting. The London Midland Region electrification scheme linking Euston with Manchester and Liverpool was completed in 1966. Suburban electrification north and east of London followed World War II. The electric underground and suburban trains operate about 250 mi. (400 km.) of railway.

4. Commuting.—In 1962, about 1,238,000 persons entered Central London each workday morning between 7 and 10 A.M. Whereas in 1905 three-quarters of the commuters were bound for the City, by the 1960s about half went to the West End. About 545,000 came by underground railways, 473,000 by surface railways, 215,000 by bus, and 123,000 by private transport, including 94,000 people in 64,000 automobiles. Thus over 90% came by public transport. A major problem was the great congestion in the peak hour. Attempts to meet the problem by the staggering of working hours met with only limited success.

5. Air Transport.—London Airport, at Heathrow, 15 mi. W of Central London, is one of the largest and busiest in Europe, with traffic that increased from 2,634,000 passengers annually in 1955 to more than 9,500,000 in the late 1960s. As a result an increasing amount of traffic (about 1,000,000 annually) was diverted to Gatwick Airport, 27 mi. (43 km.) S of London. In 1964 a proposal was made to supplement these airports by one at Stansted, 34 mi. (55 km.) N of London. A privately owned helicopter terminal (Heliport) was opened in 1959 on the south bank of the Thames.

6. Post, Telecommunications, Radio, etc.—The post office dates from an act of 1657; it still occupies its traditional headquarters in St. Martin's-le-Grand on the northwestern edge of the City. For rapid distribution of mail, a post-office underground railway crosses Central London from Paddington to Whitechapel, with intermediate stops at the main sorting offices. The headquarters of the General Post Office telecommunications system are in London. The overseas telegraph, telephone, and telex services are operated from London where there are international centres. The Post Office Tower provides microwave radio links for carrying long-distance telephone and television circuits.

Broadcasting House, close to All Souls' Church, Langham Place, is the headquarters of the British Broadcasting Corporation, which has its television centre at Sherlocks Bush. The Independent Television Authority has its headquarters in Brompton Road and programs are transmitted from Beulah Heights, Croydon. The national newspaper offices are in and around Fleet Street.

LONDON, CONFERENCES OF. Many important international conferences have been held in London during the 19th and 20th centuries. The first, in June 1814, was the outcome of the visit of the Allied sovereigns to the prince regent after the downfall of Napoleon, the opportunity being used to effect some of the settlements agreed upon in the first treaty of Paris, notably the conditions attached to the erection of the kingdom of the United Netherlands. From 1815 onward, too, diplomatists of the Allies accredited to Great Britain formed a conference in London for the purpose of discussing measures for the suppression of the slave trade and of the Barbary pirates.

Greece.—In 1827 a conference met in London to attempt to settle the affairs of Greece. This conference (the first international gathering to be usually thus described) met on July 12, 1827, and sat till 1832. It was attended only by the representatives of the three powers which had signed the treaty of London (July 6, 1827); i.e., France, Great Britain and Russia. The treaty of London of May 7, 1832, however, which established the kingdom of Greece, with Prince Otto of Bavaria as king, was signed also by Baron de Cetto on behalf of the king of Bavaria.

Belgium.—In 1830, while this conference was still in session, the insurrection of the Belgians against the king of the Nether-

lands led to the summoning of another conference in London which first met on Nov. 4, 1830, there being in all 70 sessions. After the independence of Belgium had been recognized and Leopold of Coburg had been elected king (June 4, 1831) a Belgian plenipotentiary was also admitted. On Oct. 1, 1832, Austria, Prussia and Russia having refused to agree to the French proposal to coerce the Dutch king into accepting the 24 articles embodied in the treaty of Nov. 15, 1831, the conference virtually broke up, the further proceedings being conducted by the representatives of France and Great Britain. These ended on May 21, 1833, with the signature of a convention between the two powers and the Netherlands, providing for the nonrenewal of hostilities and freedom of navigation on the Scheldt and Meuse. Thus matters remained till 1839 when, the king of the Netherlands having at last consented to recognize the inevitable, the plenipotentiaries of all the five powers met in London to sign with those of the Netherlands, on April 7-19, a treaty to which the 24 articles of Nov. 15, 1831, were annexed (see BELGIUM).

Schleswig-Holstein and Luxembourg.—In 1848 the war between Prussia and Denmark over the Schleswig-Holstein question (q.v.) led to the assembling of an international conference in London. It met after the pressure of the powers had forced Prussia to conclude the truce of Malmö (Aug. 26) and resulted in the peace signed at Berlin on July 2, 1850, which left the main problems unsolved. By the protocol signed on May 8, 1852, the conference settled the succession to the Danish throne and the duchies of Schleswig and Holstein on Christian of Glücksburg.

In 1864, during the war between the two great German powers and Denmark, Great Britain invited the signatories of the protocol of 1852 to a conference in London, with a view to a settlement. The conference met on April 25, immediately after the storming of the Düppel lines; but, as a result of Bismarck's diplomacy, it broke up on June 25 without having effected anything.

In 1867 an important international conference met in London, at the instance of the king of the Netherlands, to deal with the situation in regard to Luxembourg created by the war of 1866 and the consequent dissolution of the old German confederation. The conference consisted primarily of the representatives of the states signatory of the treaty of 1839, by which the status of the grand duchy of Luxembourg had been determined (i.e., Austria, Belgium, France, Great Britain, Holland-Luxembourg, Prussia and Russia), but on the motion of Lord Stanley, who presided, the Italian ambassador was also invited to assist. The conference resulted in the treaty of London of May 11, 1867, by the terms of which the Prussian troops, which had garrisoned the city of Luxembourg since 1815, were to be withdrawn and the fortress demolished. On the motion of the Prussian plenipotentiary, Count Bernstorff, the signatories guaranteed Luxembourg's neutrality.

Russia.—In 1871, during the Franco-German War, the denunciation by Russia of the Black Sea clauses of the treaty of Paris of 1856 led to the assembling of a conference in London in order to regularize the situation thus created by a revision of the treaty of 1856, so far as regarded the neutralization of the Black sea, the straits of the Dardanelles and Bosphorus, and the navigation of the Danube. The conference, which sat from January to March and was attended by the representatives of North Germany, Austria-Hungary, Great Britain, Italy, Russia and Turkey, while revising the treaty in accordance with Russia's wishes, asserted the principle of the inviolability of treaties (see TREATY).

Treaty of Berlin.—In 1883 a conference sat in London (Feb. 8-March 10) to consider the execution of articles 54 and 55 of the treaty of Berlin of July 13, 1878, concerning the navigation of the Danube (q.v.). It was attended by representatives of all the powers which had signed the Berlin treaty and those of the other riverain states (i.e., Serbia and Rumania) which had not signed the treaty were invited to attend but without a deliberative voice. Bulgaria, as a vassal state, was represented by the Turkish delegate. Rumania refused to accept these conditions, but the Serbian plenipotentiary attended the sessions.

Egypt.—In 1885 a conference between the great powers and Turkey was held in London to deal with the situation arising out of the financial crisis in Egypt. The result was the signature of

March of what is known as the London convention, the terms of which were embodied in a khedivial decree and, with some modifications, remained for 20 years the organic law governing the administration of the finances of Egypt (*see EGYPT: History: Modern Period*).

Naval Conference.—In 1908, at the invitation of the British government an international naval conference met in London to attempt a settlement of those questions regarding contraband, blockade, etc., which had been raised at the second Hague conference. The conference met on Dec. 4, 1908 and continued in session until Feb. 26, 1909, the outcome of its labours being the Declaration of London. This declaration was never ratified.

The Balkans.—In 1912 and 1913 conferences were held in London to arrange terms of peace between Turkey and the allied Balkan states, Bulgaria, Greece, Montenegro and Serbia. The conference, which was attended by representatives of the belligerent states, was opened on Dec. 16, 1912, by the British foreign secretary but was suspended without result on Jan. 6. It met again on May 30, 1913, the outcome being the treaty of London signed on the same day. The conference was dissolved on June 9, and its work was rendered abortive by the outbreak, immediately afterward, of the Second Balkan War (*see BALKAN WARS*).

Conferences After World War I.—In 1921–22 four conferences of Allied statesmen were held in London, to adjust matters arising out of the peace treaties which ended World War I. The first met from Feb. 21 to March 14, 1921, and carried on alternately two sets of negotiations, one with the Athens, Constantinople and Ankara governments on the near eastern question (*see TURKEY*), the other with Germany on the subject of reparations. The result in both cases was failure. The conference was hardly over before the Greeks launched a new offensive against the Turkish Nationalists, while the unacceptable German counterproposals led, early in March, to fresh sanctions being taken against Germany (occupation of Düsseldorf, etc.).

On April 29 the Allied leaders met again in London, having before them the Reparations commission's estimate of Germany's total liability. They made this the basis of a schedule of payments which was sent to Berlin on May 5, with an ultimatum, and on the 11th the German government accepted the Allies' terms.

In 1922 as a result of the failure of Germany to carry out this agreement, similar conferences of Allied leaders met in London, in August and in December. At each of these R. Poincaré put forward his claim for "productive guarantees" from Germany as a precondition of any moratorium. The British could not agree to such sweeping measures and the conference adjourned on Dec. 11 without agreement being reached (*see REPARATIONS*).

In Jan. 1930 the United States, France, Italy and Japan, accepting a British invitation, met in London to discuss naval disarmament. By the end of three months general agreement had been secured on the regulation of submarine warfare and a five years' holiday for capital ship construction. The United States, Great Britain and Japan signed, on April 22, a treaty limiting battleship tonnage in the ratios of 10:10:7. France and Italy, opposed respectively to the concept of ratios and the acceptance of any inequality, declined to sign (*see DISARMAMENT*).

On June 12, 1933, the World Economic conference met in London, with representatives of the U.S. and all the League of Nations states in attendance. Soon after it opened, the announcement by Pres. Franklin D. Roosevelt of his opposition to currency stabilization rendered its proceedings nugatory, and on July 27 it adjourned with nothing accomplished.

Conferences After World War II.—On Jan. 10, 1946, the first part of the first session of the United Nations assembly met in London at the Central hall, Westminster. It was principally notable for the election of Trygve Lie as secretary-general and the bringing into operation of the Security council and the Economic and Social council.

After the failure of the French assembly to accept the European Defense community plan a nine-power conference was hurriedly summoned to meet in London on Sept. 28, 1954. The foreign ministers of Great Britain, the United States, Italy, Belgium, the Netherlands and Canada and the prime ministers of

France, the Federal Republic of Germany and Luxembourg were present. The agreements which they signed on Oct. 3 provided for the termination of the occupation regime in western Germany, the establishment of an agency to control continental armaments, and the admission of Germany and Italy to the Brussels Treaty organization and of Germany to the North Atlantic Treaty organization (*q.v.*). Britain undertook to maintain four divisions on the continent for 44 years and the Federal Republic of Germany pledged itself not to seek German reunification by force.

In 1956 the nationalization of the Suez canal by the Egyptian government created an urgent problem for all the canal users. At the invitation of Britain, France and the United States a conference of 22 countries met in London during Aug. 16–23. Eighteen countries agreed on a plan to guarantee free use of the canal. This was rejected by Egypt, and a second London conference (Sept. 19–21) proposed the establishment of a canal users association. The association, imperfectly conceived and inadequately directed, failed to materialize and in October the Israeli attack on Egypt and the Anglo-French armed intervention in Suez gave events an entirely different turn.

LONDONDERRY, EARLS AND MARQUESSES OF.

The title of earl of Londonderry was first created for THOMAS RIDGEWAY (*c.* 1565–1631), a Devon man, who was treasurer in Ireland from 1606 to 1616 and was engaged in the settlement of Ulster. Ridgeway was knighted in 1600, made a baronet in 1611, Baron Ridgeway in 1616 and earl of Londonderry in 1622. His great-grandson ROBERT, 4th earl, died without male issue in March 1714, when the earldom became extinct. Robert's son-in-law, THOMAS PITT (*c.* 1688–1729), son of Thomas "Diamond" Pitt (1653–1726) and uncle of the great earl of Chatham, was created earl of Londonderry in 1726, but the earldom again became extinct when his younger son RIDGEWAY, 3rd earl of this line, died unmarried in Jan. 1765.

In 1796 ROBERT STEWART (1739–1821), of Mount Stewart, County Down, was made earl of Londonderry in the Irish peerage. He had been created Baron Londonderry in 1789 and Viscount Castlereagh in 1795; in 1816 he was advanced to the rank of marquess of Londonderry. His son by his first marriage, ROBERT (1769–1822), 2nd marquess, is best known as Viscount Castlereagh, foreign secretary from 1812 to 1822 (*see LONDONDERRY, ROBERT STEWART, 2nd Marquess of*). He was succeeded by his half brother, Charles William Stewart, 3rd marquess, who in 1819 married as his second wife the daughter and heiress of Sir Henry Vane-Tempest and changed his surname to Vane. The 5th and 6th marquesses made further changes to the family name, which became in 1885 Vane-Tempest-Stewart.

CHARLES STEWART HENRY VANE-TEMPEST-STEWART (1878–1949), 7th marquess, was member of parliament for Maidstone from 1906 to 1915, undersecretary for air (1920–21) and minister of education for Northern Ireland (1921–26). As secretary of state for air (1931–35), he was criticized first because of the extent to which his caution obstructed progress at the Geneva disarmament conference toward the abolition of bomber aircraft, and later, after Hitler's extravagant claims (1935) for the German air force, because of British weakness. He defended his policy in *Wings of Destiny* (1943). He died in Northern Ireland on Feb. 11, 1949. His grandson, ALEXANDER (1937–), 9th marquess, succeeded to the title in 1955.

LONDONDERRY, ROBERT STEWART, 2ND MARQUESS OF (1769–1822), better known as VISCOUNT CASTLEREAGH, statesman and diplomatist responsible for British policy in the peace settlement at the close of the Napoleonic Wars, was born in Dublin on June 18, 1769. His father, Robert Stewart (*d.* 1821), was a landowner of Donegal and County Down who, largely through successive marriages with daughters of Lord Hertford and Lord Camden, was elevated to the peerage in 1789, promoted earl (1796) and finally marquess of Londonderry in 1816. Robert, his eldest surviving son by his first wife (Lady Sarah Frances Seymour-Conway), known from 1796 to 1821 by the courtesy title of Viscount Castlereagh, was educated at Armagh and St. John's college,

Cambridge. He was elected to the Irish parliament of 1790 as an independent member. In 1794 he married Amelia Anne Hobart (d. 1829), daughter of the earl of Buckinghamshire, a beautiful if slightly eccentric woman to whom he remained devotedly attached throughout their long and childless marriage. In 1797 he was appointed keeper of the privy seal (Ireland) by his relative, Earl Camden, then lord lieutenant of Ireland, and from March 1798 served him as acting chief secretary. He was formally appointed to that office in Nov. 1798 by the next lord lieutenant, the marquess Cornwallis.

Castlereagh's tenure of office in Ireland coincided with the two most important events of Irish history in the late 18th century: the 1798 rebellion and the union with Great Britain. While taking active and successful measures to quell the revolt in 1798, Castlereagh shared the view of Cornwallis that a policy of clemency was essential to end the disturbances. At the same time the rebellion showed the need for drastic changes in the Irish constitution. The threat of French invasion and the 1798 rebellion convinced Castlereagh of the need for a union with Britain; and it was to assist Cornwallis in promoting this measure that he was appointed chief secretary. The operation was difficult and sordid; it was only by tact and persistence, backed by systematic bribery, that the executive finally carried the Union act through the Dublin parliament in June 1800. Its passage provided the first great demonstration of Castlereagh's qualities; and his singlehanded leadership of the Irish commons against the massed oratorical talent of the Irish Protestant opposition was the start of his political reputation. The bitter resistance confirmed his view that the issues of union and Catholic emancipation must be separated if either was to be achieved; but as soon as the union was accomplished, he urged the early settlement of the Catholic question. In Feb. 1801, when Pitt left office on his failure to obtain George III's consent to emancipation, Cornwallis and Castlereagh at once sent in their resignations, consenting to serve, however, until their successors could take over.

Secretary for War (1805-09).—Though out of office after May 1801 Castlereagh continued to advise Henry Addington's ministry on Irish questions, and in July 1802 he was appointed president of the board of control responsible for Indian affairs. His energy and intellectual powers gained him an immediate influence in the cabinet and after Pitt's return as prime minister (May 1804) he also took over in July 1805 the duties of secretary for war. His first important task, the dispatch of a British expeditionary force to Hanover, was rendered ineffectual by Napoleon's victory at Austerlitz (Dec. 1805); but it convinced Castlereagh of the strategic value of the British army in continental warfare, and he urged the organization of a permanent force of 60,000 men to serve in any suitable theatre of war. On Pitt's death in Jan. 1806 he left office and became the chief opposition spokesman on foreign and military affairs. He returned to the war department in the duke of Portland's ministry in April 1807, and successive projects for an expedition to the Baltic (partly frustrated by Russia's alliance with France in the treaty of Tilsit of July 1807) and to South America (to detach the Spanish colonies from French-occupied Spain) showed his determination to engage in major warfare against a continent now completely dominated by Napoleon. The adoption in 1808 of his plan for reorganizing the regular, reserve and militia forces provided the country with adequate home defenses and a larger and more efficient army for overseas operations. When the Spanish revolt broke out the same year, the decision was at once taken to send a major expedition to the peninsula. Castlereagh failed, because of the claims of seniority, to get Sir Arthur Wellesley (later duke of Wellington) as supreme commander, but after the death of Sir John Moore at Corunna in Jan. 1809, he secured the cabinet's consent to the continued defense of Portugal under Wellesley.

Castlereagh now planned an operation against Napoleon's central naval base at Antwerp, which would also influence north Germany in favour of the allies fighting in central Europe. Cabinet procrastination delayed the expedition until the battle of Wagram (July 1809) forced Austria to make peace, and the cautious tactics followed by the commander, the earl of Chatham, contrary to

Castlereagh's instructions, allowed the force to waste away of disease on the island of Walcheren. The disaster brought to a head the long-standing divisions and intrigues in the cabinet. Since March 1809, George Canning, the foreign secretary, had been pressing for a change of policy and even before the Walcheren expedition he had secured secret agreement to the replacement of Castlereagh by the marquess Wellesley. When, in September, Castlereagh eventually learned of the ignominious position in which he had been left, he attributed the whole blame to Canning. The two men fought a duel (Sept. 21) and subsequently resigned office. Portland also retired, and though Spencer Perceval patched up the weakened cabinet, Castlereagh remained out of office for the next two and a half years.

Foreign Secretary (1812-22).—In March 1812 he rejoined the government as secretary for foreign affairs. After Perceval's assassination in May 1812 he offered to transfer to the exchequer to facilitate the adhesion of Canning, but negotiations broke down on Canning's refusal to accept the superior status of Castlereagh who had succeeded Perceval as leader of the house of commons. British foreign policy now passed for a decade under unified control. Castlereagh's first task was to hold together the shaky and distrustful elements in the general European opposition to Napoleon; but as the end of the war drew near he worked increasingly to obtain preliminary concert among the allies for the resettlement of Europe. For this purpose he went to the continent at the end of 1813 as British plenipotentiary. In talks at Châtillon he secured acceptance in principle of his plans for a peace settlement under the control of the great powers, and the treaty of Chaumont (March 1814), though in form a military alliance, contained provision for allied co-operation for 20 years after the war. On the fall of Napoleon the treaty of Paris (May 1814) secured immediate British requirements (the restoration of the Bourbon monarchy and the separation of the Low Countries as an independent kingdom), and set Castlereagh free to play a commanding and mediatory role at the peace conference at Vienna (see VIENNA, CONGRESS OF). His main European objectives were to obtain safeguards against Russia (the chief military threat, after France, to European stability) and to strengthen the weak central European areas of Germany and Italy. He and Metternich, the Austrian minister for foreign affairs, dominated the inner negotiations for the definitive treaty of Vienna, though it was Castlereagh who took the lead in resisting the inordinate territorial demands of Russia and Prussia. The final settlement, with some compromises, notably on Poland, was a practical embodiment of his principle of the "just equilibrium."

The other issue to which Castlereagh attached fundamental importance was the regular consultation by the great powers as a body on matters of common concern; and the peace treaty contained specific provision for periodic meetings of the contracting parties. Though the practice of holding such meetings became known as the "congress system," Castlereagh's aim was to make possible diplomacy by conference rather than to establish any system of international regulation by the great powers. The distinction became increasingly apparent in the remaining seven years of his career. The congress of Aix-la-Chapelle (see AIX-LA-CHAPPELLE, CONGRESSES OF) in 1818 readmitted France to the concert of powers. Castlereagh firmly resisted, however, a Russian attempt to institute a league of European powers to guarantee the existing order under sanction of military force. When the liberal movement in Germany after 1818 and the revolutions in Spain and in the kingdom of the Two Sicilies in 1820 brought Austria and Russia closer together, he refused to treat their meeting at Troppau in Oct. 1820 as a full European congress; and after the congress of Laibach (1821) he openly repudiated the Troppau principle of intervention and coercion. His classic state paper of May 1820 emphasized the difference between the despotic states of eastern Europe and the constitutional structures of Britain and France, and made it clear that the British government could only act on the expediency of any given issue and within the limits of its parliamentary system. With the emergence in 1821 of the questions of Greek independence and the fate of the Spanish colonies, however, British political and commercial interests became directly

affected and Castlereagh decided to attend in person the congress of Verona in Oct. 1822. The instructions he drew up for himself showed plainly that he would not sanction forcible interference in either Greece or Spain, and that Britain would ultimately be prepared to recognize *de facto* governments resulting from successful revolutions. Though the cabinet, which now included Canning, may have had some influence in shaping the emphasis of these state papers, it is clear that Castlereagh was preparing for that detachment of Britain from the reactionary policy of the continental powers which was accomplished after his death.

This development was largely hidden from the British public by the personal nature of Castlereagh's diplomacy and his aloofness from public opinion. His apparent involvement with the eastern autocracies was disliked at home, and his role as spokesman for the government in the violent domestic politics of the postwar era kept him in a position of unpopular prominence. As leader of the house of commons he was identified with the repressive policies of the years 1815-19, which saw the Peterloo "massacre" and the six acts, and with the cabinet's unsuccessful introduction in 1820 of a bill to dissolve George IV's marriage with Queen Caroline. He was savagely attacked by Liberal romantics such as Lord Byron, Thomas Moore and Shelley, and his stock characterization in radical cartoons was "Derry Down Triangle," a reference to a baseless charge of flogging prisoners in the 1798 rebellion revived by Henry Brougham (afterward Baron Brougham and Vaux) in 1817. After the abortive Thistlewood plot in 1820 he always carried pistols in self-defense, and during the trial of Queen Caroline he was obliged to take up his residence in the foreign office for greater safety. Yet in his own aristocratic political world he was always a distinguished and commanding figure. Though he was a curiously bad debater and orator, except when replying to attacks, the house of commons trusted him as they never trusted Canning. From 1812 to 1822 he was a leading figure in the government and would certainly have succeeded Liverpool as prime minister had he survived. He was one of the few ministers who had influence with George IV, and the burden of work and anxiety imposed on him by the royal divorce affair of 1820, in addition to his duties at the foreign office and in the house of commons, probably hastened his final collapse. In 1821 there were premonitory symptoms of abnormal suspiciousness, and by the end of the parliamentary session of 1822 he was showing alarming signs of persecution mania. He was, or thought he was, being blackmailed on charges of homosexual acts, and on Aug. 12, 1822, he committed suicide shortly before he was due to set out for Verona.

Character and Achievements.—Castlereagh was a tall and dignified man, inheriting much of the beauty of his mother, with perhaps a hidden strain of the instability attributed to the Hertford family. His physical and moral courage, his patience and outward imperturbability covered a sensitivity of temperament shown in his love of flowers and natural scenery; while his stately appearance and exquisite courtesy made him the idol of women. With an aristocratic disdain for popular approval, an indifference to nationalist passions, and a scorn of abstract theories, he had a serene and unimpassioned intelligence and a civilized conception of the value of freedom, peace and order in international life. His character and achievements were violently misrepresented in his own day; and after his death his work was long overshadowed by the flamboyance of Canning, who gave greater emphasis and publicity to the policy which Castlereagh had been developing in the final phase of his career. The task of reconciling the divergent aims of the allies led him in later years into some ambiguities, and his cardinal aim of maintaining understanding among the great powers was subjected to increasing strain. Yet he remains one of the greatest and most creative of British foreign secretaries. The restraint and realism of the peace settlement after the Napoleonic Wars was more his achievement than that of any other man; and as long as he was in office the idea of the concert of Europe, which was his original contribution to international diplomacy, never broke down.

LONDONDERRY, a county of Northern Ireland, comprises the land between Lough Neagh and the river Bann and the Foyle basin, with small areas east of the Bann near Coleraine and west of the Foyle at Londonderry city. The Atlantic ocean and the county of Tyrone, respectively, mark the northern and southern limits of the county. The area is 804 sq.mi. and the population (1961), exclusive of Londonderry county borough, 111,565.

Roughly triangular in shape, Londonderry has as its main physical girder the Sperrin mountains formed by ancient mica schists and rising to more than 2,000 ft. To the north the glacially scarred Sperrins which sweep across the southern boundary give way to extensive plateaus of basaltic lava, covered with peat bog, which overlie chalk and igneous formations. The lava escarpments are flanked by drift-covered hills and river valleys with wide deltaic terraces. To the south and east Old Red Sandstone and Lower Carboniferous Sandstone cap older rocks and meet igneous rock and intrusive granite of north Tyrone at Slieve Gallion (1,735 ft.). West of the northern limits of the basalt and narrowing the outlet of the Foyle is the long sandy spit of Magilligan point, a raised shingle beach which in 1827 provided the base line for the primary triangulation of the British Isles.

The climate, tempered by prevailing southwesterly winds, is equable and mild; rainfall is plentiful (40-50 in. a year); snow falls on the average on 15 to 20 days, and ground frost occurs frequently during winter and early spring.

About four-fifths of the county is cultivated land and mountain grazing, and there are 14,000 ac. of woodland, reafforestation having vested the hills with a mantle of conifers.

The earliest inhabitants were probably fishermen and hunters from across the North channel but there are few visible legacies of their existence. Archaeologists have, however, uncovered a Mesolithic site (c. 6000 B.C.) at Toome bay on Lough Neagh. Neolithic culture is represented by the massive burial chambers scattered over the county—the giants' graves of folklore; the later raths (circular earthworks) of the early Celt are also numerous. Marauding Vikings of the 9th to 11th centuries frequented the Foyle and the Bann but left few marks of their sojourns; neither did the Normans, who crossed the Bann in the 12th century, make a lasting impression.

The shiring of Ulster was carried out in 1585 and the county, then smaller than at present, was described as the county of Coleraine. Following the defeat of the Irish earls and the confiscation of their land, a plan for the exploitation of the escheated land was promulgated in 1609. Colonization of the land between the Foyle and the Bann was undertaken by the livery companies of the City of London and the Honourable The Irish society (founded in 1610). A charter of 1613 established the county of Londonderry comprising the old county, O'Neill lands of Loughinshollin and small portions of Donegal and Antrim. New towns for the territory were established and these, populated with Scots and English "planters," were developed in much the same way as in the tidewater colonies of the new world. The original buildings of the settlement towns were largely destroyed during the 1641 rebellions and in the wars of the late 17th century. The early 18th century saw the mass migration of dissenting Presbyterians from the county to New England where Ulster frontiersmen contributed in full measure to the advance of the frontier settlement and subsequently the creation of the United States. During World War II Lough Foyle assumed strategic importance as a naval base.

In 1961 the population of the county, including the county borough, was 165,309; that of the county borough and assize town of Londonderry was 53,744. Coleraine (11,912) is the only municipal borough and there are two urban districts, Limavady (4,324) and Portstewart (3,950), and four rural districts. The county comprises one United Kingdom parliamentary constituency (Lon-

BRITISH TRAVEL AND HOLIDAYS ASSOCIATION

QUAYSIDE AT PORTSTEWART

donderry) and part of another (Mid-Ulster); five members are returned to the Northern Ireland parliament.

An expansion of linen manufacturing in the 19th century followed by the introduction of shirtmaking, shipbuilding and spirit distillation marked the first impact on the county of organized industry. Factories are largely centred round Londonderry and Coleraine (chiefly shirtmaking, the processing of milk products and the manufacture of fertilizers, neoprene rubber and acrylic fibre). Linen manufacturing and shirtmaking are the industries of the small towns, and the rural areas are devoted to agriculture. Farms are generally small (25–30 ac.) and independently owned. The principal crops are oats, potatoes and grass seed; stock rearing predominates on the larger lowland farms. There are salmon and eel fisheries in the Foyle and Bann. Portstewart and Castlerock are tourist centres. The county has an excellent road system and is linked by two railway lines with Belfast. There is regular sea traffic between Coleraine and Scottish and northern ports.

LONDONDERRY, a city, parliamentary and county borough, the second city of Northern Ireland, situated on the Foyle, a broad estuary into which flow the rivers Finn, Mourne, Strule, Derg and Deele. The city is 75 mi. W.N.W. of Belfast by road. Pop. (1961) 53,744.

Derry, the older name of Londonderry, comes from the Gaelic word *doire* meaning "oak grove." At that site St. Columba established a monastery in the middle of the 6th century. The fortunes of Derry as an ecclesiastical and monastic centre were varied. It was plundered by Norsemen and is said to have been burned down at least seven times before the year 1200. As a strategic site, Derry was of interest to Anglo-Norman adventurers, being sacked by John de Courci and finally granted by Richard II to Richard de Burgh, well-known as the Red Earl. It served as a strategic point in the Tudor wars against the native Irish, and was destroyed in 1568 by the blowing up of a munition dump. Sir Henry Docwra established a fort at Derry in 1600 as part of a successful plan to enclose Hugh O'Neill, earl of Tyrone. The little town at Docwra's fort was burned down by Sir Cahir O'Dogherty of Inishowen in his short-lived insurrection in 1608. Londonderry received its first charter in 1604, and was granted in 1613 to the City of London as part of the area to be colonized by the City. The town then received the name of Londonderry and was given a municipal corporation. The representatives of the Londoners planned a new town and built the present city walls. The governing charter granted by Charles II in 1662 confirmed an earlier charter of 1614. The district suffered much in the rising of 1641 and subsequent fighting, the city being besieged in 1649. It again experienced siege in 1688–89 when it held out for 105 days against the

forces of James II, being defended with great heroism largely inspired by the Rev. George Walker, rector of Donaghmore, and relieved just before further resistance became impossible. In World Wars I and II it served as a naval base and still functions as such.

The city stands on a hill. It is surrounded by the city walls, about one mile in circumference, having seven gates and several bastions, but modern buildings extend beyond the walls and across the Foyle which is spanned by Craigavon bridge. St. Columba's Protestant cathedral, completed in 1633 and enlarged in 1886–87 contains many relics of the siege. Other important buildings are the Gothic St. Eugene's Roman Catholic cathedral (1873), the guildhall (rebuilt 1908), Magee University college (1865) and Foyle college, a school for boys, founded in 1617.

The staple industry of Londonderry is the manufacture of shirts and collars, and there are many smaller industries including the making of furniture, small ships, sound recorders, tire fabrics and various foods. The city returns one member to the parliament of Northern Ireland and is merged in the Londonderry county constituency for the purpose of returning one member to the United Kingdom parliament. (Hu. S.)

LONDON UNIVERSITY. Plans for a university in London, Eng., were put forward as early as the 16th and 17th centuries, but it was not until after 1825 that a start was made. By then a rapidly growing urban middle class, in which dissent was strongly represented, was making demands for higher education that the older universities, which confined their degrees to members of the Church of England and paid little attention to physics, chemistry and other new branches of learning, could no longer meet in full. At the same time, the state of English medical teaching was arousing public concern.

In 1825 a group of influential dissenters, Whigs and Radicals led by Thomas Campbell, the poet, and Henry Brougham set to work to raise funds for founding a college in London on Scottish and German models to give a broad and wholly nonsectarian education in arts, science and medicine. This college was opened in 1828 as "the London university" in fine classical buildings in Gower street designed by William Wilkins. Church and Tory interests at once responded by founding in 1829 on Church of England principles a rival institution, King's college, which was opened in 1831 in a building adjacent to Somerset house, Strand, designed by Sir Robert Smirke. King's college did not seek university status; but the promoters of "the London university" petitioned the crown for powers to grant both general and medical degrees. This claim aroused widespread opposition, and a compromise was adopted. On Nov. 27, 1836, King William IV granted a charter which established the University of London in the form of a chancellor, and a senate of 36 fellows appointed for life by the crown, to hold examinations and grant degrees in arts, laws and medicine, but without teaching functions. On the same day the Gower street college accepted a charter of incorporation as "London University college." Candidates for examinations were to present certificates of attendance at University college or King's college, but other educational institutions, not necessarily situated in London, could be admitted by the government in connection with the university. But, with no organic link to unite them, the university and the London colleges soon drifted apart, the university developing its examination system primarily for national purposes through a free use of the power to admit provincial and even colonial colleges, while University college and King's college struggled to reach high academic standards unaided by the prestige of full university rank. In 1858 the senate acknowledged the realities of the position by throwing all examinations, except those for medical degrees, open to all candidates irrespective of their place of education. The university thus became, and remained until the end of the century, a general examining body. As such, it was the first body in England to institute degrees in science (1859) and the first to open its degrees to women (1878). Toward the end of the century a strong agitation developed in favour of a teaching university and two royal commissions reported on the question in 1889 and 1894. The existing system had staunch supporters, who feared the results of placing

it under the control of an academic body dominated by local college interests, and a long and at times bitter controversy was ended only in 1898, when the first University of London act became law.

The statutes made under this act, which came into force in 1900, reconstituted the university as a dual-purpose institution. Its governing body, the senate, was composed on its "internal" side of representatives elected by the teachers of certain established London colleges and other educational institutions, grouped in faculties of theology, music, arts, laws, medicine, science, engineering and economics; and on its "external" side of a like number of representatives of the convocation of graduates; a third group of representatives was appointed by the crown in council, the London county council and some other public bodies. The principal colleges received the academic status of "schools of the university" but only University college and King's college had statutory representation in the senate. They and the other schools admitted in 1900 carried on the bulk of the teaching work, and remained legally and financially independent of the senate, whose powers of intervention in their affairs were limited to instituting and appointing the holders of professorships and readerships, recognizing the more junior teachers, regulating the courses of instruction for degrees and periodical inspection. A peculiar feature of the constitution was the recognition of individual teachers, under whom students could follow courses of instruction leading to internal degrees, in a number of educational institutions in London not otherwise connected with the university. The former examining system of the university was placed under an

external council controlled by the convocation members of the senate, and statutory precautions were adopted to ensure that the standard and prestige of the external degrees should not suffer.

Progress was at first delayed by mutual distrust between the internal and external parties, and by lack of additional resources for the new responsibilities which public opinion expected the university to undertake. With a view to strengthening it at its centre, University college in 1905 and King's college in 1908 surrendered their legal independence and in 1907 and 1910 respectively became incorporated in the university, but this example was not followed by other schools. The admission of Imperial College of Science and Technology to the University in 1907 led to the appointment in 1909 of yet another royal commission to review the whole position of the reconstituted university. Its drastic recommendations for replacing the loose federation by a closely articulated unitary organization were suspended by the outbreak of World War I. When in 1924 a governmental committee at length reconsidered the royal commission's report, a much more limited plan of reform was adopted. The principal changes effected in 1926 in the revised statutes which came into force in 1929 were first, the creation of a new body, the court, with supreme authority in matters of finance which extended over the independent schools in respect to all public grants or benefactions; and secondly, the closer association of the schools with the central body, mainly through statutory representation on the senate, which remained the supreme governing body of the university in all academic matters. The court, with 15 (now 16) members, was composed of those representatives of the crown and the local authorities who had hitherto sat in the senate, together with 6 members appointed by the senate and 2 *ex officio* members, the vice-chancellor and the chairman of convocation. The representation of other public bodies ceased. The essential features of the reconstitution of 1900—the federal principle and the dual system of internal and external degrees—were preserved. During the first half of the 20th century a great expansion of the teaching university took place. In 1900 there were 18 schools of the university and in 1902–03 it had 2,000 internal students. By 1963 the university comprised 33 schools (of which 17 were nonmedical and 16 medical) and 11 university institutes (see table), with about 1,050 professors and readers; there were also about 1,450 other recognized teachers. In 1962–63 the internal students numbered 28,603, of whom 5,230 were in "institutions having recognized teachers" not organically connected with the university. All schools of the university engaged in undergraduate teaching also promote advanced study and research. A significant feature of the modern growth of the university has been the development, in supplementation of the main teaching work carried on in the schools, of central institutes directly administered through committees or councils responsible to the senate.

The external work of the university continued to expand after 1900. While the university still registered many technical college and private students, it was increasingly concerned on its external side with fostering the growth of university colleges both in the United Kingdom and in the territories of the Commonwealth of Nations, providing them with advisory services and an examination and degree system during the period of their growth toward full and independent university status. The number of students registered for external degree and diploma examinations of the university in the 1960s was about 27,000.

The colleges and other institutions of the university are dispersed over a wide area, two (Royal Holloway college, near Staines, and Wye college, near Canterbury) being indeed outside London altogether. From 1836 to 1936 the university headquarters were housed by the government, from 1871 to 1900 in Burlington gardens, and later in part of the Imperial institute building at South Kensington. After 1910 the provision of a new headquarters on a central site became a major issue of policy. It was not, however, until 1927 that the university was able to acquire, with the aid of a munificent gift of £400,000 from the Rockefeller foundation, a site of 11½ ac. in Bloomsbury close to University college, on which it erected between 1931 and 1937 a monumental senate house and library to the designs of Charles Holden, the cost

*Original colleges of the university as reconstituted in 1900. †i.e., art history. ‡As London Day Training college; became university institute under present name 1932. §Formerly Bibliothek Warburg, Hamburg, Ger.; for study of classical tradition in art, literature, science, etc. ¶Formerly London Mechanic's Institution and Birkbeck institution; mainly for evening and part-time studies. §Federation of *Central Technical college (1900, now City and Guilds engineering college), *Royal College of Science (1900) and Royal School of Mines. §Formerly King's College of Household and Social Science. §Formerly East London college. §Formerly South-Eastern Agricultural college. §Comprising Institutes of Basic Medical Sciences, Cancer Research, Cardiology, Child Health, Dental Surgery, Dermatology, Diseases of the Chest, Laryngology and Otology, Neurology, Obstetrics and Gynecology, Ophthalmology, Orthopedics, Psychiatry (1924, as Maudsley hospital medical school), Urology; and Postgraduate Medical School of London (1934). †On separation from parent college. ‡Formerly London College of Medicine for Women. ‡‡This group also included from 1900 to 1958 the London College of Divinity (formerly St. John's hall). ††Formerly Hackney and New college. ‡‡Formerly Wesleyan college.

being met by gifts of more than £1,300,000 from local authorities, City companies, business firms, banks and private donors. The Institutes of Education and Historical Research and the school of Slavonic and east European studies are in the same building. Space also has been found on the site for the school of oriental studies, Birkbeck college, the university students' union and the Warburg institute and Courtauld galleries.

In 1949-51 the university acquired, with the aid of the treasury and the London county council, a further 13½ ac. adjoining the original site. It was thus able to realize its long-cherished hope of establishing a "university precinct" in or near which a substantial proportion of its activities could find a focus. In 1959 a comprehensive outline plan for the future development of the whole precinct, prepared by Sir Leslie Martin, was approved in principle.

LONG, CRAWFORD WILLIAMSON (1815-1878), U.S. physician, who first used ether as an anesthetic in surgery, was born in Danielsville, Ga., on Nov. 1, 1815. He received an A.M. degree from Franklin college, Athens, Ga., in 1835 and then read medicine under George R. Grant at Jefferson, Ga. He matriculated at the medical department of Transylvania university, Lexington, Ky., and later transferred to the University of Pennsylvania, Philadelphia. After his graduation in 1839, he went to New York city to walk the hospitals, then returned to Jefferson, where he soon acquired an extensive practice.

Long's imagination was stirred by the observation that injuries were sustained without pain during "ether frolics." On March 30, 1842, Long painlessly removed a tumour from the neck of James Venable, to whom he administered ether. At first, credit was denied to Long, who, as a rural physician, had no opportunities to test his discovery during major operations and cautiously accumulated data to justify publication in 1849 in the *Southern Medical and Surgical Journal*. In the famous ether controversy Charles T. Jackson, Horace Wells and William T. G. Morton (*q.v.*) each claimed the discovery for himself and applied for a national reward from congress. Long claimed no money; he wanted only recognition of the fact that he discovered and used the anesthetic effect of ether in surgery for the first time. Wells, a Hartford, Conn., dentist, conceived the idea, independently of Long, of anesthesia during "laughing gas parties"; he introduced anesthesia for tooth extractions, using nitrous oxide gas, in 1844. Morton, Wells's friend and onetime partner, in 1846 gave the first public demonstration of ether anesthesia in surgery; but he borrowed the idea from Jackson, a chemist and geologist, whose own claim to priority rests on accidental self-observations without witnesses. Long emerges from all the evidence as the discoverer of ether anesthesia in surgery and as a figure justly aloof from the ethically questionable implications of this chapter of medical history. He died at Athens on June 16, 1878.

LONG, HUEY PIERCE (1893-1935), demagogic and flamboyant governor of Louisiana and U.S. senator, was born Aug. 30, 1893, near Winnfield, in an impoverished part of Louisiana, the son

of a farmer. After public school education and brief legal training at Tulane University in New Orleans, he became a lawyer in 1911. Politically ambitious, he was elected to the Louisiana Railroad commission at the age of 25. In 1928, after an earlier unsuccessful candidacy, he won election as governor of Louisiana because of heavy support from rural districts. His picturesque speech and unconventional ways soon made him nationally famous, and he was widely known as "Kingfish." His real importance lay in his ambitious and successful program of public works and public welfare in a state that had been politically static for two generations, and in his concentration of political power into an executive dictatorship unprecedented in U.S. history. In 1930 he was elected to the U.S. senate and then sought to gain national power with a Share-the-Wealth program ("every man a king"), which was tempting to a depression-shocked public. By 1935, in open opposition to Pres. F. D. Roosevelt and in absolute control of Louisiana, he was at the height of his power when Carl Austin Weiss, the son of a man whom he had vilified, assassinated him in the capitol building at Baton Rouge.

Long apparently felt genuine sympathy for the underprivileged, and his regime brought tangible material progress and welfare to rural Louisiana. His vindictive and domineering temperament, however, led him to destroy the process of self-government in Louisiana, and his folksy, democratic manner diverted attention from the reality that he was ruthlessly autocratic in his rule.

His brother, Earl K. Long (1895-1960), served as governor of the state, 1939-40, 1948-52, and 1956-60. Huey Long's son, Russell B. (1918-), was elected U.S. senator from Louisiana in 1948 and re-elected in 1950, 1956 and 1962.

See Allen P. Sindler, *Huey Long's Louisiana* (1956) and Stan Opatowsky, *The Longs of Louisiana* (1960). (D. Pa.)

LONG BEACH, a city of Los Angeles county, Calif., U.S. 20 mi. S. of Los Angeles, on San Pedro bay, is a tourist resort and an important industrial and commercial centre. Catalina Island is 23 mi. off the coast and the Palos Verdes hills lie to the west. The elevation ranges from 14.5 ft. below sea level to 170 ft. above sea level. Long Beach completely surrounds the cities of Signal Hill and Lakewood, and the three cities, along with Catalina, form a unified school district. The site was once a portion of a Spanish land grant given to Manuel Nieto in 1784 which was divided among his five children as ranchos. Two of the latter, Los Alamitos and Los Cerritos, which included most of modern Long Beach, passed into the hands of Abel Stearns and John Temple in the early 1840s. By 1882 both ranchos had been purchased by the Bixby family. William E. Willmore made the first attempt to found a town in 1882; after securing an option from Jotham Bixby on 4,000 ac., he organized the American colony, but the plan collapsed in 1884. The Long Beach Land and Water company continued with the project and gave the seven miles of wide strand the name Long Beach. It was first incorporated in 1897.

Until 1921 Long Beach was a seaside resort with a largely transient population. Harbour development was made possible by the acts of 1911 and 1925 by which the state granted to the city the bordering tidelands and submerged lands. Bond issues and revenue from oil and gas provided funds to develop an excellent man-made harbour. The discovery of oil in 1921 at Signal Hill resulted in increased industrial activity and a spectacular leap in population. After 1947 the city was plagued with litigation and legislation over the revenue accruing from the tideland reserves where the removal of oil and gas also produced the serious problem of subsidence.

In March 1933, Long Beach suffered a destructive earthquake after which a widespread building program was inaugurated. During World War II a naval base (now a shipyard) was established there. Douglas Aircraft corporation built and progressively expanded a plant, which at peak production employed 30,000 workers. In nearby Seal Beach and Los Alamitos, a naval ammunition and net depot and air station were opened and continue to operate. A naval hospital was also erected, which became a veterans administration hospital. A modified council-manager form of government, with some aspects of the commission type, was adopted in 1921. Gas and water utilities are municipally owned.

The port of Long Beach has modern facilities, used by about 1,700 ships annually, and can berth 30 vessels at one time. After World War II most of the commerce was with Japan, and the principal export was petroleum. Long Beach and Los Angeles harbours are connected by Cerritos channel. Fisheries are important, and thousands of tons of fish are processed in local canneries. Freeways serve the port and the city. Diversified industries include automobile assembling and the manufacture of oil-drilling equipment, aircraft, soap and toiletries, chemicals, paints, furniture, clothing, furnaces and heaters, ceramics and glass, paper, plastics, and building and insulation products.

The great inundation of population after World War II produced grave educational problems, and it became necessary to double the capacity of the public schools. Long Beach City college (established 1927) is one of the largest two-year colleges in the nation; Long Beach State college (1949) has an enrollment of about 10,000. The city supports an art centre, an extensive library system, a symphony orchestra, a municipal band, a light opera association and community playhouses. It also maintains parks, municipal golf courses, a stadium, a marine stadium and a modern marina (1,250 ac.) for private ocean-going craft. Pop. (1960) 344,168; for the Los Angeles—Long Beach standard metropolitan statistical area see LOS ANGELES. For comparative population figures see table in CALIFORNIA: Population. (H. P. Jo.)

LONG BEACH, a resort and residential city in Nassau county on Long Island, N.Y., U.S. Henry Hudson's log from the "Half Moon" reported in 1609 a "long glistening bar of exceptionally white sand" off the westerly, southern shore of the island. More than 200 years later the name Long Beach was given to this 7-mi. sand bar approximately 6 mi. from the New York city line. The white sandy beach, one of the few on the east coast which faces directly south off the Atlantic ocean, was ideally situated for New York vacationists. In 1880 the Long Beach hotel was constructed. In the early 20th century the city was developed into a thriving resort where many prominent citizens maintained summer residences. However, after the 1930s Long Beach attracted an increasing number of permanent residents, so that its character as a community became more suburban. For comparative population figures see table in NEW YORK: Population. (W. M. D.)

Longbenton, an urban district in the Wallsend parliamentary division of Northumberland, Eng., adjoining the north-eastern boundary of Newcastle upon Tyne for which it is a residential area. Pop. (1961) 44,633. The church of St. Bartholomew, originally built in the 12th century, stands between Longbenton and Killingworth. Thomas Addison, the physician, was born at Longbenton in 1793 and George Stephenson (q.v.), the inventor of the locomotive, was at one time the engineer at Killingworth colliery and his house is still preserved. In the 17th century the Newcastle races were run on Killingworth moor, later known as the district of Forest Hall and West Moor. The knights hospitallers also held land in Killingworth that was granted to them after 1308. Weetslade urban district was merged with Longbenton in 1935 to form the present district. Other than agriculture, the principal industry for about 200 years has been coal mining.

LONG BRANCH, a city of Monmouth county, N.J., U.S., is located on the Atlantic coast, 45 mi. S. of New York. For years it was known as one of the oldest summer resorts, but with the growth of the garment and electrical industries in the 20th century, it gradually became an all-year residential community. Fishing and truck farming are also significant. Its name stems from the fact that it borders on the eastern or long branch of the South Shrewsbury river.

The first village was established at West Long Branch, one mile from the shore. The section nearer the beach developed later, when there was a regular line of stages from Philadelphia and a steamboat service from New York. In 1860 the first railroad arrived. In the late 19th and early 20th centuries visitors to the resort included the presidents U. S. Grant, Rutherford B. Hayes, Benjamin Harrison and Woodrow Wilson. Pres. James A. Garfield, after he was shot in Washington, D.C., was brought to his summer cottage at Elberon, where he died in 1881. Long Branch

was chartered in 1904 and includes the communities of Elberon, North Long Branch and West End. For comparative population figures see table in NEW JERSEY: Population. (H. F. Wt.)

LONGCHAMP, WILLIAM (d. 1197), chancellor and justiciar to Richard I of England, was of Norman origin. He received a legal training and his first known employment was as official for the archdeaconry of Rouen. Later he became chancellor to Richard, then count of Poitou, and when Richard became king (1189) Longchamp continued as his chancellor. Consecrated as bishop of Ely (Dec. 31, 1189), he was, after Richard's departure on crusade, appointed joint justiciar (March 1190) with Hugh du Puiset, bishop of Durham. He was appointed papal legate by Clement III in June 1190, in which month he also became sole justiciar, although a council was nominated by the king to assist him. His rule was unpopular and many therefore supported the king's brother John when he returned to England early in 1191, obviously scheming to obtain not only the succession but possibly the crown. A series of disputes ensued over the custody of various castles, and Longchamp's position was weakened when his legateship lapsed on the death of Pope Clement in March 1191. Meanwhile Richard sent Walter of Coutances, archbishop of Rouen, to intervene (June 1191), with a commission fully empowering him to make changes in the administration. A settlement was reached in July between John and Longchamp, but in September Henry II's illegitimate son Geoffrey, now consecrated as archbishop of York, returned to England, like John violating an oath he had taken to stay away. Longchamp tried to prevent his landing and had him removed from a church at Dover in which he had taken refuge. This incident aroused the indignation of the clergy. Longchamp now had few friends, and in October he was superseded as justiciar by Walter of Coutances and retired to France. He visited Richard I in captivity early in 1193. Richard was convinced of his loyalty and retained him in the office of chancellor until his death at Poitiers on Jan. 31, 1197.

LONG EATON, an urban district (1895) of Derbyshire, Eng., lies 10 mi. E.S.E. of Derby and 7½ mi. S.W. of Nottingham by road on the Erewash canal. Pop. (1961) 30,476. The church of St. Laurence, with a Norman aisle, stands in the market place where open markets are held twice weekly. Trent college, a boys' boarding school, was founded in 1866. West park, between the college and the Erewash canal, provides facilities for sport. Formerly an important centre of the lace trade, the town's manufactures include light textiles, pressed stainless steel domestic products, furniture, upholstery, hosiery, elastic and elastic braiding. Adjoining the urban district are the large railway marshaling yards at Toton. (R. Br.)

LONGFELLOW, HENRY WADSWORTH (1807–1882), the most popular of U.S. poets in the 19th century, was born in Portland, Me., on Feb. 27, 1807. On both sides of the family he came from Yorkshire stock. His mother, Zilpah Wadsworth, was the daughter of a general in the American Revolution, who traced his ancestry back to the Plymouth Pilgrims. His paternal ancestor, a blacksmith, settled in Byfield, Mass., in 1680. His early education was in private schools and in the Portland academy. He entered Bowdoin college as a sophomore and graduated in the class of 1825 with Nathaniel Hawthorne. At college he studied unremittingly to fit himself for a literary career. He was attracted especially to Sir Walter Scott's romances and Washington Irving's *The Sketch Book*. While an undergraduate he published verses in national magazines. His father wanted him to enter his law office, but the future poet wrote, "I most eagerly aspire after future eminence in literature." During his junior year he had so deeply impressed a college trustee by the fluency with which he translated an ode of Horace that on graduation he was offered a professorship in modern languages provided that he would first study in Europe.

On the continent he learned French, Spanish and Italian, but refused to settle down to a regimen of scholarship at any univer-

sity. In 1829 he returned to the U.S. to be a professor and librarian at Bowdoin. There he proved himself an excellent teacher. He wrote and edited textbooks, translated poetry and prose, and wrote essays on French, Spanish and Italian literature.

He felt himself somewhat too isolated at Bowdoin, so when he was offered a professorship at Harvard, with the hint of another opportunity to go abroad, he gladly accepted and set forth for Germany in 1835. Before settling down he visited England, Sweden and the Low Countries. Saddened by the death of his wife in 1835 he ceased his wandering and settled at Heidelberg where he fell under the influence of German romanticism. The transcendental quality of such poetry as in Novalis' "Hymns to the Night" induced in him an introspective mood.

In Oct. 1836 he sailed for home and returned to Harvard. Meanwhile he had published a book of travel sketches, *Outre-Mer*, vignettes of life in France, Spain and Italy, written under the influence of Irving's *Sketch Book*. He lacked Irving's sense of humour and capacity for creating character and the book did not succeed. In 1839 he published *Voices of the Night*, a volume containing "The Psalm of Life" and "The Light of the Stars"—poems that became immediately popular. Early in the same year he brought out *Hyperion*, a romantic novel idealizing his European travels.

For 18 years he presided successfully over Harvard's modern language program, but his "poetic dreams were shaded by French irregular verbs," and he longed for freedom. The poet in him was kept alive by his work as a translator. In 1841 his *Ballads and Other Poems*, containing "The Wreck of the Hesperus," came out and swept the nation. In 1854 he left teaching and entered upon his long-cherished dream of building "some tower of song with lofty parapet." While this major ambition was maturing he wrote a few *Poems on Slavery* (1842), finished productions which lacked, however, the power of John Greenleaf Whittier's Hebraic denunciations. He was more at home in *Evangeline*, an idyll of Acadia skilfully written in dactylic hexameters, which reached almost every literate home in the U.S.

The Song of Hiawatha, published in 1855, proved another popular success. With Henry Rowe Schoolcraft's two books on the Indian tribes of North America as the base, and the trochaic metrics of the Finnish epic *Kalevala* as his medium, he fashioned one of his most artistic productions. Its appeal was immediate. In 1858 he wrote *The Courtship of Miles Standish* in the "Evangeline" measure. The material is less idyllic than that of the earlier story, but the metrics are enriched by a more varied accent.

The death in 1861 of his second wife, who died of burns after she had accidentally set her dress on fire while sealing packages, deepened his melancholy (cf. "Cross of Snow," 1879). Her death drove him for spiritual relief into translating that "Medieval Miracle of Song," the *Divine Comedy of Dante Alighieri*, one of the most notable translations of the Florentine to that time. While engaged in this work he wrote six sonnets on Dante which are among his finest productions.

The Tales of a Wayside Inn, modeled roughly on the plan of Geoffrey Chaucer's *Canterbury Tales* and published in 1863, reveals his marked narrative gift. The first poem, "Paul Revere's Ride," became a national favourite. He published in 1872 what was intended to be his masterpiece, the *Christus: a Mystery*, a trilogy dealing with the subject of Christianity from its beginning, and followed this trilogy with two fragmentary dramatic poems: "Judas Maccabaeus" and "Michael Angelo." But his genius was not dramatic, as he had demonstrated earlier in *The Spanish Student* (1843), although it should be noted that these neglected later works contain some of his most effective writing.

In the 19th century Longfellow was loved and honoured at home and abroad. Oxford conferred upon him a D.C.L. and Cambridge an LL.D. in 1868. After his death March 24, 1882, a memorial to him was unveiled in Westminster abbey. Some years after his death a violent reaction against his poetry set in. Critics who had put the romantic movement behind them and who deplored his sometimes heavy-handed didacticism appeared to take pleasure in reducing him to the status of a hearthside rhymers. This harsh dismissal was somewhat unfair. His poetry is still loved by the

unpretentious, and such poems as "My Lost Youth" transcend the metrical scaffolding on which they are erected. His poetry rarely touches greatness; he does not produce the "martial music" of John Milton or Homer, but good singing poetry can be found throughout his work.

BIBLIOGRAPHY.—See the Riverside edition of Longfellow's *Works* (1886). Still of importance although outdated is the biography of the poet by his brother Samuel Longfellow, *Life of Henry Wadsworth Longfellow With Extracts From His Journals and Correspondence* (1886), supplemented by his *Final Memorials of Henry Wadsworth Longfellow* (1887). E. C. Wagenknecht's *Longfellow: a Full-Length Portrait* (1955) incorporates much new material hitherto scattered or unpublished. The most thorough account of the formative years is L. R. Thompson's *Young Longfellow (1807-1843)* (1938). H. S. Gorman's *A Victorian American, Henry Wadsworth Longfellow* (1926) has interest as an adversely critical biography. See also Mrs. Longfellow, *Selected Letters and Journals*, ed. by E. C. Wagenknecht (1956).

No comprehensive bibliography of Longfellow exists. Of limited value is L. S. Livingston's *Bibliography of the First Editions in Book Form of the Writings of Henry Wadsworth Longfellow* (1908).

Among special studies may be noted: Iris L. Whitman, *Longfellow and Spain* (1927); J. T. Hatfield, *New Light on Longfellow; With Special Reference to His Relations to Germany* (1933); A. R. Hilen, *Longfellow and Scandinavia* (1947); and C. L. Johnson, *Professor Longfellow of Harvard* (1944). P. Morin's *Les Sources de l'Oeuvre de Henry Wadsworth Longfellow* (1913) is useful but must be supplemented with many subsequent articles. The Introduction to Odell Shepard's edition of *Representative Selections* in the "American Writers Series" (1934) is valuable, and William Dean Howell's description of his friend in *Literary Friends and Acquaintance* (1900) is of historical interest. Examples of early 20th-century opinion may be found in Paul Elmer More's *Shelburne Essays*, vol. v (1908) and Bliss Perry's *Park-Street Papers* (1908). (Wt. S.; X.)

LONGFORD (LONGPHORT), a county of the Republic of Ireland in the extreme northwest of the Leinster province, bordering Cavan in Ulster to the northeast, and two Connaught counties, Leitrim and Roscommon, to the west. Longford does not possess the rich large farms characteristic of the best areas of Leinster but rather shares the small farms so characteristic of Connaught and Ulster. It covers 403 sq.mi. Pop. (1961) 30,642.

On the west the boundary is the Shannon, with part of Lough Ree inside the county. At the northern end of this lake there is a crossing place, Lanesborough, with another at Termonbarry, 7 mi. farther north. From the Shannon, just south of Roosky, the boundary with Leitrim and Cavan runs through farmed lowlands to Lough Gowna, an intricate lake with many ramifications, in the Erne valley. The eastern boundary crosses a water parting to the Inny river, a Shannon tributary, leaves it after a few miles to wander across the lowland, joins it again and finally sweeps across to Lough Ree. Effectively therefore the county is merely a part of lowland Ireland of no great size, but even so, this lowland has considerable structural variety. The general surface, floored by Carboniferous Limestone, rises from the Shannon to an altitude of 200-400 ft., but there are exposures of pre-Carboniferous rocks in the isolated hill at Ardagh (659 ft.) and in the hills to the west of Lough Gowna, which rise to 916 ft. in Corn hill. Much of the country between the heart of the Irish central lowland and the north is of this type, mainly a lowland varied by several ridges of higher land, but it is thickly plastered with glacial drifts, which in the north of County Longford grade into drumlins: few areas of solid rock are exposed. The disorganization of drainage by the glaciation has produced large areas of fens on which bogs have grown. One-fifth of County Longford is rough pasture, chiefly peat bog, but also including some meadows, known as callows, by the Shannon, which are flooded in wet seasons but valuable in drier periods.

The early name of Longford was Annaly or Analé, a principality of the O'Farrells. Then in Meath, it was granted by Henry II to Hugh de Lacy, who started an English colony. On the division of Meath into two counties in 1543, Annaly was included in Westmeath, but in 1569 it was made shire ground under the name of Longford.

Oliver Goldsmith lived during childhood at Pallas, near Ballymahon in the county, and the family of Maria Edgeworth, the novelist, lived at the demesne town of Edgeworthstown, sometimes known as Mostrim.

The county is administered by a county council, which meets at Longford, and shares a county manager with Westmeath. It is also united with Westmeath for electoral purposes, and the two counties return five members to *dáil Éireann*. Granard and Longford are urban districts.

In County Longford hardly one-tenth of the farmland is given to crops, chiefly oats and potatoes. Most farms are of less than 30 ac. and their main concern is to pasture cattle, chiefly for export eastward to the richer and larger farms of County Meath. Some dairying is carried on, especially in the north. Only one-quarter of the county's population live in towns, of which the largest is Longford (3,558 in 1961), which has the Roman Catholic cathedral of the Ardagh diocese (with Clonmacnoise). The other towns include Granard (1,086), Ballymahon (835) and Edgeworthstown (635).

See James P. Farrell, *History of the County of Longford* (1891). (T. W. Fr.; Hu. S.)

LONGFORD (LONGPHORT), the county town of County Longford, Republic of Ireland, is on the Camlin river, 76 mi. W.N.W. of Dublin. Pop. (1961) 3,558. The principal building is the 19th-century St. Mel's Roman Catholic cathedral for the diocese of Ardagh and Clonmacnoise, which includes nearly all of Longford, most of Leitrim and parts of Offaly, Westmeath, Roscommon, Sligo and Cavan. Longford, anciently a fortress of the O'Farrells whose stronghold no longer exists, has a castle dating from the 17th century. It is also associated with the Clinton family, including Adm. George Clinton (c. 1686–1761), governor of Newfoundland and later of New York. Trade is in grain, butter and bacon. There are corn mills, a spool factory and tanneries.

The ancient name of the town was Athfada, and there a monastery is said to have been founded by St. Idus, a disciple of St. Patrick.

LONGHI, ALESSANDRO (1733–1813), Italian painter, etcher and biographer of Venetian artists, the most important Venetian portrait painter of his day, son of Pietro Longhi (q.v.), was born and died at Venice. His father gave him his first training but quite soon put him to study under the Rembrandtesque painter of portraits and fancy subjects, Giuseppe Nogari. In 1759 he was elected a member of the Venetian academy, for which he painted one of his rare subject pictures, the allegorical "Painting and Merit." In 1762 Longhi issued his book *Compendio delle Vite de' Pittori Veneziani Istorici piu rinomati del presente secolo con sui ritratti dal naturale delineati ed indisi*, one of the most important source books for the history of Venetian 18th-century painting. Both portraits and text were printed from plates he etched. In addition, he etched some of his own and some of his father's works. His work is best seen at Venice. (F. J. B. W.)

LONGHI, PIETRO (PIETRO FALCA) (1702–1785), Italian painter of small scenes of Venetian social and domestic life, was the son of a silversmith in whose workshop he received his first training. Later he worked under the Veronese history painter Antonio Balestra, but his one important work of this sort, the monumental ceiling of the "Fall of the Giants," executed in 1734 for the Palazzo Sagredo, was a complete failure. It is likely that it was because of this that he left Venice for a time and studied at Bologna under Giuseppe Maria Crespi. After his return to Venice he devoted himself to painting somewhat in the manner of Nicolas Lancret but more satirical. He also painted occasional portraits. Longhi was also undoubtedly influenced by Dutch genre painting, of which there was at least one important collection in Venice at that date. His paintings, like those of Antoine Watteau, were based on carefully observed figure drawings, a large number of which survive. Many of his paintings were engraved. He was elected to the Venetian academy at its foundation in 1756 and died in Venice on May 8, 1785. His works are best seen at Venice, though there are a few in London. (F. J. B. W.; X.)

LONGHORN (TEXAS LONGHORN), the breed of cattle that formed the basis of the ranching industry of the American west during the 19th century. Texas longhorns made up the bulk of the great herds that were driven by cowboys from southern Texas to Kansas for shipment east by rail, and later to the northern plains states, to the Pacific coast and even into Canada.

The foundation stock of the Texas longhorns were the Mexican breeds of predominantly Spanish blood brought by the settlers from New Spain, who established missions and colonies in North America. In the territory that is now within the limits of the United States, California and Texas became the chief breeding grounds. In 1690, 200 head of cattle were brought up from far south of the Rio Grande to be released at a mission settlement in eastern Texas near the Louisiana line. By the time a party of 15 families from the Canary Islands reached San Antonio in 1731 mission ranches of the region already had numerous cattle. Yet each family came provided with a yoke of oxen, ten nanny goats and a buck, ten ewes and a ram, five sows and a boar, five mares and a stallion, five cows and a bull. All down the San Antonio river to the Gulf of Mexico stock raising became almost the only civilian occupation.

Anglo-American colonists who began entering Texas in 1821 introduced milk cows and a few bulls derived from English breeds. They found wild, ownerless Spanish cattle of various shades and colours, which they called "mustang" cattle, scattered over vast areas east of the plains. They had become heavier and more rangy than the standard Mexican breeds. Long-legged and long-walking as well as long-horned, they could endure thirst and fight off wolves or even grizzly bears. They were more hardy than meaty. The curves of the horns, often beautiful, were more striking than the space from tip to tip, and the shapes of horns were as various as colours of hair. Many cows wore long horns but the climax of horn growth was on "aged" steers, six years old and up, some with horns spreading as much as six feet. Cattle from Mexico—and during trail-driving days many came north across the Rio Grande—were generally smaller than the Texas longhorns, and seldom were their horns so heavy. Spanish rancheros had ignored selective breeding, and the American colonists found it difficult to control breeding on unfenced ranges. They hunted down and shot many wild cattle for meat. By the time Texas became a republic (1836) herds of cattle were being driven to New Orleans to be sold as beef. In the 1840s and 1850s small herds were driven to Missouri and even as far north as Chicago.

People flocking to California as a result of the discovery of gold consumed, for a time, more meat than the native stock could supply. High prices led to the importation of herds of Texas longhorns. While in time a good many California cattle were driven to Oregon and thence east, it was mainly Texas longhorns that occupied the vast territories left vacant by the wholesale slaughter of buffaloes and the confinement of Indians to reservations.

When the American Civil War ended in 1865 Texas had between 3,000,000 and 4,000,000 cattle, hundreds of thousands of them unbranded and feral because the men to manage them had been away as soldiers for four years. The great drives began in 1867 when Abilene, Kan., the first "cow town" of the west, became a buying, selling and shipping centre on the Union Pacific railroad. The Chisholm trail, which originally terminated at Abilene, was a corridor opening out of a vast breeding ground to vacant, virgin ranges. Herds of big steers were driven north from Texas to mature and stock cattle to breed. The Western trail made Dodge City famous.

For a time the westward expansion of population merely passed over the Great Plains and the fringing deserts and mountains. These spaces were occupied by the ranching industry, projected from the south. Some longhorns were driven as far north as the plains of Alberta, Can., but most came to graze the grasses of the Indian Territory (later Oklahoma), western Kansas, Nebraska, the Dakotas, Wyoming, Montana and Idaho. Tens of thousands were driven into New Mexico and Arizona. Before the trails were plowed under and fenced across, by 1890, 10,000,000 longhorns had been driven out of Texas. With them came the Texas cowboy, the most picturesque representative of the cattle industry (see Cow-boy).

Longhorns were eventually nearly bred out of existence in favour of meatier types. In the late 1920s the U.S. forest service, after looking over many thousands of cattle in lower Texas, selected 27 head of longhorns to place in the Wichita Mountains Wildlife refuge, near Cache, Okla. A few outstanding bulls were acquired

later. A herd of about 300 longhorns is maintained in a fenced pasture of 30,000 ac. Partly because of the very nutritious grasses in the refuge area these longhorns are heavier than their south Texas progenitors, and they are magnificent representatives of the breed. See also CATTLE: Breeds.

LONGINUS, the name assigned to the author of the treatise *On the Sublime*, a Greek work of literary criticism once mistakenly attributed to the Neoplatonist Cassius Longinus.

On the Sublime.—The earliest surviving manuscript of the treatise (*Parisiensis graecus* no. 2036; belonging to the 10th century A.D.) ascribes it to "Dionysius Longinus" in its heading; and the first printed editions (from 1554) followed this ascription. It was long unnoticed that the index to the manuscript read "Dionysius or Longinus," implying a guess that the author might be either Dionysius (*q.v.*) of Halicarnassus or Cassius Longinus. David Ruhnken in the 18th century tried to equate Dionysius Longinus with Cassius; but later studies discredited this equation. Identifications with Plutarch and with Dionysius of Halicarnassus were also shown to be untenable, and scholars mostly agreed that the author was someone otherwise unknown—to be designated by them as Pseudo-Longinus. In 1938, however, G. C. Richards (*Classical Quarterly*, xxxii, 3) tried to ascribe the treatise to Pompeius Geminus, the correspondent of Dionysius. Since the treatise is designed to remedy the faults of a work on the same subject by Caecilius of Calacte and since Manilius (as Richards argues) seems to quote from it, it is thought to have been written early in the 1st century A.D. About one-third is lost.

By sublimity (*Gr. hypsos*) the author means "excellence in language," the "expression of a great spirit," the power to provoke "ecstasy" and to move any reader however often he reads the passage. The work is thus a guide to an effective style. Sublimity is opposed alike to bombast, to silly conceits, to sentimentality and to frigidity. Quotations illustrate the sublime and its opposite throughout the treatise, some of them preserving work that would otherwise be lost (one of Sappho's odes is an example); Homer, Demosthenes and Plato are the author's chief models. The sources of sublimity are: greatness of thought (which may be inborn but can be acquired by trying to emulate great writers of the past); strong handling of the passions; skilful use of figures of thought and of speech; proper choice of language and metaphor; and composition (including musical or metrical effects in prose). Finally the author asks whether the contemporary dearth of sublime writers is due to the disappearance of democracy and answers no, it is due to the obsessive pursuit of wealth and cheap popularity.

Nicolas Boileau-Despréaux (*q.v.*) made the treatise the bible of European classicism. There are editions of the Greek text by A. O. Prickard in the Oxford series (1906; 2nd ed. 1947); and by W. Rhys Roberts, with English translation and appendices (2nd ed. 1909). There is also a separate translation by A. O. Prickard (1906).

Cassius Longinus.—Cassius Longinus (c. 213–273) was a nephew of the rhetorician Phronto of Emesa (Homs in Syria). Having been a pupil of the Neoplatonist Ammonius Saccas at Alexandria, he taught philosophy, philology and rhetoric at Athens; and Porphyry was a pupil of his before going to Rome to join Plotinus. The doctrine of Longinus that ideas exist outside the mind was rejected by Plotinus, and his work *On First Principles* drew from Plotinus the comment that Longinus was "a philologist but no philosopher"; but even so the two had a considerable respect for one another. Having gone to Palmyra to teach Greek literature to Queen Zenobia, Longinus became one of her closest advisers and inspired her anti-Roman policy. When this ended in disaster, Longinus was handed over to the emperor Aurelian, who put him to death.

Fragments survive of Longinus' works. A substantial part of his *Art of Rhetoric* is extant, but his celebrated *Philological Discourses* are lost. He also wrote several works of Homeric studies and composed a number of specialized word lists. Eunapius calls

him "a living library and a walking university."

LONG ISLAND, a fragment of the North American continent extending 118 mi. E.N.E. from the mouth of the Hudson river on the northeastern shore of the United States. It roughly parallels the south shore of Connecticut from which it is separated by Long Island sound (90 mi. long) and lies southeast of the mainland of New York state, of which it is a part.

The island is from 12 to 23 mi. wide and has an area of 1,743 sq.mi. The east end is divided into two narrow peninsulas by three bays, Great Peconic, Little Peconic (in which lies Shelter Island) and Gardiners (in which lies Gardiners Island). The northern peninsula, about 25 mi. long, culminates in Orient point; the southern peninsula, about 40 mi. long, ends in Montauk point, the eastern extremity of the island. The north shore of the island is broken in its western half by Flushing bay, Little Neck bay, Manhasset bay, Cold Spring harbour, Huntington bay, Smithtown bay and Port Jefferson. The south shore has Jamaica bay, with many low islands and is nearly cut off from the ocean by the narrow spit of Rockaway beach; and the ill-defined Great South bay, which is separated from the Atlantic by the narrow Long beach, Jones beach and Oak Island beach and by the long peninsula called Fire Island or Great South beach. Still farther east is Shinnecock bay, about 10 mi. long and cut off from the ocean by a narrow beach.

Physiography, climate and location have combined to make Long Island one of the richest and most important garden spots in the United States. The hills of glacial moraine and much of the outwash plains of the southern half of the island, covered for centuries with forest mold, offer a rich soil to the husbandman. A mild maritime climate brings the spring earlier and holds the autumn later than in the continental interior at the same latitude.

History.—When the Europeans first settled on Long Island, they found the area occupied by Indians who were generally of Delaware stock and who, according to early accounts, were divided into a number of small groups, loosely called tribes. There were supposedly at least 13 of these major groups and there may have been more. As part of the Atlantic coast line claimed by England, the island was part of the territory originally included under the jurisdiction of the Plymouth company in the early 1600s and later in 1635 its title was presumably conveyed to the earl of Stirling (Sir William Alexander) by Charles I. The earl's agent, James Farret, was sent to the area and conveyed land titles to groups of individuals between 1635 and 1640.

Dutch interest in this part of the new world had been aroused by the voyage of Henry Hudson in 1609 and resulted in the Dutch West India company setting up a trading post on Manhattan Island in 1624. Long Island was part of the territory claimed by the company even though it conflicted with English claims to the same area. There is some evidence of settlement in the extreme western part as early as 1625; certainly Dutch settlers crossed the East river in the mid-1630s and located in what is now Kings county Breuckelen (Brooklyn), Amersfort (Flatlands), Midwout (Flatbush) and Nieuw Utrecht (New Utrecht) were Dutch communities established under the authority of the company from 1636 to 1660.

In 1640 Englishmen from Lynn, Mass., under a Stirling patent, attempted to settle near Manhasset bay but were warned away by Gov. William Kieft of New Netherland, who would not admit the validity of the English claim. Later that year these people settled at Southampton, toward the eastern end of the island; at about the same time a group from New Haven located at Southold, a little to the north. These two settlements together with the Gardiner family on Gardiners Island (1639) were the first English groups on the Long Island scene. Another band of English settlers obtained a patent from Governor Kieft in 1644 to found Hempstead under the Charter of Freedoms and Exemptions. Other English towns, Gravesend (1645), Flushing (1645), Newtown (1655) and Jamaica (1656), were set up in similar fashion with the inhabitants swearing allegiance to the Dutch authorities. By the treaty of Hartford of 1650 between New Netherland and the United Colonies of New England, a demarcation line was drawn from Oyster bay to the ocean, recognizing the island as Dutch to the west and English to the east.

In March 1664 Long Island was part of the area given to the duke of York by Charles II and in August the conquest of New Amsterdam and the Dutch territory was effected. By this time the English settlements in the eastern part of the island had associated themselves generally with either New Haven or Connecticut, the latter making some claim to the Long Island area by its charter of 1662. Besides Southampton and Southold, the eastern towns included East Hampton (1648), Shelter Island (1652), Huntington (1653), Oyster Bay (1653), Brookhaven (1655) and Smithtown (1663).

Long Island, together with Westchester and Staten Island, became known as Yorkshire and was governed by the Duke's Laws promulgated at Hempstead in March 1665. In 1683 Yorkshire was abolished and the county system introduced in the province with Long Island receiving three of the original counties—Suffolk, Queens and Kings. The period of the American Revolution saw Long Island a hotbed of activity on the part of both Loyalist and Patriot, and its coastal area was the scene of raids by privateers and organized military units. For the entire period of the British occupation of New York city, Long Island was the major source of supplies of wood and food, and its western area was continuously occupied by detachments of British troops. A major political change occurred in 1898–99, when the three eastern towns of Queens county—Hempstead, North Hempstead and Oyster Bay—formed the new Nassau county and the other towns in Queens became part of New York city.

Industries.—During the 19th century Long Island was chiefly known for its agriculture and its fishing industry. Manufacturing was present in the metropolitan area of Kings county and to a certain extent in some other regions. Long Island agriculture of the 17th and 18th centuries was characterized by the self-sufficient farm. Toward the end of the 18th century some farmers began selling their surplus crops in New York. Connection with this market was made by wagons from the farms at the western end of the island and by small coasting boats from the homesteads of the north shore. Two events in the first half of the 19th century established Long Island agriculture on its modern basis. In 1825 the completion of the Erie canal gave New York city a connection with the continental interior and allowed a swift development which made it the metropolis of North America. In 1844 the Long Island railroad was completed to Greenport. The growth of New York and the completion of the railroad caused the general farms to be turned into market gardens, cultivated intensively.

Whaling was the most important maritime industry. So far as Long Island was concerned, the fishery had its origin in the 17th century at East Hampton and Southampton. Early in the 19th century Sag Harbor became the chief Long Island whaling port. The village, dependent almost solely upon whaling, prospered in the golden age of the industry and suffered heavily when whaling swiftly declined after the middle of the century. Throughout most of the 19th century the menhaden fishery flourished along the southern shore and in Peconic bay. Before the end of the 18th century, the blue point oyster bed in Great South bay had been discovered and was being worked, and in 1855 New York permitted the leasing of sea bottom, which was not part of a natural bed, for the purpose of establishing oyster farms. Oystering under the new conditions became one of the most important industries, not only of Great South bay, but of Peconic bay and some of the north shore harbours. Throughout the history of the island, deep-sea fishing—for cod, mackerel, bluefish, sea bass, weakfish, etc.—has been the major support of many Long Island families. Fishing for recreation has always been of importance and Long Islanders for many decades have provided services for sport fishermen.

In the colonial period milling of various kinds was carried on in the scattered settlements and some types of primitive manufacturing were engaged in to a limited degree. The chief manufacturing enterprises of the first half of the 19th century were those supplying the needs of the maritime industries. Cooperages and ropewalks characterized Sag Harbor in the whaling days. The building of ships and boats became an important industry at Port Jefferson and other north shore towns located near good timber. The development of oystering on a large scale made a new demand

for boats and for repair work. More important was the growth of summer colonies on the shores. The making, repairing and storing of pleasure craft during the winter became an important industry. Here and there, as at Patchogue and Sag Harbor, other manufacturing industries sprang up, and, as the years passed, Brooklyn and Queens became two of the most important industrial centres in the United States.

Recreation.—In the first decade of the 19th century Far Rockaway became a watering place for New York's elite. After the Civil War, with the increase of railroad facilities, Long Island took on an added attraction for the wealthy. Southampton became a second Newport and great estates were built along the north shore. For some distance along the south shore eastward from the city of New York, summer hotels were constructed which by the turn of the century were attracting thousands of summer vacationists. Coney Island, pioneer of U.S. amusement parks, has always flourished, while a major recreational achievement has been the continued development of Jones beach by the Long Island State Park commission; it attracts millions of visitors each summer.

Population.—An outstanding phenomenon after 1950 was the tremendous upward surge of Long Island's population.

The four counties of the island expanded from 5,237,918 in 1950 to 6,403,852 in 1960. Between 1950 and 1960 Nassau county grew from 672,765 to 1,300,171 while Suffolk showed an increase from 276,129 to 666,784. One reason for this expansion in population was the construction of low-priced, one-family housing units in both Nassau and western Suffolk; a prime example is Levittown (pop. [1960] 65,276), developed after World War II as a private investment.

Transportation.—Long Island is served on both shores and through the central part of the island by the Long Island Rail Road, which is reputed to carry more commuters than any other railroad in the country. A highly developed and efficient system of parkways is in operation, while Manhattan is connected with Brooklyn and Queens by the Interborough Rapid Transit and Independent subway lines. Bridges connect the western part of the island with Manhattan and the Bronx; there is direct ferry service from north shore points to Connecticut and from the south shore to Staten Island.

With the advent of the airplane in the early decades of the 20th century, Long Island attracted attention because its flat plains presented ideal conditions for the manipulation of aircraft. By the 1920s Roosevelt field (closed in 1951) and Mitchel air force base (deactivated in 1961) had become internationally known. Both LaGuardia field and John F. Kennedy (formerly New York International, or Idlewild) airport are on the island and the airplane industry there is regarded as the single most important manufacturing enterprise outside the New York metropolitan limits.

(M. H. LE.)

Battle of Long Island, 1776.—The interest of this battle lies in the fact that it was the first engagement in the campaign of 1776 (see AMERICAN REVOLUTION) and was expected in England to be decisive of the contest in the colonies. After the evacuation of Boston (March 1776), Lord Howe moved against New York city, which he thought would afford a better base of operations for the future. The Americans undertook its defense although recognizing the difficulties in the case, as the bay and rivers adjoining would enable the British fleet to co-operate effectively with the army. To protect his left flank George Washington was forced to throw a portion of his troops over to the Long Island side of the East river; they fortified themselves there on the site of the present borough of Brooklyn. Lord Howe, who had encamped on Staten Island at the entrance to the harbour, determined to attack this isolated left wing, and on Aug. 22 landed at Gravesend bay, Long Island, with about 20,000 men. The Americans maintained strong outposts in the wooded hills in advance of their fortified lines. On the morning of Aug. 27 Howe, after four days' reconnaissance, attacked these posts with three columns, the left and centre delivering the holding attack, and the right and strongest column turning the enemy's left by a detour. Howe himself, accompanied by Generals (Sir H.) Clinton and Lord Cornwallis, led the turning movement, which came upon the rear

of the enemy at the moment when they were engaged with the two other columns. By noon the Americans had been driven back into the Brooklyn lines in considerable confusion, and with the loss of about half their number. This constituted the battle. The completeness of the British victory resulted from the neglect of the Americans in guarding the left of their outposts. Howe has been criticized for not immediately assaulting the American works, which he might have carried on the evening of the battle. In view of the fact that he had only defeated a small portion of the American forces, and that the works were of considerable strength, he decided to make a formal siege, and Washington took advantage of the delay in operations to retreat across the river to New York on the night of the 20th. This successful movement repaired to some extent the bad moral effect of the defeat of the 27th in the American camp. In the engagement of Long Island Washington lost 1,200 prisoners, 30 guns, and 400 killed and wounded; of the latter the British lost nearly the same number. (C. F. A.)

LONG ISLAND SOUND, a semienclosed arm of the Atlantic ocean, lies between Connecticut and the island whose name it bears. Its easterly limits are defined by Long Island's Orient Point, and by Plum Island, Great Gull Island, and Fishers Island. The narrow western gateway is at Throgs Neck, where the waters of the sound meet the swift cross currents of the East river. The sound has a length of 90 mi. (78 nautical mi.), a width of 20 mi. (15 nautical mi.) and an area of 1,180 sq.mi. In Pleistocene time, the sound was deepened by two advances of the great Labrador ice sheet which scoured its crystalline bedrock and left two terminal moraines as a dominant feature of Long Island's topography. There is a maximum depth of 330 ft. near the sound's eastern limits, but elsewhere the water is little more than 100 ft. in depth. The mean tidal range is from less than 3 ft. in the east to more than 6 ft. in the west. The drainage basin of the sound is approximately 13 times its area and the annual volume of fresh water is about 35% of its total. Most of this runoff, chiefly from the Housatonic, Connecticut and Thames rivers, enters the sound's relatively open eastern end and is flushed out rapidly to Block Island sound; its effect on the salinity of the sound as a whole is minimal. As this freshened surface layer moves eastward it is replaced by a more saline inflow along the bottom. The relatively shallow waters of the sound are rich in plankton and bottom organisms, which make them favourable for young fish but deter most commercially valuable fish. Except for menhaden, processed for fish meal, the sound does not support an important commercial fishery. The major sports fishing is for weakfish and bluefish. Lobsters, crabs, and clams are caught along the Connecticut shores, and oyster farms are found from Bridgeport eastward. Long Island sound is an important coastal shipping route. Its shores have many residential communities and yachting centres. (W. Wr.)

LONGITUDE: see LATITUDE AND LONGITUDE.

LONGOMONTANUS (CHRISTIAN SEVERIN) (1562-1647), Danish astronomer and astrologer, who is best known for his association with Tycho Brahe and for his published expositions of the Tycho system of the world, was born at Longberg, in Jutland, Den., on Oct. 4, 1562. He is usually known as Christian Longomontanus, from the latinized form of his birthplace. Educated at Longberg and at Viborg, he was employed for eight years (1589-97) by Tycho Brahe at Copenhagen, as an assistant. He was appointed rector of the *Gymnasium* at Viborg in 1603, elected professor in the University of Copenhagen in 1605 and promoted to the chair of mathematics in 1607. Longomontanus began the construction of the Copenhagen observatory in 1632, but he died on Oct. 8, 1647, before its completion. (O. J. E.)

LONGSTREET, JAMES (1821-1904), lieutenant general in the Confederate army during the American Civil War, was born on Jan. 8, 1821, in Edgefield district, S.C., and graduated from the U.S. Military academy at West Point, N.Y., in 1842. He was severely wounded in the Mexican War and was twice brevetted for gallant and meritorious conduct. In 1861, having attained the rank of major, he resigned from the U.S. army when his state seceded, and was named brigadier general in the Confederate army. As a brigade commander, Longstreet won distinction at Blackburn's ford in the first battle of Bull Run. He fought well as a division commander in the Peninsula campaign at Williamsburg, Fair Oaks, and in the Seven Days' battle. At Antietam and Fredericksburg he commanded what was soon called the I corps in Lee's army of northern Virginia. Most of the corps was in southeastern Virginia and in North Carolina when the battle of Chancellorsville took place; but Longstreet, now a lieutenant general, returned in time to participate in the battle of Gettysburg as Lee's second in command. Believing that Lee had agreed to make the campaign offensive in strategy and defensive in tactics, Longstreet strenuously disagreed with Lee's orders to attack at Gettysburg on July 2 and 3, 1863. After a somewhat slow deployment, he assaulted vigorously but with only limited success (see GETTYSBURG). In Sept. 1863 he took part in the battle of Chickamauga, directing the attack that broke the Union lines. In May 1864, back with Lee's army, Longstreet delivered a crushing attack on Grant's left flank at the Wilderness, but a severe wound prevented him from following it up decisively. In Oct. 1864, although paralyzed in the right arm, he resumed command of his corps and handled it ably until the surrender at Appomattox.

During the period of postwar Reconstruction, Longstreet's attitude toward political problems, and the discussion of certain military incidents—notably the responsibility for the Gettysburg failure—made him extremely unpopular. His admiration for Grant and his loyalty to the Republican party accentuated the ill feeling of the Southern people. But in time his services in former days were recalled, and he became once more "General Lee's war horse" to his old soldiers and the people of the south.

Longstreet held several civil offices, among them that of U.S. minister to Turkey under Grant, and later commissioner of Pacific railways. In 1896 he published his reminiscences *From Manassas to Appomattox*. While painfully defensive in tone, the book is useful for historians. Longstreet died on Jan. 2, 1904.

LONGUEVILLE, ANNE GENEVIÈVE DE BOURBON-CONDÉ, DUCHESSE DE (1619-1679), French princess, an extremist successively in social and literary fashion, in politics and in religion, was born on Aug. 29, 1619, at Vincennes, where her imprisoned father, Henry II de Bourbon, prince de Condé, had been joined by his wife, Charlotte de Montmorency. Anne's brothers, Louis, later the Great Condé (q.v.), and Armand, prince de Conti, were born in freedom. When her uncle Henry de Montmorency was beheaded in 1632, she wanted to become a Carmelite, but was dissuaded. Angelically beautiful, she was married in June 1642 to Henry d'Orléans, duc de Longueville (1595-1663). Enthusiastic for preciosity, she became a star visitor of the marquise de Rambouillet. Her husband's mistress, the duchesse de Montbazou (Marie d'Avaujour), had to apologize publicly for alleged misconduct between her and Maurice de Coligny; but Coligny provoked a duel with Mme de Montbazou's friend Henry de Guise in Dec. 1643 and was mortally wounded. From July 1646 to March 1647 Mme de Longueville was abroad with her husband (plenipotentiary at Münster in Westphalia). On her return she resumed a fatal liaison with François, prince de Marillac and later duc de La Rochefoucauld (q.v.). Marillac drew her into political intrigue, but was absent when she and others at Noisy in the autumn of 1648 made the plans that matured in the first war of the Fronde (q.v.). When the royal court left seditious Paris in Jan. 1649, she stayed behind; and when Marillac brought Count

and Longueville to Paris, she went to lodge in the Hôtel de Ville as a surety for their good faith. There she bore the "child of the Fronde," Charles Paris d'Orléans (1649-72), almost certainly Marcellac's.

After the first war Mme de Longueville amused herself in the "Quarrel of the Sonnets," championing Voiture's "Uranie" against Benserade's "Job." In the second war she tried to hold Normandy for her arrested husband's cause, then took refuge in Stenay, treating with the Spaniards. Back in Paris by March 1651, afraid to rejoin her disgruntled husband, she prompted Condé to rebellion; and her relations with the duc de Nemours (C. A. de Savoie) turned La Rochefoucauld's love to hatred. During the third war Condé in March 1652 left her with Conti in Bordeaux. Having abetted the democratic faction there, she had to retire into provincial exile in July 1653. Amnestied by the government and reconciled with Longueville (late 1654), she spent the rest of her life in penitence as the pupil and patroness of the Jansenists. She died at the Carmelite convent of St. Jacques in Paris on April 15, 1679.

(J. G. R.-S.)

LONGUS (between 2nd and 6th century A.D.), Greek writer, was the creator of the pastoral romance and author of *Daphnis and Chloe*. Nothing is known about his life: even his name is suspect, and the only evidence for dating him is the hazardous criterion of stylistic comparison with other authors. His romance, a bucolic idyll in prose, narrates how Daphnis and Chloe, two foundlings brought up by shepherds in Lesbos, gradually fall in love and finally marry. The difficulties, such as abductions, traditionally hindering lovers in this literary genre are severely limited in number and bearing: what interests the author is to describe how the passion of love developed from the first naïve and confused feelings of childhood to full sexual maturity. Longus' psychological analysis, which is penetrating and felicitous, contrasts strongly with the poor characterization in other Greek romances. His descriptions of gardens, landscapes and the alternating of the seasons show a notable feeling for nature, and the atmosphere of pastoral naïveté, which perspicacious critics recognize as artificial, is so dexterously created as to appear natural and convincing to most readers. His short sentences neatly arranged in symmetrical structures aim perhaps at reflecting the style of Alexandrian poetry; in his diction he is a pure Atticist. The general tone of his romance is dictated by the quality prescribed by ancient critics for the bucolic genre—*glykutes*, a "sweetening" of the pastoral life which appealed to the critics of the 18th and early 19th centuries. Bernardin de Saint-Pierre and Salomon Gessner are the best-known imitators of Longus.

Edmonds in the "Loeb Series" (1916). See also E. Rohde, *Der griechische Roman*, 3rd ed. (1914); F. A. Todd, *Some Ancient Novels* (1940); on the manuscript tradition see H. Dörrie, *De Longi, Achillis Tatii, Heliodori memoria* (1935).

(Gr. G.)

LONGVIEW, a city of eastern Texas, U.S., is the centre of a rapidly growing urban area, 126 mi. E. of Dallas, and the seat of Gregg county. It has a large municipal airport and is the principal city of the east Texas oil field, a region with 20,000 producing wells. There are also numerous gas wells and iron-ore deposits in the vicinity, with a fully integrated steel plant located 30 mi. to the north. Longview has petroleum refineries, and plants manufacturing oil-field machinery and equipment, chemicals, paper, plastics, agricultural implements, feedstuff, building materials and photographic supplies. The city's industrial growth has reduced the number of farms in the area, but agriculture is still significant, with many small landowners working part time in the industrial plants. It adopted a commission-manager form of municipal government in 1923. For comparative population figures see table in TEXAS: *Population*.

(N. McG.)

LONGVIEW, a seaport city at the confluence of the Cowlitz and Columbia rivers, in Cowlitz county, Wash., U.S., is about 50 mi. N. of Portland, Ore. Founded in 1922 by R. A. Long, of the Long-Bell Lumber company, on the site of old Monticello, it is one of the world's greatest lumber centres and was the first city of the Pacific northwest to be completely planned with streets,

parks and zoned areas. Longview was dedicated in 1923. A large timber company maintains its largest lumber, paper and pulp mills there, drawing raw material from a 500,000-ac. tree farm.

In addition to Longview's lumber and pulp industries, aluminum, paint, concrete pipes, canned goods, dairy products and fisheries are significant. Nearly 600 ships a year call at the city's public port docks. The Longview bridge, which spans the Columbia and connects Washington and Oregon, is one of the longest cantilever bridges (1,200 ft.) in the U.S. Adjoining Longview to the northeast is the older city of Kelso.

On Nov. 25, 1852, a group of residents of northern Oregon territory held a convention at Monticello to petition congress for division of the territory. This led to the creation of Washington territory in 1853.

For comparative population figures see table in WASHINGTON: *Population*.

LONICERA; see HONEYSUCKLE.

LÖNNROT, ELIAS (1802-1884), Finnish folklorist and philologist, and the compiler of the Finnish national epic *Kalevala* (q.v.). He was born at Sammatti in the province of Uusimaa, on April 9, 1802, the son of a poor country tailor. By perseverance he achieved his doctorate in medicine at Helsinki university (1832). In 1833 he became district medical officer at Kajaani, in a remote part of eastern Finland, near Russian Karelia, where he remained for 20 years. During this time he made 11 expeditions and wrote down extensive collections of traditional folk poetry; and among the Lapps, the Finnish tribes living in the northwest areas of Russia, and the Estonians, he collected material illustrating the mutual relationships of the Baltic branches of the Finno-Ugric languages.

Inspired by Homer, Lönnrot compiled the *Kalevala* on the basis of folklore (1835; 2nd enlarged ed. 1849). He also published a collection of lyrical folksongs, *Kanteletar* (3 vol., 1840-41), and collections of proverbs, riddles and incantations. He was professor of Finnish language and literature at Helsinki university, 1853-62. As a leader of the national revival movement he helped by his extensive publications to make Finnish an official language beside Swedish, which had previously been predominant, and this led to the birth of modern Finnish literature (q.v.). An outstanding achievement was the establishment of a standard Finnish, which took into consideration the different dialects, and its development into a language capable of expressing modern cultural ideas. His Finnish-Swedish dictionary, (2 vol., 1874, 1880), was long one of the most important sources for research into the Finnish language. The prolonged reform of the Finnish hymnbook (1883) also owed much to him.

Lönnrot was a quiet, modest man. In his last decades he became an honoured patriarch, rising above all differences of opinion. He was honorary member of several foreign scientific organizations; e.g., the Paris Ethnological and Philological society and the Academy of Sciences of St. Petersburg. He died at Sammatti on March 19, 1884.

See Aarne Anttila, *Elias Lönnrot*, vol. I (1931), vol. II (1935); introduction to Eng. trans. of *Kalevala* by F. P. Magoun (1963).

(V. Kn.)

LONSDALE, EARLS OF. This English earldom has been held since 1784 by members of the Lowther family (of Lowther in Westmorland), which traces its descent from Sir Hugh Lowther, attorney general in the reign of Edward I. Sir Hugh's descendants included Sir Richard Lowther (1529-1607), who was a supporter of Mary Stuart and was involved in schemes for her rescue from imprisonment in England, and Sir John Lowther, bart. (d. 1706), who developed the port of Whitehaven and the exploitation of the mineral resources of the surrounding area. Sir John's cousin, another Sir John (1655-1700), was created Viscount Lonsdale in 1696.

The 1st viscount's great-grandson JAMES LOWTHER (1736-1802) was created earl of Lonsdale in 1784. Between 1751 and 1756 he succeeded to the estates of three separate branches of the family; in 1751 he inherited the family baronetcy. He married in 1761 a daughter of Lord Bute. Sir James sat in the house of commons almost continuously from 1757 to 1784. Because of his great

wealth, he exercised an enormous influence on elections in the north of England and controlled nine seats in the house of commons, where his nominees were known as "Sir James's ninepins." He died without issue on May 24, 1802, when the earldom became extinct. It was revived in 1807 for his cousin WILLIAM LOWTHER (1757-1844).

William's eldest son WILLIAM (1787-1872), 2nd earl, was postmaster general (1841-45) and lord president of the council (1852). His great-nephew HUGH CECIL LOWTHER (1857-1944), 5th earl (in the second creation), was a flamboyant and well-known sporting personality. Born in London on Jan. 25, 1857, the second son of the future 3rd earl, he succeeded his elder brother in the title in 1882. An expert judge of horses and dogs, Lonsdale was especially interested in hunting, the turf, yacht racing and boxing. It is in connection with the latter sport, through his institution in 1911 (when president of the National Sporting club) of the Lonsdale belts for boxing champions, that his name is chiefly remembered. He died on April 13, 1944. His great-nephew JAMES (1922-), 7th earl, succeeded to the title in 1953.

LONSDALE, DAME KATHLEEN (née YARDLEY) (1903-), English crystallographer, one of the first two women to be elected (1945) to the fellowship of the Royal society, was born on Jan. 28, 1903. She was educated at the University of London, where she earned a D.Sc. in physics. From 1922 to 1927 and from 1937 to 1942 she was research assistant to Sir William Henry Bragg at University college and the Royal institution, London. Between these two periods, she was Amy Lady Tate scholar in the University of Leeds and then Leverhulme research fellow, and afterward, during 1944-46, Dewar fellow at the Royal institution. In 1947 she was special research fellow, United States public health service. She became professor of chemistry at University college, London, in 1949. In 1956 she was created Dame of the British empire and in 1957 was awarded the Royal society's Davy medal in recognition of her distinguished studies. She served as vice-president of the society in 1960-61.

Dame Kathleen Lonsdale's publications include *Structure Factor Tables* (1936), *Crystals and X-Rays* (1949) and many papers in scientific journals. She was also editor of *International Tables for X-Ray Crystallography* (3 vol., 1952-62). Her other interests are reflected in *Quakers Visit Russia* (1952), *Removing the Causes of War* (1953) and *Is Peace Possible?* (1957).

(D. McK.)

LONSDALE, WILLIAM (1794-1871), English geologist and paleontologist, whose studies of fossil corals suggested the existence of an intermediate system of rocks, the Devonian, between the Silurian and Carboniferous systems, was born at Bath on Sept. 9, 1794. He was educated for the army, served in the Peninsular War at the battles of Salamanca and Waterloo, and retired as lieutenant. At his home at Batheaston he collected a series of rocks and fossils which he presented to the Literary and Scientific Institution of Bath. He became the first honorary curator of the natural history department of the museum, serving until 1829 when he became assistant secretary and curator of the Geological Society of London at Somerset House (1829-42). In 1829 Lonsdale read before the society an important paper on the oölitic district of Bath, the results of a survey begun in 1827; later he was engaged in a survey of the oölitic strata of Gloucestershire (1832), and he mapped the boundaries of the various geological formations.

He became the highest authority in England on corals, and he described fossil forms from the Tertiary and Cretaceous strata of North America and from the older strata of Great Britain and Russia. In 1837 he suggested from a study of the fossils of the South Devon limestones that they would prove to be of an age intermediate between the Carboniferous and Silurian systems. This suggestion was adopted by Adam Sedgwick and Roderick (later Sir Roderick) Impey Murchison in 1839, and may be regarded as the basis on which they founded the Devonian system.

Lonsdale's paper, "Notes on the Age of the Limestones of South Devonshire" (read 1840), was published in the same volume of the *Transactions of the Geological Society* (ser. 2, vol. v) with Sedgwick and Murchison's famous paper "On the Physical Structure of Devonshire." Lonsdale died at Bristol on Nov. 11, 1871.

LONS-LE-SAUNIER, a spa of eastern France, capital of the *département* of Jura, lies on the Vallière river 86 km. (53 mi.) S.S.E. of Dijon by road. Pop. (1962) 15,570. The town is surrounded by the vine-clad hills of the western Jura. It owes its name to the salt mines of Montmorot, its western suburb, which have been used from early times. The church of St. Désiré (12th and 15th centuries) has a huge Romanesque crypt. The thermal springs are situated to the southeast, the waters contain salt. Lons-le-Saunier is on the main railway from Basel and Besançon to Bourg and Lyons. Another line runs to Dijon. The principal industry is the manufacture of sparkling wines.

Lons-le-Saunier, known as Ledo in the time of the Gauls, was fortified by the Romans, who added the surname Salinarius to the Gallic name. An object of contention because of the value of its salt, it belonged for a long time during the medieval period to the house of Chalon. It was burned in 1364 by the English, and again in 1637, when it was seized by the duke of Longueville for Louis XIII. It became definitely French in 1674. There the meeting between Marshal Ney and Napoleon took place, on the latter's return from Elba in 1815.

LOO (formerly called LANTERLOO; Fr. *lanturlu*, the refrain of a popular 17th-century song), a game of cards, invariably played for a stake. The players may number from five to about nine, each for himself. The pack of 52 cards is used.

In the simplest form of the game, three cards are dealt to each player, and the next is turned for trump. Eldest hand leads, and one-third of the pool goes to the winner of each trick. The pool is formed by antes before each deal, and may be increased by payments for loo (failure to win a trick) and fines for irregularities.

Among the features added to this base are found:

1. Turn of a card for trump is deferred until the first time any hand fails to follow suit. The trump then fixed affects the winning of the current and any subsequent tricks.

2. The first pool is a single, three counters put in by dealer alone. The players who are loosed pay three counters each to the next pool, making it a double.

3. A player dealt a flush (three trumps) wins the pool without play.

4. The penalty for loo is to double the current pool. This variant, unlimited loo, has caused some considerable fortunes to change hands.

5. The hand may be five cards instead of three: pam, the knave of clubs, is always the highest trump. It may be used as a "wild card" to complete a flush (five cards of one suit) or a blaze (five court cards). The holder of either wins the pool without play.

(G. M.H.)

LOOE, a seaport and urban district of Cornwall, Eng., lies 18 mi. W. of Plymouth by road. Pop. (1961) 3,878. It is divided into East and West Looe by the Looe river, which forms the harbour and is crossed by a seven-arched stone bridge. Above the bridge the river also divides into the East and West Looe rivers. Its streets are narrow, steep and winding, with many ancient, thick-walled houses. The East Looe beach is sandy while the Hannafore beach, on the other side of the river, is largely rocky. The parish church of St. Mary adjoins the sea front at East Looe. Remains of a Benedictine priory and of a Celtic chapel have been found. The harbourage was probably the original cause of settlement at Looe. At the time of the Domesday survey East Looe was assessed under Pendrym, which was of the king's demesne, and West Looe under Hamelin's manor of Trelowia. In the 14th century the former manor was held by the family of Bodrugan, the latter by that of Dauney. In 1237 Henry Bodrugan received the grant of a market on Fridays and a fair at Michaelmas. A charter of incorporation was granted in 1587, and in 1685 James II provided that there should be a mayor and 11 aldermen, 36 free burgesses, four fairs and a court of piepowder (to administer justice at the fairs). East Looe was governed under this charter until 1885. West Looe (known also as Porpighan or Porbuan) was constituted a free borough by a charter ratified in 1325. Upon the attainder of the earl of Devon in 1539 the borough fell to the crown and in 1574 a charter of incorporation was granted providing for a mayor and 11 burgesses, also for a market on Wednesdays and

two fairs. West Looe continued to be administered under this charter until 1869.

Looe was second only to Fowey as a port in the 15th century. It furnished 20 ships for the siege of Calais. A considerable export trade in copper, tin and granite was formerly carried on; the harbour is used by sailing dinghies and other small craft, and by fishing boats. Shark angling has become a major tourist attraction. Looe is also the headquarters of the Spearfishing club of Great Britain. Up the West Looe river is a pilchard canning establishment. Looe Island, $\frac{1}{2}$ mi. from the beach and 1 mi. in circumference, has many legends and is presumed to have been connected with the abbey of Glastonbury.

LOOM: see WEAVING.

LOON (DIVER), name properly restricted to birds of the family Gaviidae, containing four species of the genus *Gavia* and constituting the order Gaviiformes. Measuring about two to three feet in length, they have thick plumage, which in summer is mainly black or gray above and white below, with spots, streaks or bars of white on the upper parts. With the exception of the red-throated loon, *G. stellata*, distinguished by its rich chestnut throat

H. W. HALLIDAY FROM THE NATIONAL AUDUBON SOCIETY

COMMON LOON OR GREAT NORTHERN DIVER (*GAVIA IMMER*) IN SUMMER PLUMAGE

and foreneck (summer plumage), they lose the bold dorsal pattern in winter. They all have a strong, tapering bill; rather small, pointed wings; and legs placed so far back on the body that walking is virtually impossible. The tarsal bones of the ankles are laterally compressed and the first three toes webbed.

Almost wholly aquatic, divers or loons are capable of swimming long distances beneath water and have been known to dive to depths approaching 200 ft. Usually they are found singly or in pairs but may winter in small flocks. The voice is distinctive, consisting of various guttural notes and very loud quavering calls. They feed mainly on fish, crustaceans and insects. The nest usually is a heap of vegetable matter at the edge of water. The eggs, one to three in number, are olive-brown spotted with darker brown.

The loons are wide ranging: the common loon or great northern diver, *G. immer*, of the northern hemisphere, is the most abundant loon in North America; the arctic loon or black-throated diver, *G. arctica*, is circumpolar in distribution, being commonest in the old world; the yellow-billed loon, *G. adamsii*, is found on arctic coasts from Siberia to northwestern Canada. (E. R. Be.)

LOOS, BATTLE OF, the name given to the British share in the Anglo-French offensive in Artois in Sept. 1915, during World War I. This operation, carried out at the request of the French, was conducted by the 1st British army under Gen. Sir Douglas Haig. The attack began early on Sept. 25, 1915, after a four-day artillery bombardment, and was preceded by the release of chlorine gas. Six divisions (47th, 15th, 1st, 7th, 9th and 2nd), forming the I and IV corps, took part. In addition the XI corps (guards, 21st and 24th divisions) was available, but under G.H.Q. and not directly at Haig's disposal.

The attack had some initial success; but exploitation was slow because of the delay in bringing the reserves forward, and subsequent attempts to advance had little success. On Sept. 27, when

the attack had reached a depth of about 8,000 yd., the order to halt was given. Preparations were made to renew the offensive, but these were upset when the Germans counterattacked, with only meagre success, on Oct. 8. Failure was due mainly to the misplacing of the reserves, to shortage of artillery ammunition and to the changing wind's interference with the gas attack. British casualties were 48,200; those of the Germans were estimated at 65,000.

See the British official *History of the Great War—France and Belgium, 1915*, vol. ii (1928).

(C. N. B.)

LOOSESTRIFE, the common name for plants of the family Lythraceae, especially the genera *Lythrum* and *Decodon*, and for two genera of the primrose family (Primulaceae; q.v.), *Lysimachia* and *Steironema*, certain species of which are used as ornamentals. Purple loosestrife (*Lythrum salicaria*), native to Eurasia and naturalized in eastern North America, is a handsome plant growing two to six feet high. It grows on river banks and ditches, and has a branched stem bearing whorls of narrow pointed stalkless leaves and ending in tall tapering spikes of beautiful rose-purple flowers. The flowers exist in three forms, which differ in the relative length of the styles and stamens and are known as long-styled, mid-styled and short-styled forms; the size and colour of the pollen also differ. These differences are important in the pollination of the flower, making self-fertilization next to impossible. (See POLLINATION.) Swamp loosestrife, water willow or wild oleander (*Decodon verticillatus*), a perennial herb native to swamps and ponds of eastern North America, finds some use in the bog garden.

The Eurasian yellow loosestrife (*Lysimachia vulgaris*), an erect plant, two to four feet high, is common on river banks in England and is introduced in eastern North America; the branched stem bears tapering leaves in pairs or whorls, and terminal panicles of rather large deep yellow flowers. Yellow pimpernel or wood loosestrife (*L. nemorum*), a low-growing plant with slender spreading stem and yellow flowers standing singly in the leaf axils, is frequent in England. *L. nummularia* is the well-known creeping jenny or moneywort, a larger plant with widely creeping stem, pairs of shining leaves and large solitary yellow flowers; it is found on banks of rivers and damp woods, and is a common rockery plant. Fringed loosestrife (*Steironema ciliatum*), a yellow-flowered perennial, native to moist parts of North America and naturalized in Europe, is little cultivated but can be used in moist, shady places in the garden.

LOOY, JACOBUS VAN (1855–1930), Dutch author and artist, who most clearly and successfully embodies the naturalist ideal of some of the *Nieuwe Gids* writers and the impressionism of the Hague school of painters, was born at Haarlem on Sept. 12, 1855. In his life he emerged from the insecurity of an upbringing in an orphanage to gain the Prix de Rome in 1883, and in his work this search for self-assurance is marked by the transition from the wistful realism and vivid fantasy of his first short stories in *Proza* (1889) to the neoromantic exuberance of *Feesten* (1902) and the detached humour of his autobiographical stories about the child *Jaapje* (1917), continued in *Jaap* (1923) and *Jacob* (1930). He died at Haarlem on Feb. 24, 1930. (P. K. K.)

LOPBURI, province in the southern part of the central plain of Thailand east of the Chao Phraya river, is watered during the rainy and flood season by the Lopburi river. This river branches off from the Chao Phraya to the east about 20 mi. below Chainat and, after flowing past the cities of Lopburi and Ayutthaya (Phranakhornsri-ayuthya), rejoins the Chao Phraya at Bang Sai. The *changwad* of Lopburi (area 2,544 sq.mi.) had a population of 335,661 in 1960 (density 132 persons per square mile). Soils ill-

JOHN MARKHAM

WOOD LOOSESTRIFE, ALSO CALLED YELLOW PIMPERNEL (*LYSIMACHIA NEMORUM*)

suited for irrigation and rough terrain have helped limit agricultural development. Lopburi (21,232), the capital, is on the Northern railway 75 mi. N. of Bangkok. As an ancient city called Lavo, it was ruled by the Mons during the 7th–8th centuries and by the Khmers during the 10th–13th centuries. After 1665, the Ayutthaya period of Thailand's history, Lopburi became the alternate capital and there the king lived in a royal residence during the rainy season. Lopburi declined after Ayutthaya was sacked by the Burmese and the capital moved to Bangkok. (T. F. B.)

LOPE DE VEGA: see VEGA, LOPE DE.

LOPES, FERNÃO (c. 1380–c. 1460), Portuguese historian, was the first and greatest of the Portuguese royal chroniclers and the most accomplished writer of 15th-century Portuguese prose. He occupies a special place in medieval European historiography because he held that the surest way of arriving at historical truth was through the evidence of historical documents. Nothing certain is known of his early life and his name is first mentioned in 1418, when he was already keeper of the royal archives—a post he long held. In 1434 King Duarte appointed Lopes to write the chronicles of Portugal from the monarchy's origins to the time of John I. The new chronicler prepared himself for his task by studying the contents of the royal archives and by traveling round the kingdom examining monastic and other records, looking at epitaphs and familiarizing himself with the topography of towns and battlefields. When he retired (1454) his history had been completed up to 1411. The last reference to him in contemporary records is dated 1459.

All his chronicles up to the death of Alfonso IV (1357) disappeared from sight early in the 16th century after they had been utilized by Rui de Pina, though what may be an incomplete transcription of them has since been found. There remain intact the short *Crónica de D. Pedro I*, the much more elaborate *Crónica de D. Fernando* and the massive *Crónica de D. João I*, which, though unfinished, runs to nearly 400 chapters. This last was the first of Lopes' works to be printed (1644). Lopes uses documents systematically, sometimes quoting them *in extenso* in his text but, more often, building up a continuous narrative from what he read, particularly in the chancery registers. Since much of this documentary material has now disappeared, the value of Lopes' work as a primary source for Portuguese medieval history can hardly be exaggerated. He also incorporated—particularly in his accounts of the reigns of Ferdinand and John I—material taken from a number of contemporary Portuguese chronicles, most of which have also disappeared. This loss makes a definitive appraisal of Lopes' own work difficult. He is, however, critical of the veracity of some of his predecessors and often corrects them by reference to documents; he acts in a similar way when using the Castilian chronicles of Pedro López de Ayala (*q.v.*) who is, nevertheless, one of Lopes' major sources.

Fernão Lopes writes in a rich, slightly archaic, easy flowing language with a distinct popular flavour, eschewing the displays of erudition and rhetorical device characteristic of other contemporary prose writers. He has a notable ability to handle dialogue realistically and to rise to dramatic moments in his country's history. The main feature of his writing is his desire to leave his readers with a strong visual impression of historical events, though analysis of motive and character is also undertaken. He was of plebeian origin and his approach to history shows marked sympathy with the point of view of the lower orders, whose collective reactions to events are described in masterly fashion. His attitude to the great is notably objective and devoid of flattery. Even his portrait of John I himself—his royal patron's father—is by no means uncritical. He was aware, too, of the importance of economic factors in history: these are given a special place in his account of Ferdinand's reign. Lopes is least convincing when dealing with battles, since he had little, if any, military experience. His intense nationalism caused him, too, to underrate the value of English diplomatic and military support for Portuguese independence in the time of John I. But, in general, he succeeded in his often expressed intention to purvey the whole truth, even when this was not flattering to the Portuguese.

BIBLIOGRAPHY.—The most easily available editions of *Crónica de D.*

Pedro I and *Crónica de D. Fernando* are by D. Peres (1932 and 2 vol. 1933–35 respectively): the best are in *Colecção de livros inéditos de história portuguesa*, vol. iv (1816); *Crónica de D. João I*, ed. by M. Lopes de Almeida and A. de Magalhães Basto, 2 vol. (1945–49); an incomplete transcript of the chronicles up to the death of Alfonso IV which may be by Lopes is to be found in *Crônicas dos sete primeiros reis de Portugal* (1952–53). See also A. F. G. Bell's useful if somewhat out-of-date study, *Fernam Lopes* (1921); P. E. Russell, *Fontes de Fernão Lopes* (1941); A. J. Saraiva, *Fernão Lopes* (1953).

(P. E. R.)
LÓPEZ, CARLOS ANTONIO (1792–1862), second dictator of Paraguay, ended his country's isolation, sought to modernize its economy and society, and became deeply involved in international disputes. Born in Asunción on Nov. 4, 1792, López attended the San Carlos seminary, taught there until it was closed by the dictator José Gaspar Rodríguez Francia (*q.v.*), and then became a lawyer. Exiled to his *estancia* in 1837, López returned to his suburban home when Francia died in 1840. The next year he became the principal of two consuls and in 1844 was elected president with dictatorial powers, an office he held until his death on Sept. 20, 1862.

López amassed a large personal fortune and bestowed favours liberally on his family. Imported foreign technicians built a railway, highways, foundries and modern fortifications. López founded Paraguay's first newspaper, encouraged education and relaxed some of Francia's stern laws. Commerce, agriculture and foreign trade, largely monopolized by the state, improved moderately. At first conciliatory, Pres. Juan Manuel de Rosas of Argentina refused to recognize Paraguay's independence and a brief war occurred (1845–46); relations improved when Rosas was overthrown in 1852. Recognition by several countries followed in 1850, but Paraguay's foreign relations were never smooth. Difficulties with the United States almost resulted in war and neighbouring countries remained unfriendly during most of the López regime.

(H. G. Wn)
LÓPEZ, FRANCISCO SOLANO (1827?–1870), dictator of Paraguay and eldest son of Carlos Antonio López (*q.v.*), seized power upon his father's death in 1862. Born near Asunción on July 24, 1826 or 1827, he received an indifferent education but fancied himself without a peer in military science. A brigadier general at 18, he commanded Paraguay's army in the abortive war with Argentina (1845–46). A few years later he headed a diplomatic mission to Europe during which he purchased munitions, engaged foreign artisans and acquired an Irish mistress, Ellen Lynch. When he became dictator López continued the construction of public buildings and roads and installed the first telegraph system in South America. He devoted most of his time and resources to military preparations until Paraguay had a standing army of more than 60,000, a force López was ready to use to settle boundary and navigation disputes with Brazil and to prevent disruption of the delicate political balance in the La Plata basin. He believed that maintenance of Paraguay's independence and territorial integrity required that he champion nonintervention in Uruguay. On Nov. 12, 1864, less than a month after Brazil intervened in the Uruguayan civil war, López seized a Brazilian merchant vessel and started what became the War of the Triple Alliance. Instead of marching to the aid of his favoured Uruguayan faction, López in December sent an army northward which overran the disputed region of Mato Grosso north of the Rio Apa and captured Corumbá. Reinforced with supplies taken in this campaign, López prepared to attack southern Brazil. When Pres. Bartolomé Mitre refused permission to cross Argentine territory, López seized Argentine ships and attacked Corrientes in April 1865. This move brought Brazil, Argentina and Uruguay together in alliance on May 1. López launched a combined river and land attack in July which resulted in disaster. While the allies prepared to invade Paraguay, López concentrated his forces around the famed fortress of Humaitá which finally fell in July 1867. Thereafter López fought a war of movement, gradually falling back to the north at Paraguay where he was killed on March 1, 1870, at the Aquidauana river. López in 1868 executed several hundred prominent Paraguayans whom he accused of conspiring against him. The war which exterminated more than 300,000 Paraguayans, caused significant changes in demographic and cultural characteristics. López

considered a cruel tyrant, López later was elevated to the pantheon of Paraguayan heroes. (H. G. WN.)

LÓPEZ DE AYALA, PEDRO (1332-1407), Spanish historian, poet and chancellor of Castile from 1398 until his death (in Calahorra), was born at Vitoria. His most impressive works are the chronicles of the four kings under whom he served. After transferring his allegiance in youth from Peter the Cruel to Henry of Trastámara, he held high office under the latter and his successors John I and Henry III, seeing action against the Black Prince at Nájera (1367) and the Portuguese at the disaster of Aljubarrota (1385), where he was taken prisoner. Ayala has been called the first Castilian humanist because of his translations from Boccaccio and Guido da Colonna. As a poet, he is the last representative of the medieval "clerkly craft," and his *Rimado de Palacio*, written largely in the old *cuaderna vía*, is notable for its blistering satire on contemporary society, sparing the mighty of neither church nor state. The chronicles (of which the standard edition is that of 1779-80) display the same powers of implacable observation and vivid expression as the *Rimado*, but substitute for the *saeva indignatio* of the poem an icily impassive surface objectivity even more effective, thanks to Ayala's shrewd choice of significant detail and incident, in conveying his moral judgments.

Ayala's *Poestas* were edited by A. F. Kuersteiner (1920) for the Hispanic Society of America. (F. S. R.)

LÓPEZ DE GÓMARA, FRANCISCO (1512-1557?), Spanish historian, who recorded the deeds of Hernán Cortés, was born in Soria, studied the humanities at Alcalá university and became chaplain in Cortés' household. There he acquired much of the material for his greatest work, the *Historia de las Indias y conquista de Mexico* (1552), the first part of which relates to the discovery and conquest of the Indies and the second part to the triumphs of Cortés. He made Cortés the central figure, giving him all the credit, and his biased account provoked a fellow soldier, Bernal Díaz (*q.v.*), into producing a rival version. His clear, individual style made his work popular, but its partiality caused it to be banned.

LÓPEZ DE MENDOZA, ÍÑIGO, MARQUÉS DE SANTILLANA; see SANTILLANA, ÍÑIGO LÓPEZ DE MENDOZA, Marqués de.

LOP NOR (LOB NOR, Chinese LO-PU-NO-ERH), a lake in Sinkiang Uigur Autonomous Region of China. It lies in the eastern Tarim basin, between the Astin Tagh on the south and the Kuruk Tagh on the north. Ancient Chinese and Greek accounts and maps placed the lake south and east of the great Silk Road station of Lou-lan, at a point about 42° 30' N. lat. About A.D. 330 the lower Tarim river broke out of its old course, turning southeastward, to establish a new terminal water body rather close to the base of the Astin Tagh, causing the abandonment of Lou-lan as a Silk Road station. No medieval European travelers mentioned this change, and European cartographers continued to place Lop Nor in the classical location. In 1876 the Russian explorer N. Prjevalsky discovered two closely connected lake basins 1° S. of the classical site of Lop Nor, which he regarded as being identical with the classical lake.

Several decades of exploratory search for the lake followed. Explorers and geographers engaged in heated debate over the physical history of the Tarim river and Lop Nor. In 1928 Sven Hedin, who had repeatedly sought to solve the puzzle, found both the lower Tarim river and Lop Nor back in their classical positions, the river having returned to its ancient channel in 1921. Hedin's studies made clear that the precise location of the terminal lake had steadily shifted over the centuries, and that the lake varied both in area (about 946 sq.mi.) and in depth.

See Sven Hedin, *The Wandering Lake* (1940). (J. E. Sr.)

LOQUAT (*Eriobotrya japonica*), a subtropical tree of the family Rosaceae, related to the apple and other well-known fruit trees of the temperate zone. It is occasionally called, misleadingly, Japanese plum and Japanese medlar, but these names are gradually disappearing. The latter name refers to its resemblance to the closely related medlar (*q.v.*).

Though its native home is probably central-eastern China, the loquat tree was introduced very early into Japan, where it was

much developed horticulturally and is still highly valued. Some superior Japanese varieties eventually reached Europe, the Mediterranean basin and a few other regions. The loquat is grown commercially (usually on a rather small scale) in many subtropical regions. It is not adapted to the tropics, except at elevations where the climate is cool. In Mexico the tree is known as *nispero del Japón*.

Ornamental in appearance and rarely more than 30 ft. in height, the evergreen loquat is frequently planted in parks and gardens. The leaves, which are clustered toward the ends of the branches, are thick and stiff, elliptic to lanceolate in form, eight to ten inches long, with coarsely serrate margins. The small fragrant white flowers are arranged in dense terminal panicles. The fruits are borne in large loose clusters; individually they are round, obovoid or pear-shaped, one to three inches in length, with a tough, yellow to bronze plumlike skin enclosing juicy, whitish to orange-coloured flesh surrounding three or four large seeds. The flavour is agreeably tart, suggesting that of several other fruits of the same family.

While the loquat is commonly grown from seeds, commercial plantings are usually based on grafted trees of superior varieties, such as Tanaka of Japanese origin, Gold Nugget, Champagne and Early Red of California. Propagation is by shield budding and cleft grafting; loquat seedlings or quince rootstocks grown from cuttings can be used, the latter if a dwarf tree is desired.

When planted in orchard form, the trees are spaced 20 to 25 ft. apart. They grow well on various soils, from sandy loams to clays, and come into bearing at an early age, three or four years.

See Wilson Popenoe, *Manual of Tropical and Subtropical Fruits* (1920); W. H. Chandler, *Evergreen Orchards*, 2nd ed. (1958). (W. Po.)

LORAIN, a city of Ohio, U.S., in Lorain county, is a port on the Great Lakes. Its harbour, the lower 3 mi. of the Black river, is on the south shore of Lake Erie, 25 mi. W. of Cleveland and 70 mi. E. of Toledo. The city occupies the level terrain on both sides of the river to and beyond the head of navigation.

In the early 19th century the area was occupied by Indians. Title to the Connecticut Western Reserve district passed to the Connecticut Land company with the signing of the treaty of Fort Industry in 1805. The territory was then surveyed and opened for settlement under the name of Mouth of Black River. The village was first incorporated as Charleston in 1836. It declined in importance and lost its charter after Cleveland was selected as the terminus of the Ohio and Erie canal and when the westward extension of the railroad was routed through Elyria, leaving Charleston's port without rail connections with the interior. When the Poe lock at Sault Sainte Marie, Mich., was opened in 1896 and the Cleveland, Lorain and Wheeling railroad (later part of the Baltimore and Ohio) to the coal fields of southeastern Ohio was completed in 1872, the coal and iron ore trade was established. The town was rechartered in 1874 as Lorain because the U.S. post office had approved another Ohio town as Charleston.

In 1890 the Johnstown Steel company was located on 3,000 ac. of land at the head of navigation on the Black river. This company was chiefly responsible for the city's growth. Other manufacturing industries include shipbuilding, power shovels, cranes, bearings, steel stampings, car and truck assembly, railroad shops, gypsum lath and wallboard, and clothing. Coal averages 98% of all water-borne shipments, and iron ore and limestone constitute 95% of total receipts of the port of Lorain. About 50% of the iron ore and limestone are used locally.

Lorain is a cosmopolitan city with large population segments of Puerto Ricans, Hungarians, Poles, Germans, Italians, Czechoslovaks and Slovenians. Five public parks comprising 171 ac. provide recreational facilities. Population (1960) 68,932; Lorain-

Elyria standard metropolitan statistical area (Lorain county), 217,500. For comparative population figures see table in OHIO: Population. (R. B. FR.)

LORANTHACEAE, the mistletoe family, containing 25-30 genera and more than 600 species in tropical and temperate regions. All the members of this dicotyledonous family are partially parasitic plants; their greenish leaves are capable of making some food of their own. Most are evergreen herbs or shrubs found attached to the branches of trees. In the United States the family is represented by about six species of *Phoradendron* (American mistletoe) and about eight species of *Arceuthobium* (pine mistletoe). The only British species is *Viscum album*, the mistletoe of history. *Nuytsia floribunda*, the so-called parasitic Christmas tree or mistletoe tree of western Australia, is remarkable in being the only terrestrial and treelike (up to 35 ft. high) member of the family. See MISTLETOE; NUYTSIA.

LORCA, FEDERICO GARCÍA: see GARCÍA LORCA, FEDERICO.

LORCA, a town of the province and region of Murcia, south-eastern Spain, is situated on the Guadalentín river 62 km. (38½ mi.) S.W. of Murcia by road. Pop. (1960) 58,641 (mun.). It is in a semiarid and steppelike area surrounded by rugged mountains. The town, which is divided in two by the Guadalentín, has many fine houses with coats of arms on the walls. The old part surrounds the castle; the modern part is centred on the Calle de la Corredera. The industrial area of San Cristóbal is on the other side of the river. The farming district is San Juan. Cattle fairs are held in the Santa Quiteria suburb. Lorca is on the railway from Granada to Murcia and Valencia. Cereals are the main crop. Irrigation has been practised since the time of the Muslim invasion. Water is bought and sold all the year round in the Casa del Alporchon. The pasture lands support cattle, sheep, mules and donkeys. There are factories manufacturing hemp sandals. The town was the Ilukro of the Romans and the Muslim Lurka. It was reconquered in 1234 and became a Christian stronghold.

(M. B. F.)

LORD, in its primary sense, the head of a household, the master of those dependent on him for their daily bread; the word frequently occurs in this sense in the Bible. As a term implying the ownership of property, "lord" survives in "lord of the manor" and "landlord." It is not only a general word for a prince or sovereign but also a common word for a feudal superior, and particularly for a feudal tenant holding directly of the king, a baron (*q.v.*). Hence in Britain lord denotes a peer of the realm, a member of the house of lords, which includes the lords temporal and the lords spiritual; this is the chief modern usage. The prefix "lord" is ordinarily used as a less formal alternative to the full title, whether held by right or by courtesy, of marquess, earl or viscount, and is always so used in the case of a baron (particularly in the peerage of Scotland where it remains the only correct usage at all times.) Where the name is territorial the "of" is dropped, thus "the marquess of A.," but "Lord A." The younger sons of dukes and marquesses have, by courtesy, the title of lord prefixed to the Christian and surname, *e.g.*, Lord John Russell. In the case of a diocesan bishop his proper title is the Lord Bishop of A., whether he be a spiritual peer or not. Some high officials of the cabinet have the word "lord" prefixed to their titles, *e.g.*, first lord of the treasury (the prime minister), lord high chancellor, lord president of the council, lord privy seal, etc. In certain cases the members of a board which has taken the place of an office of state are known as lords commissioners, *e.g.*, lords of the treasury, civil or naval lords of the admiralty.

For lord lieutenant and lord mayor (the title given to the mayors of certain large cities in England) see LIEUTENANT and MAYOR. The form of address, "my lord," is properly used not only to those members of the nobility to whom the title "lord" is applicable and to bishops but also to all judges of the high court in England and lord provosts. (S. B.-R. P.)

LORD ADVOCATE, or queen's advocate, the principal law officer of the crown in Scotland. His business is to act as a public prosecutor, and to plead in all causes that concern the crown. He is the head of the administration of criminal justice, and thus his

functions are much more extensive than those of the English law officers. He is aided by a solicitor general and four advocates-depute. The office seems to have been established about the beginning of the 16th century, but it was only in the year 1597 that the holder was empowered to prosecute without the concurrence of a private party. He has the privilege of pleading in court with his hat on. See also SCOTLAND: Administration and Social Conditions: Justice.

LORD CHAMBERLAIN, an important officer of the British royal household, to be distinguished from the lord great chamberlain (*q.v.*), whose office also evolved from that of the chamberlain (*q.v.*) at the Norman court. The office of lord chamberlain, unlike that of the lord great chamberlain, is not hereditary, but it is always held by a peer and a privy councillor. Formerly he was a member of the government, appointed by the prime minister, and before 1782 the office carried cabinet rank. In 1924, when the first Labour government was in power, it was decided the office should be nonpolitical and the holder should be appointed by agreement between the sovereign and the prime minister.

The lord chamberlain is the second dignitary of the court. On ceremonial occasions he carries a white staff and wears a golden or jeweled key representing the key of the palace, which is supposed to be in his care. He does, in fact, control the state apartments at Windsor castle and at St. James's palace. He is in charge of all court ceremonial and of the arrangements for all state ceremonies, such as the state visits of foreign dignitaries, royal marriages, christenings and funerals except that of the sovereign, which is the responsibility of the earl marshal (*q.v.*). He also organizes the royal garden parties, where he is in close personal attendance on the sovereign. He has an office in St. James's palace where he is assisted by a staff under a comptroller and an assistant comptroller.

At one time the lord chamberlain discharged important political duties, but these are now mainly confined to presenting addresses from the house of lords to the sovereign and conveying the reply to them. The same duty is performed for the house of commons by the vice chamberlain, whose office is still a political appointment. The vice chamberlain is a member of the government of the day, usually one of the junior whips. Like the lord chamberlain, he carries a white staff as a badge of office on ceremonial occasions.

The lord chamberlain is the head of the royal household and is responsible for the ecclesiastical and medical households, the honourable corps of gentlemen at arms and the sovereign's bodyguard of the yeomen of the guard. Under him, too, are such varied officials as the surveyors of the sovereign's pictures and works of art, the librarian of the royal library, the poet laureate, the master of music, the bargemaster and watermen, and the keeper of the royal swans. When any article of the regalia is required for a state ceremony, such as the opening of parliament or the distribution of the royal maundy, it is the lord chamberlain who issues the necessary instructions to the keeper of the jewel house at the Tower of London. On the more ceremonial side the marshal of the diplomatic corps, the officials of the central chancery of orders in knighthood whose province it is to regulate investitures, and the gentlemen ushers and sergeants at arms also come under the lord chamberlain's office. Of the gentlemen ushers the principal usher is the gentleman usher of black rod, who derives his title from the black rod which he carries as the badge of his office. Black rod is an officer of the Order of the Garter, and is in constant attendance at the house of lords, where it is part of his duty to carry messages and summonses to the house of commons. It is he, for instance, who is sent at the opening of parliament to summon the members of the house of commons to attend the upper house in order to hear the speech from the throne.

The lord chamberlain is also chairman of the committee that recommends for the sovereign's consideration applications for the grant of the royal warrants of appointment for the supply of goods. One curious but important part of his duties is the licensing of London theatres (which includes fire precautions, etc.) and the censorship of stage plays throughout the United Kingdom. This dates back to the reign of Queen Elizabeth I when the lord cham-

berlain was in charge of all court entertainments and took the players under his personal protection. To assist him in the censorship there are three examiners who advise on plays submitted to them.

When there is a queen consort or a queen mother, she has her own lord chamberlain, treasurer, mistress of the robes and ladies in waiting. See also **HOUSEHOLD, THE ROYAL; CHAMBER, KING'S.**

BIBLIOGRAPHY.—A. A. Mitchie, *The Crown and the People* (1952); T. F. Tout, *Chapters in the Administrative History of Mediaeval England*, 6 vol. (1920–33); Dorothy Laird, *How the Queen Reigns* (1959). (L. E. TA.)

LORD CHIEF JUSTICE OF ENGLAND is the head of the queen's bench division of the high court of justice and next in rank to the lord chancellor. He usually presides over the court of criminal appeal, is *ex officio* a member of the court of appeal, and is appointed by the crown on nomination of the prime minister. He is invariably raised to the peerage on appointment, and so is able to take part in the appellate work of the house of lords; and although, like all other judges except the lord chancellor, he must not form public associations with any political party, the lord chief justice may (as Lord Goddard did when he held the office) intervene in debates on legal and judicial problems. His title was conferred upon him by the Judicature act, 1873, by which the court of queen's bench became one of the divisions of the queen's bench division. See also **JUDICIARY AND COURT OFFICERS.**

LORD GREAT CHAMBERLAIN, who must be distinguished from the lord chamberlain (*q.v.*), is one of the great English officers of state. His office dates from Norman times, when, as his name implies, he was specially connected by his duties with the king's chamber (see **CHAMBER, KING'S**), and he was originally the financial officer of the household. As he was always a great baron, deputies performed his financial work (see **CHAMBERLAIN: England**), and his functions became, as they are now, mainly ceremonial though the emblem of his office is still a key.

From its creation in the 12th century until 1779 the office was held by the De Veres, earls of Oxford. It then passed to co-heiresses. In 1962 the holder was the marquess of Cholmondeley, in whom the office was vested jointly with the earl Ancaster and the heirs of the late marquess of Lincolnshire.

The lord great chamberlain has charge of the palace of Westminster, especially of the house of lords, and when the sovereign opens parliament in person he is responsible for the arrangements. He assists at the introduction of peers into the house of lords on their creation. At coronations he emerges into special importance, and takes an active part in investing the sovereign with the royal insignia.

See G. E. C., *The Complete Peerage*, vol. x, appendix F, "The Office of Lord Great Chamberlain of England," pp. 46–90 (1945). (L. E. TA.)

LORD HIGH CHANCELLOR, a British officer of state with three main functions: he presides over the house of lords; he is the head of the judiciary; he is also a minister, a member of the government and of the cabinet, having under his control all the judicial appointments in the country except those reserved to the prime minister, and a great deal of ecclesiastical patronage.

This miscellany of duties and powers are united in one person for reasons that lie deep in history. In England the office of chancellor dates back to St. Edward, the Confessor, who, in making this appointment, followed the model of the Carolingian court. Until the 14th century the chancellor was invariably a priest; he was at once a royal chaplain, the king's secretary in secular matters and keeper of the royal seal. This combination of duties, characteristic of the primitive administrative systems of the early middle ages, has left its imprint on the chancellorship to the present day: as chaplain the chancellor was keeper of the king's conscience, as secretary he was the king's closest confidant in secular matters and as keeper of the seal he played a necessary part in all formal expressions of the king's will. By him and his staff of chaplains the whole secretarial work of the royal household was conducted, the accounts were kept under the justiciar and treasurer, writs were drawn up and sealed and the royal correspondence was carried on. The chancellor was, in fact, as the historian Bishop

Stubbs put it, a sort of secretary of state for all departments.

From the 12th century until the early Tudor period the chancellor wielded immense power, especially during an interregnum or the king's absence abroad. Among notable chancellors were Roger (d. 1139), bishop of Salisbury, who organized the exchequer in the reign of Henry I, and Thomas Becket (d. 1170), who held the office before Henry II made him archbishop of Canterbury. In the reign of Richard I, Archbishop Hubert Walter (d. 1205) achieved particular prominence because of the king's prolonged absences. Robert Burnell (d. 1292) was Edward I's most trusted and influential minister, while tenure of the office contributed greatly to the power and self-importance of the cardinals Henry Beaufort (d. 1447) and Thomas Wolsey (d. 1530).

The chancellorship in England developed on different lines from the chancellorship in the Holy Roman empire and, later, the Austrian and the German empires; there the chancellors, as exemplified by Metternich and Bismarck, remained up to modern times the effective heads of government, as is the chancellor in the Federal Republic of Germany (see **CHANCELLOR**). The reason for the difference lies in the development in England of the judicial duties of the chancellor. These grew out of the fact that all petitions addressed to the king passed through the chancellor's hands. Already in the reign of Henry II the chancellor was largely employed in judicial work. The office acquired a more definitely judicial character when, in the reign of Edward III, the chancellor's court ceased to follow the king; and the time when, in the middle of this reign, all petitions that were matters of grace were definitely committed to the king may be taken as the start of the equitable jurisdiction of the chancellor (see **EQUITY**). The chancellor's court was the direct precursor of the court of chancery, which, by the Judicature act, 1873, was fused into the high court of justice, the chancery division of which is primarily responsible for that court's equitable jurisdiction. The lord chancellor is the president of the chancery division; he is a member of the court of appeal and, if present, presides over it.

The judicial work of contemporary chancellors is, however, almost exclusively confined to the house of lords and the judicial committee of the privy council (*q.v.*); when the chancellor is present, he presides over both tribunals, though, because of the weight of administrative business, modern chancellors seem to have less time for their judicial duties than had their predecessors before 1939.

The position of the chancellor as speaker or prolocutor of the house of lords dates from the time of the English Norman kings, when the ministers of the royal *curia* (the king's court) formed *ex officio* a part of the *commune concilium* (the great council) and parliament. The chancellor originally attended with the other officials, and he continued to attend *ex officio* after they had ceased to do so. The chancellor attends the house of lords by virtue of his office, but he has generally, and since the reign of Queen Anne invariably, been a peer. There have been times when the great seal has been put into commission and other times when its custody has been transferred from the chancellor to a minister with the title of lord keeper of the great seal (*q.v.*). By the Act of Union (1707) of England and Scotland one great seal was appointed to be kept for all public acts; the chancellor's authority thus extends to the whole of the United Kingdom, and the commissions of the peace for Scotland as well as for England issue from him. By the Roman Catholic Relief act, 1829, it was enacted that no Roman Catholic was to be appointed lord chancellor or keeper or commissioner of the great seal.

As speaker of the house of lords, the chancellor's powers and duties differ considerably from those of the speaker of the house of commons. He puts the question but has no power to rule upon points of order. Like the speaker of the house of commons, he may take part in debates, and, unlike modern speakers, chancellors frequently do so.

See also **MINISTRY, GOVERNMENT.**

(W. T. Ws.)

LORD HIGH CONSTABLE: see **CONSTABLE.**

LORD HIGH STEWARD. In England the lord high stewardship of the later middle ages looks back to the grants of the stewardship of England and Normandy by the future Henry

II as duke of Normandy in 1153 to Robert earl of Leicester (d. 1168) and his son Robert (d. 1190). The death of the next earl without male heir in 1204 caused the office to fall into desuetude until it was revived for Simon de Montfort who served as steward at Queen Eleanor's coronation in 1236. The office was mainly honorific (*see* HOUSEHOLD, ROYAL). On Simon's death at the battle of Evesham in 1265 his forfeited lands were given to Henry III's younger son Edmund, earl of Lancaster, who held the stewardship for life. Soon after his coronation in 1308, Edward II conferred the office on Edmund's son Thomas, and his heirs.

Its annexation by the most acquisitive branch of the royal family accounts for the peculiar importance of the office in the hands of John of Gaunt, duke of Lancaster, who assumed control over the minor, Richard II. By the duke's order the minutes of proceedings held before him on the claims to take part in the coronation ceremonies were enrolled. The judgments became precedents for the court of coronation claims held before the steward. In the mid-20th century this court is still held before coronations, but is presided over by commissioners. In 1397 John of Gaunt established another notable tradition by presiding as lord high steward at the trial before parliament of the earl of Arundel and others. The lord high stewardship ceased to be a permanent post in 1421 with the death of Thomas of Lancaster, duke of Clarence. Thereafter a steward was appointed only to preside over the court of claims, to perform certain ceremonial duties at the following coronation and, in certain cases, to act as judge at the trial of a peer (*see* below). Nowadays the lord high steward fulfills only the second of these functions.

The general principle of judgment by peers embodied in Magna Carta strengthened the claim of the lords in parliament that they should not be tried by the ordinary courts for serious crimes. The history of the trial of lords for treason is obscure (*see* IMPEACHMENT), but it became established that if such a trial were held during a parliamentary session the lords sat in the ancient traditional manner of a court of justice under the presidency of the lord steward. The peers who were members of the court were the judges, and each, including the president, individually pronounced his judgment on the accused. The lord steward presided in the manner that a feudal lord's steward had presided over the court of his lord's vassals. If parliament were not in session, the trial was held before the lord high steward sitting as a true judge, the peers acting as a jury who must give a unanimous verdict. For each trial a special commission was issued appointing a lord high steward. In accounts of such trials he is described throughout as "His Grace," and at the end of the trial his rod or staff of office was handed to him by the gentleman usher of black rod to be broken by the steward as a sign that his office had ended. It was in the lord high steward's court that the supposititious duchess of Kingston was tried for bigamy in 1774, and that the earl of Cardigan was tried for attempted murder by shooting in 1841. The most recent examples are the trials of Lord Russell in 1901 and Lord de Clifford in 1935. The procedure was abolished by the Criminal Justice act of 1948.

See T. F. T. Plucknett, *A Concise History of the Common Law*, 5th ed. (1956); L. W. Vernon-Harcourt, *His Grace the Steward and the Trial of Peers* (1907). (D. M. S.)

LORD HIGH TREASURER. In England, the late Saxon kings had their treasury at Winchester and the first man known to bear the title of treasurer had a house in the city before the Norman Conquest. Winchester remained the royal treasury through the 12th century with subordinate treasuries in royal castles such as Salisbury for the king's convenience as he moved about the land. The offices of treasurer and chamberlain in Henry I's reign were sometimes held by the same man, but the establishment of the exchequer (*q.v.*) and the rapid increase of business meant that the offices could not long be combined. The treasurer became responsible for the working of the exchequer at Westminster and before the end of the 12th century was continually occupied there. He was represented in the treasury by his clerk. The continuous history of the office begins with the appointment early in Henry II's reign of Richard Fitzneale (*q.v.*), son of Bishop Nigel of Ely. Near the end of his long tenure of the treasurership he wrote the

Dialogus de Scaccario, a description of the working of the exchequer with which the history of English financial organization effectively begins. In Henry III's reign the treasurer ranked with the justiciar (*q.v.*) and the chancellor (*q.v.*) as one of the three great officers of state. The titles "lord treasurer" and "lord high treasurer" came into general use in the 16th century and were used continuously from 1612 when the office was first put in commission (*i.e.*, the duties were relegated to a specially chosen board). The Restoration (1660) was followed by important changes, and the commissioners appointed in 1667 controlled a newly ordered treasury organization which was distinct from the exchequer and more independent of the privy council than previously. The office was in commission intermittently until 1714 and permanently thereafter. From 1690 to 1841 the first commissioner, or lord of the treasury, if not a peer of the realm, was also chancellor of the exchequer and finance minister; if he was a peer, the chancellorship was ordinarily held by a member of the house of commons. In the mid-20th century the prime minister is the first lord and the chancellor of the exchequer the second lord of the treasury. The five junior lords who make up the rest of the board are government whips. *See* also CHAMBER, KING'S; GOVERNMENT DEPARTMENTS.

See F. M. Powicke and E. B. Fryde, *Handbook of British Chronology*, 2nd ed. (1961), which gives a list of treasurers and a full list of sources for the history of the office. (D. M. S.)

LORD HOWE ISLAND, in the southern Pacific ocean, is 436 mi. N.E. of Sydney, Austr., in longitude 159° 5' E. and latitude 31° 30' S. Pop. (1961) 249. The island measures about 7 mi. by 1 mi., is well wooded and rises to 2,840 ft. in Mt. Gower at the southern end. It is of volcanic origin, and the coral reefs on its western shore are the most southerly known. Discovered in 1788 and now governed by a board in Sydney, the island is mainly a tourist resort. The atoll Ontong Java in the Solomon Islands was also formerly called Lord Howe Island. (O. H. K. S.)

LORD JUSTICE CLERK, in Scotland, the judge next in rank to the lord justice-general (*q.v.*). He presides in civil cases in the second division of the court of session, and in the absence of the lord justice-general, in criminal cases in the court of justiciary. Like the master of the rolls he was originally not a judge at all, but clerk and legal assessor of the justice court. In time he was raised from the clerk's table to the bench, and by custom presided over the court in the absence of the justice-general. Up to 1672 his position was somewhat anomalous, as it was doubtful whether he was a clerk or a judge, but an act of that year, which suppressed the office of justice-depute, confirmed his position as a judge, forming him, with the justice-general and lords commissioners of justiciary, into the court of justiciary. The lord justice clerk is also one of the officers of state for Scotland, and one of the commissioners for keeping the Scottish regalia.

LORD JUSTICE-GENERAL, the highest judge in Scotland, head of the court of justiciary (the highest criminal court), called also the lord president, and as such head of the court of session (the supreme civil court) and representative of the sovereign. The office of justice-general was for a considerable time a sinecure post held by one of the Scottish nobility, but by the Courts of Session act, 1830, the office was united with that of lord president of the court of session, who then became president judge of the court of justiciary. *See* also SCOTS LAW.

LORD KEEPER OF THE GREAT SEAL, in England, formerly a great officer of state. The great seal of England, which is affixed on all solemn occasions to documents expressing the pleasure of the sovereign, was first adopted by Edward the Confessor (*see* SEALS), and entrusted to a chancellor for keeping. The office of chancellor from the time of Becket onward varied much in importance; the holder being an ecclesiastic, he was not only engaged in the business of his diocese but sometimes was away from England. Consequently, it became not unusual to place the personal custody of the great seal in the hands of a keeper; this, too, was the practice followed during a temporary vacancy in the chancellorship. This office gradually developed into a permanent appointment, and the lord keeper acquired the

right of discharging all the duties connected with the great seal. He was usually, though not necessarily, a peer, and held office during the king's pleasure; he was appointed merely by delivery of the seal, and not, like the chancellor, by patent. His status was definitely fixed (in the case of lord keeper Sir Nicholas Bacon) by an act of Elizabeth I, which declared him entitled to the same powers and jurisdiction as the lord chancellor. Subsequently he was generally raised to the chancellorship, and retained the custody of the seal. The last lord keeper was Sir Robert Henley (afterward 1st earl of Northington), appointed in 1757 and made lord chancellor in 1761.

See also CHANCELLOR; LORD HIGH CHANCELLOR.

See F. M. Powicke and E. B. Fryde, *Handbook of British Chronology*, 2nd ed. (1961), which gives a list of keepers; H. C. Maxwell-Lyte, *Historical Notes on the Use of the Great Seal* (H.M.S.O., 1926).

(SN. G.)

LORD PRESIDENT OF THE COUNCIL, in England, one of the great officers of state and a member of the ministry who formally directs the privy council. It was only in 1679 that the office of lord president became permanent; previously either the lord chancellor, the lord keeper of the seal, or some particular court official carried out the duties.

The office was of greater direct importance when the powers of the privy council, exercised through various committees, were of wider extent than at the present time (see PRIVY COUNCIL). The duties of the office are to preside over the meetings of the privy council and to draw up the minutes of council upon subjects which do not belong to any other department of state. In modern times the lord president was, until the appointment of a minister for science, to a large extent a minister of science, since the department of scientific and industrial research and the departments responsible respectively for medical and industrial research came under his control. The office is very frequently held in conjunction with other ministerial offices. The lord president is generally a member of the house of lords, and is included in the cabinet.

LORD PRIVY SEAL, the officer in the British government who has custody of the privy seal. See SEALS.

LORDS JUSTICES OF APPEAL: see JUDICIARY AND COURT OFFICERS.

LORDS OF APPEAL IN ORDINARY: see JUDICIARY AND COURT OFFICERS.

LORD'S PRAYER (Lat. ORATIO DOMINICA or PATER NOSTER) perhaps from the beginning was meant as that unifying bond it has become in Christendom. The Jews had their daily prayers and "sectarians" had theirs. Luke xi, 1 gives the Lord's Prayer as such a prayer, and it resembles Jewish prayers with their three elements of praise, petition and yearning for God's Kingdom ("May his great name be . . . hallowed . . . May he establish his Kingdom in your days"). The Lord's Prayer, however, shows greater economy of words (cf. Matt. vi, 7). The Lucan form (Luke xi, 2-4), in the better manuscripts, is shorter and often considered more original; yet it shows signs of theological reflection, while the Matthean form (Matt. vi, 9-13), that universally used, has more liturgical features, not to be held against its originality.

Roman Catholics say the Lord's Prayer without the doxology ("for thine is the Kingdom . . .") used in the rest of Christendom. Roman Catholic usage agrees with the best manuscripts; but it is known from Jewish prayers that a prayer ended with a freely chosen doxology. One of these occurs in the version of the prayer given in the Didache (viii) and made its way into the later biblical texts. "Trespases" (Tyndale's Bible and the Book of Common Prayer) and "debts" (King James version and Revised Standard version) are different translations of a word meaning "that which one owes" (probably to one's brother in the community; cf. Matt. xviii, 15).

Used three times daily by the 2nd century (Didache, viii, 3), the Lord's Prayer found its place at the centre of the Mass and all services. With the Apostles' Creed (see CREED) it formed the nucleus of medieval devotional practice and catechism, as retained, e.g., by Luther. By the early 3rd century Origen and

Tertullian had woven theological tractates around it, but the attempts to reach back to its original meaning began with the recognition of eschatology (q.v.) as the frame for the teaching of Jesus. In that light the prayer becomes a meaningful unity and its petitions take on precision. A radical eschatological interpretation would in paraphrase read somewhat like this:

Hallowed by thy name among the nations [cf. Ezek. xxxvi, 23] by the coming of the Kingdom and by the manifestation of thy plan of salvation on earth as it is now realized in heaven.

Give us today the foretaste of the heavenly banquet [daily bread; rather, the bread for the morrow; Matt. viii, 11].

And forgive us what we have done against our brethren as we have forgiven those who have wronged us.

And cause us not to suffer the utmost trial [cf. Matt. xxiv, 22], but deliver us from evil [or, the Evil one].

While differing in details, most scholars agree that the original meaning of the Lord's Prayer is to be sought in such a direction; there lies the common denominator for later interpretations and the impetus for new insights in the life of Christian prayer.

See also PRAYER.

(K. St.)

LORD'S SUPPER, a title of the Eucharist, the central rite of Christian worship, instituted by Jesus at the Last Supper on the night before his crucifixion. St. Paul alone among the writers of the New Testament used the term "Lord's Supper" (I Cor. xi, 20), as he alone used the term "communion" or "participation" in this sense (I Cor. x, 16). From the 2nd century on, Christian writers generally preferred the title "Eucharist." See EUCHARIST.

LORD STEWARD, in England, an important official of the royal household who is not to be confused with the lord high steward (q.v.), one of the great officers of state. Both offices evolved from that of the early medieval steward, or seneschal, during the 13th century. The duties of the lord steward were originally domestic, and he was known as the "chief steward" of the household (first recorded in 1293). In the *Ordinances of Eltham* (1526) he is called "the lord great master," and in 1554, at the request of Queen Mary I, the name was changed by act of parliament to the present title "Lord Steward of the Queen's most honourable Household." The office was of considerable political importance under the Tudors and Stuarts, and up to 1782 it carried cabinet rank. Until 1924 it continued to be a political appointment which was bestowed on a member of the government. Since that date the office has been filled at the discretion of the sovereign. In theory the lord steward is responsible for the day-to-day management and the financial affairs of the royal household; in practice these duties were assumed by the master of the household when the prince consort reorganized the household in the 1840s. A further change took place in 1920 when the executive and some of the ceremonial duties of the lord steward were transferred to the lord chamberlain (q.v.). In consequence, the functions of the lord steward are now purely ceremonial and are mostly confined to state occasions, when he bears a white staff as the badge of his office. He is still the first dignitary of the court and is always a peer and a privy counselor. (See also HOUSEHOLD, ROYAL.)

In the past, the lord steward also had legal and judicial authority. He presided over the counting house, or Board of Green

Cloth (as it came to be called in Tudor times), a name derived from the green-covered table at which its transactions were originally conducted, where together with the cofferer and others he controlled the expenditure and made the necessary provisions for the royal household. The board also had "power to correct all offenders, and to maintain the peace of the immediate verge or jurisdiction of the court-royal, which extends every way two hundred yards from the gate of the palace" where the sovereign might happen to reside for the time being. The functions of the Board of Green Cloth are now largely nominal. It meets annually to license, on behalf of the sovereign, public houses within the verge (*i.e.*, 12 mi. radius) of the old Palace of Whitehall. The audit of household civil-list accounts is now conducted by the treasury.

From the turn of the 13th century the lord steward also presided over the lord steward's court, which had jurisdiction over offenses and felonies committed by the king's servants (this jurisdiction was extended in 1541 to cover treasons, murders and manslaughters or offenses where blood was shed), and over the Marshalsea court, a court of record held before the lord steward and the knight marshal of the household, which had civil and criminal jurisdiction over any action within the verge where at least one of the parties was a member of the royal household. In 1630, King Charles I, by letters patent, established a new court of record, called the palace court, under the lord steward and the knight marshal. Its powers were renewed in 1665 with jurisdiction over all actions arising between parties within the verge, the jurisdiction of the Marshalsea court, the City of London and Westminster hall being excepted. In later days these courts lost much of their importance, and since defendants both in the Marshalsea and palace courts were empowered by statute to remove the cause by habeas corpus to a superior court if the damages were stated to be £5 or more, they became mainly courts for the recovery of small debts. Both the Marshalsea court and the palace court were abolished in 1849 by act of parliament.

LOREBURN, ROBERT THRESHIE REID, 1ST EARL (1846–1923), British lawyer and politician, who as lord chancellor was largely responsible for the passage of the Court of Criminal Appeal act (1907), was born at Corfu on April 3, 1846. He was educated at Cheltenham and Balliol college, Oxford, where he won the Ireland scholarship in 1868. He was called to the bar in 1871, and in 1880 entered politics as Liberal M.P. for Hereford. In 1882 he became queen's counsel and represented Dumfries Burghs from 1886 to 1905. In 1894 he became solicitor general and during 1894–95 was attorney general. On the formation of Campbell-Bannerman's government in 1905, Sir Robert Reid, who had been knighted in 1894, became lord chancellor, and was created Baron Loreburn. In 1912 he resigned on grounds of health. Lord Loreburn, who was created an earl in July 1911, published *Capture at Sea* (1913) and *How the War Came* (1919). He died at Dover on Nov. 30, 1923.

LOREE, LEONOR FRESNEL (1858–1940), U.S. railroad president, was born in Fulton City, Ill., on April 23, 1858. After graduating from Rutgers college, New Brunswick, N.J., in 1877 he entered the service of the Pennsylvania railroad as a rodman. Later railroad experience included positions with the Mexican National railway and again with the Pennsylvania. He served in engineering positions of increasing importance with the Pennsylvania and in 1901 was elected to a vice-presidency. He resigned the same year to become president of the Baltimore and Ohio railroad, and in 1904 he was chosen president of the Rock Island company. In 1907 he was elected president of the Delaware and Hudson company, a position he held for more than 30 years. He invented the upper quadrant system of semaphore signaling, built the first high-pressure locomotive and established the first or-

ganized railway police force. He wrote *Railroad Freight Transportation* (1922). He died Sept. 6, 1940, at West Orange, N.J. (W. H. D.)

LORELEI, the name of a rock with a remarkable echo in the Rhine river near Sankt Goarhausen. The word is derived from Old High German, *Lur*, connected with modern German *lauern*, "to lurk," "be on the watch for," and equivalent to *Elf* ("goblin") and *Loi* ("a rock"). In the commonest form of the story associated with it the Lorelei is a maiden who threw herself into the Rhine in despair over a faithless lover, and became a siren who lured fishermen to destruction. Clemens Brentano created the legend in its main essentials in his novel *Godwi* (1800–02). In the 19th century it formed the subject of a number of songs and dramatic sketches (listed in H. Seeliger, *Loreleysage in Dichtung und Musik*; 1898). The poem most often set to music was Heinrich Heine's "Ich weiss nicht was soll es bedeuten," of which the settings by Friedrich Silcher (from a folk song) and by Franz Liszt are the most famous.

See R. Elwenzeller-Favre, *Lorelei. Entstehung und Wandlung einer Sage* (1946).

LORENTZ, HENDRIK ANTOON (1853–1928), Dutch physicist, who shared the 1902 Nobel prize for physics with Pieter Zeeman for work on the influence of magnetism on radiation and helped lay the basis for Albert Einstein's special theory of relativity. He was born at Arnhem on July 18, 1853. He studied at Leiden, where he was appointed professor of mathematical physics in 1878. In 1912 he became director of research at the Teyler institute, Haarlem. He remained honorary professor at Leiden, where he gave a weekly lecture on modern physics, which was usually reported for publication by one of the audience.

Lorentz' work in physics was very wide in its scope, but its central aim, it appears, was to arrive at some consistent theory for electricity, magnetism and light. He tried to explain these phenomena by assuming an ether which was at rest and had electrons either at rest or moving in it. A number of phenomena were successfully explained on this electron theory, but it failed to give an explanation of the negative result of the Michelson-Morley experiment (*q.v.*). To overcome this difficulty Lorentz introduced the idea of local time in 1895. The connection between this and the Fitzgerald contraction was pointed out by Sir Joseph Larmor, and in 1904 Lorentz extended his work and arrived at the Lorentz transformation, which helps form the basis of Einstein's restricted theory of relativity (1905).

Lorentz' earlier investigations were originally published in the *Archives Néerlandaises* and consequently were not known to English physicists: Lord Rayleigh and Sir Oliver Lodge were largely responsible for the spread of his ideas in England. His first paper published in 1875, dealt with the reflection and refraction of light by dielectrics and metals. In 1880 he published a memoir on the relation between the refractive index and the density of a medium. This was the first application of James Clerk Maxwell's theory to a medium consisting of discrete molecules. Lorentz dealt with optical dispersion and tried to give an explanation on the assumption that it was due to resonant vibrations. This work was continued in his two well-known memoirs, *La Théorie électromagnétique de Maxwell et son application aux corps mouvants* (1892) and *Versuch einer Theorie der electrischen und optischen Erscheinungen in bewegten Körpern* (1895). In the latter memoir he deals with the electrodynamic field of a system moving with uniform velocity. Lorentz gave an explanation of the Zeeman effect very soon after it was observed, and predicted polarization effects which were verified later by experiment. He was also the author of a number of papers on gravitation theory, thermodynamics, radiation and kinetic theory. He was chairman of the committee of intellectual co-operation set up by the League of Nations. He died at Haarlem on Feb. 4, 1928.

Lorentz' works include *Collected Papers* (1934–39); *Lectures on Theoretical Physics* (1927–31); *Problems of Modern Physics* (1927); *The Theory of Electrons* (2nd ed. 1953).

See G. L. de Haas-Lorentz, *H. A. Lorentz* (1957). (E. Tr.; X)

LORENZETTI, the name of two brothers, both Italian painters of the Siennese school, active in the first half of the 14th

century. Their style combined the harmonious colour and expressive design of Duccio di Buoninsegna with the monumental realism of Giotto and, in the case of the elder, the dramatic naturalism of Giovanni Pisano. Their art was much imitated in Siena during the third quarter of the 14th century, and many works by close followers are still commonly attributed to one or the other.

AMBROGIO LORENZETTI (c. 1290-1348), the younger brother, ranks in importance with the greatest Sienese painters, Duccio and Simone Martini. Since neither he nor his brother is mentioned in documents after 1348, it is assumed that both died of the plague that devastated Siena in that year. Only six documented works of Ambrogio, apparently covering a period of merely 13 years, have survived. They include four scenes from the legend of St. Nicholas of Bari in the Uffizi gallery, Florence, which are parts of an altarpiece painted about 1332 in Florence; the wall decorations of 1337-39 in the Sala della Pace in the Palazzo Pubblico, Siena, representing "Good Government," "Effects of Good Government," "Bad Government" and "Effects of Bad Government"; and the signed and dated panels of the "Presentation of Christ in the Temple" (1342) in the Uffizi, and of the "Annunciation" (1344) in the Pinacoteca, Siena. Ambrogio's most important undocumented works are panel paintings of the "Madonna and Child."

It is not known who Ambrogio's teacher was, but his early works indicate that the young painter received his main inspiration from the art of Duccio, his brother Pietro and Giotto. Already at this early period his representations reveal a realistic individualism and an intense occupation with significant composition and form. These characteristics are most evident in the "Allegories" in the Palazzo Pubblico, the most important Sienese fresco decoration. In it we see Ambrogio as an acute observer of the world around him, an empirical explorer of linear and aerial perspective, a student of classical works of art, and a political and moral philosopher. His desire to depict spatial depth convincingly led Ambrogio to an increasingly accurate rendering of space in his paintings and almost to one-point perspective in his last work, the "Annunciation." With his profound interest in perspective and in classical antiquity Ambrogio anticipated the Renaissance.

PETRO LORENZETTI (c. 1280/90-1348), incorrectly called Pietro Laurati by Vasari, apparently was the elder brother of Ambrogio. His earliest certain work, the Madonna polyptych of 1320, an altarpiece in the Pieve at Arezzo, indicates that he studied under Duccio or a close pupil of this master, and that he was influenced by Giotto's solemn and Giovanni Pisano's dramatic representations. These influences are evident also in the somewhat later frescoes of the "Madonna and Child with Saints," and the "Crucifixion, Deposition, Entombment, Descent Into Limbo, and Resurrection of Christ" in the left transept of the lower church of S. Francesco, Assisi. In the Madonna painting at Arezzo and in that at Assisi the Virgin and Child are depicted intently gazing at each other, a motif directly derived from Giovanni Pisano's sculpture. In the important altarpiece of 1329 for the Carmine church, Siena, now in the Pinacoteca of that city, the artist chose a less intimate composition for the Virgin and Child, but he compensated for the formal main representation by adding very animated predella scenes, in which spatial depth is skilfully asserted.

During the 1330s Pietro became somewhat influenced by the art of his brother, with whom he produced in 1335 four scenes from the life of the Virgin (destroyed in the 18th century) on the façade of Sta. Maria della Scala, Siena. In Pietro's triptych of the "Nativity of the Virgin" in the Museo dell'Opera del Duomo, Siena (1335-42), the figures have a breadth and composure, and the space representation has an originality suggestive of Ambrogio.

(G. M. Cr.)

LORENZO, FIORENZO DI (c. 1445-c. 1525), Umbrian painter, a precursor of Pinturicchio, became a member of the guild of painters in Perugia between 1463 and 1469. In 1472 he

was elected prior of the guild and his birth is for this reason generally assumed to have taken place about 1445. A signed altarpiece in the Galleria Nazionale dell'Umbria representing SS. Peter and Paul beside a niche with a lunette of the Virgin and Child was painted in 1487. Works conjecturally datable before this time are a triptych from the Confraternità della Giustizia at Perugia and an Adoration of the Shepherds from Monteluce, both in the Perugia gallery, and a triptych in the National gallery, London. The London triptych is related to paintings by Niccolò Alunno at Deruta and by Benozzo Gozzoli at Vienna, and both these artists seem to have exercised a significant, though not necessarily direct, influence on Fiorenzo's early style. The relationship of Fiorenzo di Lorenzo's early works to paintings by Verrocchio is also noteworthy and lends some force to the view that before 1470 he worked in Florence. Documents of 1490, 1491 and 1513 relate to the production of lost works, but the artist's mature development can be traced through frescoes in S. Francesco at Deruta (1478), Monteluce (1491), Monte l'Abate (1491-92) and in the Perugia gallery (from S. Giorgio, 1498). The last reference to Fiorenzo di Lorenzo's activity dates from Feb. 1522 and he was dead by Feb. 14, 1525. After about 1480 the Verrocchiesque elements in Fiorenzo's work become less pronounced and thereafter he develops a typically Umbrian style. An attractive but relatively weak artist, Fiorenzo di Lorenzo was a precursor of Pinturicchio, who was probably a member of his studio during the 1470s. His later work is a pallid reflection of that of Pinturicchio and Perugino.

See W. Bombe, *Geschichte der Peruginer Malerei* (1912); R. van Marle, *The Development of the Italian Schools of Painting*, vol. xiv (1933). (J. W. P.-H.)

LORENZO MONACO (DON LORENZO) (c. 1370-c. 1425), Italian painter whose work combined the rhythmic, graceful flow of line and decorative feeling of the Sienese school with the Florentine traditions of the followers of Giotto. Lorenzo was born at Siena. He took the vows of the Camaldolese order in 1391 and lived mostly at the monastery of Santa Maria degli Angeli, in Florence. His name as a layman was Piero di Giovanni del Popolo di San Michele de Bisdomini and a painter of that name was entered in the books of the guild of St. Luke at Florence in 1396. Lorenzo was in some respects an innovator in Florence; in his later work he appears to be influenced by the realistic tendency of the early Renaissance. The Uffizi in Florence contains a signed work by the master, "Coronation of the Virgin" with many figures, painted in 1413 for his convent. The National gallery in London has another smaller version of the same subject; one of his most graceful altarpieces is the "Annunciation" in the Bartolini chapel in the church of Sta. Trinita at Florence. His "Madonna and Child with Angels" was acquired by the Metropolitan Museum of Art, New York city. Another late work of the master is the "Adoration of the Magi" in the Uffizi. The master's feeling for decorative composition, his expressive line and his originality come out well in his small predella pieces, as in the three small fragments at the Florence academy, representing the "Nativity," the "Life of a Hermit" and a stormy seascape, and in the two remarkable illuminations in Berlin museums of the "Journey of the Three Kings" and the "Visitation."

LORETO, episcopal see and a noted pilgrimage resort of The Marches, Italy, in Ancona province, 15 mi. S.S.E. of Ancona by rail. It lies on the right bank of the Musone. Pop. (1957 est.) 8,663 (commune).

The town, surrounded by 16th-century walls and bastions, is virtually a long narrow street, lined with shops for the sale of religious objects. The principal buildings in the Piazza della Madonna are the Palazzo Apostolico (containing works of Lorenzo Lotto and Lodovico Carracci and a replica of the tapestries designed by Raphael for the Sistine chapel) and the Basilica of the Holy House or the Santuario della Santa Casa (a late Gothic structure begun in 1468 and continued by Giuliano da Maiano, Giuliano da Sangallo, Bramante and other architects, who altered the original plan, which was again revived in 1886 by Giuseppe Sacconi). The façade of the basilica was completed under Pope Sixtus V; his colossal statue stands in the middle of the entrance steps. Over the main door is a life-size bronze statue of the Virgin and Child

by Girolamo Lombardo; the three superb late-16th-century bronze doors are also by Lombardo, his sons and his pupils. The doors of the Santa Casa (*see* below) and the magnificent chandelier over the presbytery are by the same artists. The richly decorated campanile by L. Vanvitelli is 250 ft. high, and the principal bell, presented by Leo X in 1516, weighs eight tons. The interior of the church has mosaics of Domenichino, Guido Reni, Barrocci and C. Maratti. In the old sacristies are frescoes by Melozzo da Forlì and Luca Signorelli. The Treasure room, where precious gifts and a collection of 16th-century majolica are on view, is close by.

The Santa Casa itself is of plain stone, 28 by 12½ ft., and 13½ ft. in height, with a niche containing a small black image of the Virgin and Child, in Lebanon cedar, and richly adorned with jewels. It is enclosed by a lofty marble screen, designed by Bramante, which has four sides representing the Annunciation, the Nativity, the arrival of the Santa Casa at Loreto and the Virgin's Nativity. According to tradition, the Holy House of the Virgin, threatened with destruction by the Turks, was carried from Nazareth by the ministry of angels and deposited (1291), in the first instance, on a hill at Tersatto in Dalmatia, where an alleged appearance of the Virgin and miraculous cures attested its sanctity. Three years later it was similarly transported across the Adriatic to a laurel grove (*lauretum*, whence Loreto) near Recanati and from there removed (1295) to the present hill. Papal bulls in favour of the shrine were issued. Pope Innocent XII appointed a *missa cum officio proprio* for the feast of the Translation of the Holy House (Dec. 10). Benedict XV declared the Madonna di Loreto to be the patron of aviators (1920). The chief festival is held on Sept. 8, the Nativity of Our Lady.

The Fountain of the Madonna, by C. Maderno, in the piazza, and the Fountain of the Galli (cocks) are worthy of note. The Polish War cemetery is nearby. (Po. G.)

LORETO, the largest and most easterly department of Peru, bounded north and northeast by Colombia, northwest by Ecuador, east by Brazil, west by the departments of Amazonas, San Martín, Huánuco and Junín, and south by Cuzco. Area, 184,686 sq.mi. Pop. (1961) 331,177. This area at the time that Peru gained its independence in the early 19th century was a province of the intendencia of Trujillo, under the name of Maynas. Later it became a province of La Libertad, then of Amazonas in 1853, an independent "littoral province" and finally a department. In 1906 the western portion was attached to the new department of San Martín (*q.v.*).

The chief river in the east of the department, the Ucayali, joins the Marañón or upper Amazon at Nauta. Other significant affluents of the Marañón are the Tigre, Pastaza, Morona, Huallaga and Samiria. From Iquitos westwardly ocean steamers ascend to the confluence of the Ucayali with the Marañón. The Marañón is navigable at all seasons for steamers of four- to eight-foot draft as far as Puerto Limón, a distance of 484 mi. The Huallaga is navigable at all seasons for steamers of the same draft to beyond Yurimaguas, about 150 mi. The lower Ucayali is navigable to the confluence of the Pachitea for vessels of six-foot draft.

Iquitos (pop. [1961] 55,696) is the capital of the department and entrepôt for the upper Amazon. It is served by ocean steamers and can be reached from Lima in five days via the Pucallpa highway and the Ucayali river, two days by bus and three days by river steamer.

The department, largely made up of the Amazonian plains, is almost completely forested. The climate is hot and humid with heavy rainfall (103 in., annually at Iquitos). The average elevation is about 500 ft. above sea level and the greater part of the region is inundated part of the year. Important exports of the department are rubber (the leading export before the East Indian plantations came into production), Brazil nuts, skins and hides, products of oil, medicinal and wax-bearing plants, and hardwoods. Rice, sugar cane, bananas, manioc, tobacco and other tropical products are cultivated there. The population is chiefly Indian and mestizo. (J. L. Tr.)

LORIENT, a maritime town of western France on the Bay of Biscay, in the *département* of Morbihan, is situated on the right

bank of the Scorff river at its confluence with the Blavet river. Pop. (1962) 58,504. It is important for naval construction and as a submarine base, and Kéroman to the south of the town is a thriving fishing port. The roadstead of Lorient is formed by the estuary of the Blavet and its entrance is about 3 mi. S. of Lorient. The naval port to the east of the town is formed by the channel of the Scorff, on the right bank of which the chief naval establishments are situated. A floating bridge connects the right bank with the peninsula of Caudan, which is formed by the junction of the Scorff and the Blavet. The shipbuilding yards are on this peninsula. The commercial port consists of a quay in deep water. Kéroman's port facilities include two tidal docks accessible to fishing boats at all times, a covered auction market, fishmongers' warehouses, an ice works and a slipway for the renovation and repair of trawlers. Employment is provided by the naval arsenal, the fishing and commercial ports, and factories that can sardines and tunnies. The town's principal imports are exotic and northern woods, coal, Algerian wine and hydrocarbons. It exports kaolin, kale, fish, oysters and tin plate. (G. Man.)

History.—At the entry to the roadstead of Lorient, which is well protected by the isles of Groix and Belle-Isle, a small hamlet named Blavet grew up in the late middle ages. A citadel was built there under Louis XIII and Blavet was renamed Port Louis. Companies of merchants established themselves there, and in 1664 Louis XIV sanctioned the creation of a new and more important *Compagnie des Indes*, which settled at the mouth of the Scorff. The company prospered and from its commercial and colonial expansion in the orient came the name "L'Orient" in 1666. France's war against the Grand Alliance was fatal to the company and the town. New life was given to Lorient in 1719 when John Law, the Scottish banker, formed a new company. In 1732 Lorient became the marketing centre of the company, and its annual fair was the most important in Europe. In 1738 it was made a free town. By the middle of the 18th century its prosperity made it the rival of London and Amsterdam. But the disasters of the Seven Years' War and the ruin of the company were serious blows to the city's progress. In 1770 the property of the company was ceded to the state, and in 1782 the king established a royal arsenal at Lorient. The French Revolution brought ruin to the city's trade, but its arsenal was later modernized and continued into the 20th century to be a major element in the economic life of the city. The town was virtually destroyed by Allied bombing during World War II because it was used by the Germans as a submarine base, but it was later rebuilt along modern lines. (G. Gx.)

LORIMER, GEORGE HORACE (1867–1937), U.S. editor, long associated with the *Saturday Evening Post*, was born at Louisville, Ky., Oct. 6, 1867. He attended Colby college and Yale university and, after a short time in business in Chicago, became a newspaper reporter and correspondent. In 1897 he was literary editor of the *Saturday Evening Post* and in 1899 became its editor in chief. The remarkable success of this periodical was largely caused by Lorimer's keen appreciation of the public taste, coupled with his ability to meet it. His *Letters From a Self-Made Merchant to His Son* (1902), which attained great popularity, and *Old Gorgon Graham* (1904) are effective expositions of the philosophy of getting on. He continued his editorship of the *Post* until Jan. 1, 1937, and died at Wyncote, Pa., Oct. 22, 1937.

See John Tebbel, *George Horace Lorimer and The Saturday Evening Post* (1948).

LORIMER, JAMES (1818–1890), Scottish jurist and authority on international law, was born at Aberdalgie, Perthshire, on Nov. 4, 1818, and was educated at Edinburgh university. After study abroad he was admitted to the Scottish bar and in 1866 became professor of public law in Edinburgh university, where he taught until his death on Feb. 13, 1890. Against the positivism of contemporary English jurisprudence Lorimer taught a doctrine of natural law founded on divine authority and revealed in cosmology and in history; in particular he held that the science of international law should be concerned with the application of this natural law to the relations of nations with one another. Lorimer's system did not prove of permanent value but his writings are

memorable for their vigour and for flashes of prophetic insight, notably his draft scheme (1870) for a "permanent congress of nations" and an international court of justice.

His major writings are: *The Institutes of Law* (1872); *The Institutes of the Law of Nations*, 2 vol. (1883-84); *Studies National and International* (1890).

LORIS, the common name for Indo-Malay lemurs (see *PRIMATEs*). Their soft fur, huge staring eyes, rudimentary tails and imperfectly developed index fingers render lorises easy of recognition. The slender loris (*Loris tardigradus*), of the forests of Madras and Ceylon, is smaller than a squirrel. The slow loris (*Nycticebus coucang*) is a heavier built and larger animal, known for its deliberate and unhurried pace. It ranges from eastern Bengal to Indochina, the Malay peninsula, Java, Borneo and Mindanao.

W. SUSCHITZKY
SLOW LORIS (*NYCTICEBUS COUCANG*), FOUND IN SOUTHEASTERN ASIA

LORIS-MELIKOV, MIKHAIL TARIELOVICH, COUNT (1826-1888), Russian army officer whose military successes were followed by a brief career of enlightened statesmanship, was born at Tiflis on Jan. 1, 1826, the son of an Armenian merchant. Educated in St. Petersburg at the Lazarev school of oriental languages and at the Guards' cadet institute, he joined a hussar regiment in 1843. In 1847 he was sent to the Caucasus, where he spent 20 years. He was governor of the Terek area from 1863 to 1875. In the Russo-Turkish War of 1877-78, commanding an army corps, he took the fortress of Ardahan, was repulsed by Mukhtar Pasha at Zevin, but then won a victory at Aladja Dag, took Kars by storm and laid siege to Erzurum. For these services he received the title of count.

In 1879 Loris-Melikov was appointed temporary governor-general of the region of the lower Volga, to combat an outbreak of the plague. He was then transferred to the provinces of central Russia to combat revolutionary terrorism. He advocated removing the causes of popular discontent, and for this purpose he recommended to the emperor a modest scheme of administrative and economic reforms. The emperor, Alexander II, thereupon in Nov. 1880 appointed Loris-Melikov minister of the interior with exceptional powers. The proposed scheme of reforms was never carried out. On the very day that he signed an *ukaz* creating the necessary commissions, Alexander was assassinated (March 13, 1881); and his successor, Alexander III, adopted a reactionary policy. Loris-Melikov resigned on May 19, 1881, and lived in retirement until his death at Nice, France, on Dec. 24, 1888.

LORME, MARION DE (1613-1650), the celebrated French courtesan whom Victor Hugo made the heroine of a drama and who figures also in Alfred de Vigny's novel *Cinq-Mars*, was born in Paris on Oct. 3, 1613, the daughter of Jean de Lon, sieur de Lorme, and Marie Chastelain, and was brought up at the château of Baye, near Champaubert. She was introduced to the life of pleasure by Jacques Vallée, sieur des Barreaux, a *libertin* or free-thinker, who expressed his sincere love for her in passionate verse. She soon left him, however, for the marquis de Cinq-Mars (*q.v.*). Louis XIII's elegant young favourite, whom at one moment she was on the point of marrying. She then set herself up in the fashionable Place Royale (now the Place des Vosges) in Paris, where her salon attracted the most brilliant company of the town. After the execution of Cinq-Mars (1642), she had many lovers: Saint-Evremond; the marquis de Rouville (Hercule Louis); the soldier and poet Isaac Arnauld de Corbeville; the comte de Miossens (César Phébus, later marshal d'Albret); the comte de Coligny (Gaspard de Chatillon), who was converted to Catholicism to please her; the duc d'Enghien (Louis de Bourbon Condé); the duc de Brissac (Louis de Cossé); the comte de Gramont (Philibert); the superintendent of the finances, Michel Particelli d'Emery; and even the cardinal de Richelieu himself. Paul Scarron and other poets were among her friends and wrote in praise of her. The

marshal de La Meilleraye (Charles de La Porte), Emery's successor as superintendent during the Fronde, began a persecution of her, and she had to leave the Place Royale and go to her mother's house in the rue de Thorigny. Though most of her friends and lovers supported the opposition to Cardinal Mazarin, there is no proof of the story that she was about to be arrested when she died, in poverty, on July 2, 1650. Her body, in a white dress, was laid out as if in state, and the curé of the parish of St. Paul had to intervene to stop this scandal. The 18th-century story that she died a centenarian is without foundation.

See J. Péladan, *Histoire et légende de Marion de Lorme*, 2nd ed. (1927); G. Mongrédien, *Marion de Lorme et ses amours* (1940). (G. Mo.)

LÖRRACH, a town in the extreme southwestern part of Germany which after partition of the nation following World War II became part of the *Land* (state) of Baden-Württemberg, Federal Republic of Germany, is situated on the Wiese, 9 km. (5½ mi.) N.E. of Basel, Switz., by road. Pop. (1961) 30,536. The position of Lörrach, where the Wiese leaves the mountains, is agreeable. The castle of Markgrafenburg and the ruins of that of Rötteln are nearby. From Tüllinger Höhe there is a view of three countries, and by night the lights of Basel can be seen. Lörrach is connected with Basel by railway and (1960s) by trams (streetcars). There are a considerable textile industry and some light manufactures. There are extensive vineyards and also trade in wine, fruit and timber. Lörrach is a centre for the transmission of the electric power generated from the Rhine nearby. It received market rights in 1403 and municipal privileges in 1682.

LORRAIN, CLAUDE; see *CLAUDE LORRAIN*.

LORRAINE, CHARLES DE LORRAINE, CARDINAL DE (1525-1574), one of the foremost members of the house of Guise (*q.v.*) in French politics of the third quarter of the 16th century, was born at Joinville on Feb. 17, 1525, the second son of Claude, 1st duc de Guise, and Antoinette de Bourbon. He was from the first destined for the church, and studied theology at the Collège de Navarre in Paris. He attracted Francis I's notice by his oratorical gifts and in 1538 became archbishop of Reims. Soon after Henry II's accession, he received the red hat (1547); he was called cardinal de Guise until 1550, when his uncle, Jean, died and he took over his title of cardinal de Lorraine as well as his numerous benefices, which included the see of Metz and the abbeys of Cluny and Fécamp. Charles' income amounted to 300,000 *livres* annually and his ecclesiastical patronage was extensive. The cardinal was also very important politically: as a member of the king's council he actively supported the policy of French intervention in Italy; and in 1559 he helped to negotiate the peace of Câteau-Cambrésis. Although he was a grand inquisitor and did persecute Huguenots, Charles was by nature inclined to piancy and leniency. Under Francis II, he and his brother François, 2nd duc de Guise, gained control of the government; their unpopularity provoked the conspiracy of Amboise. On the accession of Charles IX (1560), he became less influential in state affairs, but the regent, Catherine de Médicis, listened to his religious advice. In 1561 he defended the Catholic viewpoint against Theodore Beza at the colloquy of Poissy. In 1562-63 he championed the Gallican cause at the Council of Trent, but in 1564 he tried, unsuccessfully, to secure the promulgation of the council's decrees in France. After continuing to serve Catherine for a while, he retired from court in 1570. Charles de Lorraine combined a handsome physique with intellectual gifts, but he was avaricious and cowardly, and his versatility often made him appear hypocritical and ineffective. He died at Avignon on Dec. 26, 1574.

(1913-14), *La Conjuraison d'Amboise* (1923), *Catholiques et Huguenots à la cour de Charles IX* (1924); H. O. Evennett, *The Cardinal of Lorraine and the Council of Trent* (1930). (R. J. K.)

LORRAINE (Ger. *LOTHRINGEN*), the name given first, in original form *LOTHARINGIA*, to a kingdom intermediate between the Western and Eastern kingdoms of the Carolingian empire; then to the two duchies into which Lotharingia was divided, Lower Lorraine and Upper Lorraine; then to a duchy based on Upper

Lorraine alone. Annexed to France in the 18th century, this last Lorraine was divided in 1790 among four *départements*, Meuse, Meurthe, Moselle and Vosges, corresponding to the later Meuse, Meurthe-et-Moselle, Moselle and Vosges (*q.v.*). Geographically, Lorraine is the area bounded north by the Ardennes region and by the Hunsrück massif; east by the Vosges mountains; south by the Monts Faucilles and by the Langres plateau; and west by the Argonne plateau. The upper courses of the Meuse and Moselle rivers, separated by the Woëvre plateau, traverse the western part of Lorraine, the Sarre river the eastern. The soil contains the greatest iron-ore deposits in Europe.

Lotharingia.—By the treaty of Verdun (A.D. 843), the three sons of the Carolingian emperor Louis I the Pious divided the Frankish territory into three parts: Francia Occidentalis went to Charles II the Bald, Francia Orientalis to Louis the German, and Francia Media, the zone extending from the Low Countries to Italy, to the emperor Lothair I. This Francia Media was partitioned by Lothair I in 855 between his sons: the elder, Louis II, received Italy and the imperial title; the younger, Lothair (*q.v.*), received the northern area thenceforward known as Lothair's kingdom or Lotharingia.

This kingdom was bounded north by the North sea; east by a line from the mouth of the Ems river to Wesel and then by the Rhine southward to the confluence of the Aar (but with a westward recession of the frontier that left Mainz, Worms and Speyer to the Germans); south by the Aar and by the Jura mountains; and west by the Saône (from a point just south of the Doubs confluence), the Ornaïn, the Meuse and the Scheldt. Lotharingia thus comprised the dioceses of Utrecht, Cologne, Trier, Strasbourg, Basel, Besançon, Toul, Metz, Verdun, Cambrai and Liège.

When King Lothair died without heirs in 869, Charles the Bald and Louis the German dismembered Lotharingia: by the treaty of Mersen (Meerssen) in 870 Charles received Liège, Verdun, Toul and Besançon, while Frisia and the eastern territory went to Louis. By the treaties of Verdun and Ribémont, however, in 879–880, the West Frankish kings Louis III and Carloman ceded their part of Lotharingia to Louis the Younger, king of the East Franks or Germans. When the latter's brother, the emperor Charles III the Fat, was deposed (887), Rudolf I of Burgundy annexed Besançon to his own kingdom; but the main part of Lotharingia remained with the East Franks, whose king Arnulf gave it as a kingdom to his bastard Zwentibold in 895. When Zwentibold was killed in battle on the Meuse (Aug. 13, 900), his half brother, the East Frankish king Louis the Child, succeeded him in Lotharingia; but in 911 the Lotharingians refused to accept the German king Conrad I, of the new Franconian dynasty, as their ruler and acknowledged instead the West Frankish Carolingian, Charles III the Simple.

At this time one of the most powerful counts in Lotharingia was Rainier or Reginar I of Hainaut. His son Gisbert wanted to make himself king of Lotharingia and took part in the revolts that led to the deposition of Charles the Simple. Gisbert, however, could not maintain himself against France without help from the German king Henry I, who after a first campaign in 923 recovered Lotharingia for Germany in 925. Married to Henry's daughter Gerberga, Gisbert was duke of Lotharingia by 928.

Gisbert rebelled against Henry's successor Otto I but was defeated near Andernach and drowned in the Rhine (Oct. 2, 939). Otto I then invested a certain Count Otto, son of Ricuin, with the duchy of Lotharingia and, in 942, obtained recognition of his suzerainty over it from the French king Louis IV d'Outremer, who had supported Gisbert's rebellion and had married Gisbert's widow. When Otto, son of Ricuin, died (944), Otto I gave the duchy to his own son-in-law, Conrad the Red. Having deposed Conrad for rebellion in 953, Otto entrusted the administration of the duchy to his brother Bruno, archbishop of Cologne (d. 965).

Upper Lorraine and Lower Lorraine.—In 959 Bruno divided Lotharingia into two parts, Upper Lorraine the southern and Lower Lorraine the northern, with their boundary running from a point on the Rhine north of Andernach westward and southward to a point on the Meuse north of Mézières. Lower Lorraine thus included most of the historic Netherlands belong-

ing to the German kingdom between the Rhine, middle Meuse and Scheldt rivers, while Upper Lorraine included the Ardennes, the Moselle valley and the upper Meuse valley. At least from Bruno's death, Upper Lorraine was held as a duchy by Frederick (d. 978 or 984), count of Bar, a descendant of the Carolingians through his mother and Bruno's nephew by marriage, who was succeeded as duke in turn by his son Dietrich (d. 1026) and by the latter's son Frederick II (d. 1033). Lower Lorraine was entrusted first, as a march or marquisate, to a certain Godfrey (d. 964); but in 977 the emperor Otto II invested the Carolingian prince Charles (*q.v.*) as duke of Lower Lorraine. Charles was succeeded by his son Otto, but after the latter's death Lower Lorraine was given in 1012 to a count of the house of Ardenne, who became duke as Godfrey I (d. 1023). Godfrey I was succeeded by his brother Gozelo or Gothelo I, who in 1033 obtained Upper Lorraine also.

On Gozelo I's death (1044) Lotharingia was divided again between two of his sons: Godfrey the Bearded (d. 1069) received Upper Lorraine, Gozelo II (d. 1046) received Lower Lorraine. Godfrey the Bearded, angry at the division, became a persistent rebel against his suzerain, the emperor Henry III. Finally deprived of Upper Lorraine he went to Italy and, in 1054, married Beatrice, mother of the great heiress Matilda of Tuscany. Reconciled at last with the German kingship, Godfrey the Bearded was invested with Lower Lorraine in 1065, on the death of Frederick of Luxembourg (Gozelo II's successor). Upper Lorraine meanwhile had been granted in 1047 to a certain Adalbert (d. 1048) of the house of the counts of Metz, and then to his nephew Gerard of Châtenois.

The duchy of Lower Lorraine passed in 1070 to Godfrey the Bearded's son, Godfrey III the Hunchback, on whose assassination in 1076 the German king Henry IV bestowed it on his own two-year-old son Conrad. In 1087, however, the ducal title was transferred to Godfrey (*q.v.*) of Bouillon, the Hunchback's nephew. After Godfrey's death on the first crusade (1100), Henry IV gave the duchy in 1101 to Henry I, count of Limburg (d. 1119?). By this time, however, ducal authority had already been weakened by the rise of other countships in the area besides Limburg, such as Hainaut, Louvain and Namur, and by the consolidation of the bishopric of Liège; and the troubles of the German kingdom led to further disorders. The German king Henry V in 1106 replaced Henry I of Limburg as duke by the count of Louvain, another Godfrey also called the Bearded; then Lothar II, Henry V's successor, in 1128 replaced Godfrey the Bearded in turn by Henry's son Walram II of Limburg. In 1139 both Godfrey the Bearded and Walram II died, and the Hohenstaufen German king Conrad III finally gave the ducal title to Godfrey's son Godfrey II of Louvain (d. 1142), with whose descendants, styled dukes of Lothier, it remained, though the house of Limburg contested it at least till 1155. Eventually the counts of Limburg became dukes of Limburg instead; and in 1190 Godfrey II's grandson dropped the title duke of Lothier and took that of duke of Brabant, as Henry I (d. 1235). (See BRABANT, DUCHY OF; LIMBURG, DUCHY OF.)

The Duchy of Lorraine.—With the dissolution of the Lower duchy, the Upper duchy alone conserved the name Lorraine. It remained with the male descendants of Gerard of Châtenois till 1431. The succession—from father to son unless otherwise indicated—was as follows: Gerard (d. 1070); Thierry (d. 1115); Simon I (d. 1139); Matthew (d. 1176); Simon II (till 1205; d. 1207); Ferry or Frederick I (Simon's brother; 1205–06; d. 1207); Ferry II (d. 1213); Thibaut or Theobald I (d. 1220); Matthew II (Thibaut's brother; d. 1251); Ferry III (d. 1303); Thibaut II (d. 1312); Ferry IV (d. 1328); Rudolph or Raoul (d. 1340); John I (d. 1391); and Charles II (d. 1431).

The authority of these dukes was offset not only by the temporal power of the three bishoprics within their frontiers, namely Metz, Toul and Verdun, but also by the rise of great feudal dynasties; the counts of Luxembourg challenged the dukes in the north; the counts of Bar (*q.v.*), heirs to the patrimony of Frederick II of Upper Lorraine from 1033, were dangerous vassals in the west; and from 1070 a junior branch of the ducal house held the county of Vaudémont in the southwest. The dukes therefore, who

had their capital at Nancy (*q.v.*) from the middle of the 12th century, were reluctant to forfeit the protection of their suzerains, the German kings. In the Investiture conflict of the 11th–12th century they took the royal or imperial side, together with the bishops of Verdun, while Bar and Metz took the papal; and in the dispute for the German kingship after 1198 they supported the Hohenstaufen candidate till 1213, when Thibaut I changed to the Welf side (Bar thereupon made the converse change). After his victory in 1215 the Hohenstaufen king Frederick II intervened effectively in Lorraine, but from 1250 his successors were too weak to protect the area from French encroachment.

Louis IX of France mediated between Luxembourg and Bar in a territorial quarrel (1268); Philip IV of France took Toul under his protection (the cathedral chapter in 1289, the town in 1300) and received homage from Bar for lands west of the Meuse (1301); and Louis X obtained a protectorate over Verdun (1315), which however became ineffective in the early part of the Hundred Years' War. Having at first resented the French approach, the dukes, who were more interested in Metz than in the other bishoprics, for a time became open partisans of France (Raoul was killed fighting the English at Crécy). The German king Charles IV, himself a member of the house of Luxembourg and well-disposed toward France, was only concerned with stabilizing the area: Luxembourg and Bar were both erected into duchies, on a par with Lorraine, in 1354.

In the 15th century ducal policy was conditioned by Lorraine's position between the northern and southern halves of the great new Burgundian state (*see* BURGUNDY; FRANCHE-COMTÉ; NETHERLANDS, THE: *History*). Charles II (*q.v.*) of Lorraine long collaborated with Burgundy against France, but modified his attitude when his heiress Isabella was married in 1420 to René of Anjou (*see* RENÉ I), brother-in-law of the future king of France, Charles VII.

René became duke of Bar in 1430; but on Charles II's death in 1431, Antony of Vaudémont, son of Charles II's younger brother Ferry (d. 1415) by the heiress of Vaudémont, contested René's claim to succeed to Lorraine by right of Isabella. René was taken prisoner at Bulgnéville (July 1431) and released only in 1436 at the price of great concessions to Antony's Burgundian ally, who moreover proceeded to acquire Luxembourg in 1443. To counteract this Burgundian aggrandisement Charles VII of France led an expedition into Lorraine, reasserted the protectorate over Toul and Verdun and besieged Metz (1444–45). René had to resign Lorraine to his son John on Isabella's death (1453). John was succeeded by his son Nicolas I (1470), and Nicolas by his aunt Yolande's son René II (1473), who already in 1472 had succeeded his father Ferry (Antony's son) in Vaudémont.

Charles the Bold, duke of Burgundy, invaded Lorraine in 1475 and took Nancy, but his death in battle outside Nancy in Jan. 1477 saved René II's duchy. On the death of René I, who had retained Bar, René II succeeded him in that duchy (1480), thus reuniting it at last with Lorraine and Vaudémont. This consolidation, together with the ducal house's success in installing its members in the bishoprics, enabled Lorraine to confront the new situation caused by the passing of the Burgundian inheritance to the Habsburgs. The Habsburgs as Holy Roman emperors might have liked to strengthen Lorraine's theoretical attachment to the *Reich*, but they were soon preoccupied with the troubles of the Reformation in Germany; and France's struggle against the Habsburgs gave René II (d. 1508) and his son and successor Antony the opportunity to build Lorraine up as a neutral buffer state. By the treaty of Nürnberg (Aug. 26, 1542), the emperor Charles V recognized the duke's sovereign freedom from feudal obligation for all his territory save a few little fiefs, at the same time undertaking that the *Reich* would protect Lorraine.

Antony's death and the accession of his son Francis I (June 14, 1544) coincided with the crossing of Lorraine by an imperial army on its way to invade French Champagne. Within a year Francis was dead (June 12, 1545), leaving Lorraine and Bar to the two-year-old Charles III (*q.v.*). Henry II of France, having seen the frontier's weakness, concluded the treaty of Chambord (1552) with a number of German Protestant princes who, in return for

support in their rebellion, consented to his occupying Metz, Toul and Verdun as vicar of the *Reich*. The French occupied the three bishoprics, and François de Lorraine, duc de Guise (Charles III's cousin; *see* GUISE [HOUSE OF]) held Metz heroically against siege by the emperor. Charles III was taken to the French court.

After the peace of Câteau-Cambrésis between France and Habsburg Spain (1559), Charles III returned to his duchies, which he raised to the zenith of their prosperity. While France, torn by the civil wars of religion, could not thrust the spearhead of occupation any further into Lorraine, Charles confirmed his links with Germany by acquiring places in the Saarland, developed the administration and economy and pushed the Counter-Reformation forward (University of Pont-à-Mousson, founded in 1572 and given over to the Jesuits). In 1584 he adhered openly to the Holy League sponsored by his Guise cousins in France, but by 1594 hostilities between him and the French king Henry IV were over.

Charles III's son Henry II, duke from 1608, did homage for Nomény to the emperor Matthias in 1613. For the strange transactions following Henry's death (1624) and the reigns of the duchess Nicole (1624–25) and of the dukes Francis II (1625), Charles IV (1625–34, 1641–44 and 1661–70) and Nicolas Francis (nominally and momentarily duke, 1634), with the chronology of the successive French occupations of Lorraine between 1633 and 1670, *see* CHARLES IV. Metz (where the French set up a *parlement* in 1633), Toul and Verdun were formally renounced to France by Germany under the peace of Westphalia in 1648. They were then organized as the *généralité* of Metz, under an intendant. The dispossessed Charles V, titular duke from 1675, rejected the terms procured by the emperor Leopold I for the restoration of Lorraine to him under the treaty of Nijmegen (1679), which required *inter alia* the surrender of Nancy to France in exchange for Toul. Subsequently Louis XIV of France set up a chamber in the *parlement* of Metz to arrange the "reunion" to France of further areas supposed to have been feudally dependent on the bishoprics. Only after the War of the Grand Alliance were Lorraine and Bar restored to Charles V's son Leopold, under the peace of Rijswijk (1697), with conditions, however, that kept him defenseless against France.

Leopold undertook the rehabilitation of his country. He codified the law, promoted glass, paper and textile industries as well as ironworking and attracted thousands of immigrants; but he had to submit to another French occupation (1702–14) during the War of the Spanish Succession. On his death in 1729 the duchies passed to his son Francis Stephen (Francis III of Lorraine; *see* FRANCIS I, Holy Roman emperor), whose betrothal to Maria Theresa, the emperor Charles VI's heiress, made a change of dynasty inevitable, since France could never admit the union of Lorraine and the Habsburg lands. In the War of the Polish Succession, therefore, under the peace preliminaries of Vienna (1735), it was agreed that Francis Stephen should eventually succeed to Tuscany and should meanwhile renounce Lorraine and Bar, which were to go to the dispossessed Polish king Stanislaw I (Stanislaw Leszczynski) and then to the latter's daughter Marie, already the consort of Louis XV of France. Stanislaw took possession of Lorraine in 1737, and the preliminaries were confirmed by the definitive peace of Vienna in 1738.

Maintaining a gay little court at Lunéville and indulging his taste for architecture (Nancy is his great monument), Stanislaw left the government of Lorraine to his chancellor, A. M. Chaumont de La Galaizière, who paved the way for Lorraine's incorporation into France. On Stanislaw's death (1766) Lorraine and Bar became French. A *généralité* was set up at Nancy. The *parlement* of Nancy was created in 1776.

Lorraine was dissolved into *départements* in 1790, during the French Revolution. For the later annexations of part of the old Lorraine to the German *Reich*, *see* ALSACE-LORRAINE. For Lorraine as a great industrial region *see* FRANCE: *The Economy*. *See* also references under "Lorraine" in the Index.

LORRY: see MOTOR TRANSPORTATION.

LORTZING, (GUSTAV) ALBERT (1801-1851), German composer of light romantic operas. Born at Berlin on Oct. 23, 1801, he was largely self-taught. His first opera, the one-act vaudeville entitled *Ali Pascha von Janina*, was produced in 1828. He produced several other light works of this kind including a play with songs, *Der Pole und sein Kind* (1832), and *Szenen aus Mozarts Leben*, a play with music selected from Mozart's works, written in 1832 but not produced. From 1833 to 1844 he was employed as a tenor at Leipzig, where his *Die beiden Schützen* (1837) was well received. His most successful opera, *Zar* (originally *Czaar*) und *Zimmermann*, based on an episode in the life of Peter the Great, was given at Leipzig in 1837 and in Berlin two years later. Between 1840 and 1850 he produced nine operas, chiefly at Leipzig, on librettos devised by himself and based on French and German plays. Among them were *Undine* (1845), a romantic opera in the style of Weber and Marschner, and *Rolands Knappen* (1849), a lighter work in the comic style. During this period he was also well known as a conductor and wrote incidental music. He died at Berlin on Jan. 21, 1851.

Lortzing's style derives from that of the early 19th-century French *opéra-comique*, which enjoyed a great vogue in Germany during the composer's lifetime, and also from the German *Singspiel*. The style of light German opera that he established remained in favour until the middle of the 20th century.

LORY: see PARROT.

LOS ALAMOS (Spanish meaning "the cottonwoods"), a town of New Mexico, U.S., and seat of Los Alamos county, lies 24 air mi. N.W. of Santa Fe, at an elevation of 7,300 ft., on the summit of one of the innumerable mesas comprising the Pajarito plateau, a forested shelf on the eastern slope of the Jemez mountains.

Until 1942 the site was occupied solely by a group of log cabins and stone buildings comprising the Los Alamos Ranch School for Boys. The mesa was selected because of its comparative isolation and natural facilities as the site for the atomic research laboratory then known as the Manhattan project or Project Y which developed the first nuclear-fission or A-bomb. (See *ATOMIC ENERGY: The Atomic Bomb*.) After World War II, the Los Alamos Scientific laboratory, operated by the University of California for the Atomic Energy commission, developed the first thermonuclear-fusion or H-bomb. The town's sole reason for existence is the Scientific laboratory, which is one of the greatest atomic research institutions in the world. The laboratory has been expanded to neighbouring South Mesa where it utilizes about 300 buildings and 77 sq.mi. Research includes basic scientific development directed toward industrial uses of atomic energy, health, radiology, organic chemistry and industrial hygiene.

By the 1960s the small complex of makeshift residential quarters for scientists had grown into the modern town of Los Alamos. (For comparative population figures see table in *NEW MEXICO: Population*.) In 1949 it was named the seat of Los Alamos county, the state's newest and smallest county (area 108 sq.mi.), created from part of Sandoval county. In Feb. 1957 it was made an "open city" which anyone could visit, although only persons who are employed there can take up permanent residence. The commission-manager form of municipal government was adopted in 1955.

The Banderier National park is 5 mi. S., and the Puye pre-Columbian ruins are a few miles north of the town. (Fr. W.)

LOS ANGELES, a vast, sprawling metropolis, seat of Los Angeles county, located in southern California, U.S., was until 1961 the largest city in area (455 sq.mi. in 1960). It is about 350 mi. S.E. of San Francisco and 110 mi. N.N.W. of San Diego. It has an average altitude of about 275 ft., ranging from sea level to 1,652 ft. atop Mt. Hollywood. The geographical setting between the mountains and the sea is attractive; the central commercial district lies several miles from the Pacific ocean on a coastal shelf extending inland to the foothills of the San Gabriel mountain range.

The original Spanish town or pueblo, located close to a series of man-made water ditches or *zanjas* that drained water from these

mountains, was built around a square, which is the historic plaza area of the modern city. Urban growth was to the south, east and west from this original nucleus, especially after the coming of the railroads in the 1870s. Separate municipalities, by the 1880s, sprang up nearby, of which Pasadena (*q.v.*) is the largest; others whose interests are closely bound with Los Angeles include Alhambra, Burbank, Culver City, Glendale, Huntington Park, Inglewood, Long Beach, Santa Ana, Santa Monica, South Gate, Torrance (*qq.v.*) and Compton. A sizable spur of foothills toward the west, which for a time blocked expansion in that direction, was eventually pierced by tunnels and boulevards. The problem of access to the sea was solved by annexation of a strip of land, about 20 mi. long, and $\frac{1}{4}$ mi. wide, known as the "shoestring strip." This corridor connects the metropolis with Los Angeles harbour. The city touches the ocean at the annexed towns of San Pedro, Wilmington and Venice, and entirely surrounds such separate municipalities as Beverly Hills (*q.v.*), Vernon and San Fernando. There are about 45 relatively large municipalities within Los Angeles county (area 4,060 sq.mi.). Among them is Hollywood (*q.v.*), 8 mi. N.W. of the business district which by annexation is municipally a part of Los Angeles, but retains its name and business entity. A city ordinance, repealed in 1957, that limited the height of buildings to 150 ft., encouraged the decentralization of Los Angeles.

Climate.—Little variability is the chief characteristic of the climate at Los Angeles and in southern California generally. Winter is a season of moderate rainfall, 15.23 in. yearly being the average. There is relatively little rain from May to October. Winter days are sunny and warm and the nights are often cold, with occasional frost in December and January. A 50-year average of the records of the U.S. weather bureau shows the mean temperature to be 62.4°. There is a 72% possibility of daily sunshine, an average of 179 clear days each year, and only 37 days with more than .01 in. of rain. However, serious floods have occurred, notably in 1914 and in 1938; the greatest disaster was in 1928 when the St. Francis dam unit of the Los Angeles aqueduct collapsed resulting in violent floods of the Santa Clara river through Los Angeles and Ventura counties. Los Angeles experienced a moderate earth tremor about once every five years during the first half of the 20th century. The earliest recorded earthquake occurred in 1769 when the expedition led by Gaspar de Portolá (see *History*, below) reached the banks of the Santa Ana river, which was appropriately named *El Río del dulce nombre de Jesús de los temblores* ("the river of the sweet name of Jesus of the earthquakes").

The average wind velocity of only 6.1 mi. per hour, one of the lowest of any major U.S. city, has directly contributed to one of Los Angeles' most pressing modern problems, heavy air pollution leading to smog. Pollution of the atmosphere by choking noxious fumes causes uncomfortable eye irritation and has led to the establishment of an air pollution control district, operated by the Los Angeles county board of supervisors. This agency has conducted studies which traced smog to three main sources: automobile exhausts, industry and home incinerators. In 1956-57 local regulations forbade the burning of trash, and home incineration was replaced by the city's first thorough municipal rubbish collection system. Surveillance of industrial air pollution failed to reduce the climatic discomfort of Los Angeles. Two warning systems (one anticipatory, the other remedial) had to be instituted for the protection of health by averting hazardous concentrations of contamination. Eye irritation is especially severe in the summer months.

Population Characteristics.—In the past, the relationship of good climate to spectacular growth marked the development of Los Angeles. Sunny skies and the attractions of outdoor life caused population within the city limits to soar from 576,673 in 1920 to 1,238,048 in 1930. Further increase in the 1930s occurred partially because of the immigration of job hunters from depressed areas, retired persons and Hollywood aspirants. According to the census bureau, the city's population grew from 1,504,277 in 1940 to 1,970,358 in 1950. By 1960 it ranked as the third largest city in the U.S. The population booms of the 1880s and 1920s were eclipsed during and after World War II when expansion was

SCENES IN LOS ANGELES COUNTY

accelerated by an influx of workers for defense industries. The 1960 city population was 2,479,015. The Los Angeles-Long Beach standard metropolitan statistical area (Los Angeles and Orange counties) had a population of 6,742,696 in 1960. In 1963 the standard metropolitan statistical area was redefined as comprising Los Angeles county only, 1960 population 6,038,771, and Orange county was designated a separate standard metropolitan statistical area (Anaheim-Santa Ana-Garden Grove). Demographers forecast a population of 10,500,000 persons for the Los Angeles metropolitan area by 1975, when the city should (if annual population growth of about 240,000 should continue) become the largest in the U.S. The population, aside from groups that characterize other large U.S. cities, includes considerable numbers of Mexicans, Chinese, Japanese and Filipinos. (For comparative population figures see table in CALIFORNIA: Population.)

History.—On Aug. 1, 1769, a Spanish exploring expedition under Gaspar de Portolá (*q.v.*) and Father Juan Crespi, traveling northward from the peninsula of Lower California through San Diego, reached an Indian village called Yang-na near a stream, at the present site of Los Angeles. They named the place Our Lady Queen of the Angels (*Nuestra Señora la Reina de Los Angeles*). The Indian settlement remained relatively undisturbed for 12 more years. Then, on Aug. 18, 1781, as part of Spain's design to colonize California more thoroughly, the future city's first permanent residents arrived after a 100-day march northward from Mexico through the blistering heat of the deserts. These humble, mostly illiterate folk consisted of 12 families (46 persons in all), of mestizo (Spanish-Indian), Negro and Spanish blood. On Sept. 4, 1781, California's Spanish governor, Felipe de Neve, gave the community of Los Angeles official status as the territory's second (after San Jose, founded in 1777) pueblo.

The nearby Franciscan mission of San Gabriel—still in existence as an intact landmark—had been established ten years earlier a few miles from the centre of the new pueblo. Development of a better overland route from Sonora and Sinaloa to California (opened as early as 1775 by Juan Bautista de Anza) markedly increased the number of travelers that had come over the Lower California route. The new arrivals cleared the wild mustard and sagebrush and settled upon land grants given them by Spain's authority. They thereby began the great southern California ranchos of the future, some of which were to be larger than whole European countries.

After Mexico's independence from Spain (1822) frequent political disturbances and revolts hampered the social and economic stability of the little town. The few Americans who visited it during this period included the fur trapper Jedediah Strong Smith, the first white man to come overland, in 1826, via San Gabriel mission, from the Missouri river frontier settlements. In search of beaver and otter, Smith preceded the first organized overland pioneers (the William Workman-John Rowland party of 1841) into Los Angeles by 15 years. During the 1830s, however, other American fur trappers such as James Ohio Pattie and Ewing Young reached Los Angeles, pioneering the future western routes of the covered-wagon migrants.

In 1835 the Mexican congress declared Los Angeles the capital of California, an edict that was hardly enforced by governors who favoured the north. For a time, just prior to the U.S. conquest of 1846, Gov. Pio Pico, California's last Mexican governor, removed the capital to Los Angeles. The city was rent by north-south and local factional quarrels when war broke out between Mexico and the United States. With the appearance of U.S. troops under Commodore Robert Field Stockton and Capt. John Charles Frémont (*qq.v.*), the Mexican defenders of Los Angeles fled and the U.S. flag was raised over the city on Aug. 13, 1846. An insufficient garrison of 50 men, left in control, was compelled in October to withdraw because of a revolt of the inhabitants, and Los Angeles was not retaken until Gen. Stephen Watts Kearny and Commodore Stockton entered the city from San Diego in Jan. 1847.

After a short period as a military garrison Los Angeles reverted to civilian rule under U.S. control. On April 4, 1850, the city was incorporated and became the county seat, and in that year the first English-language school was opened and the first Protestant

church established. Los Angeles thrived upon a big cattle-trade with California's northern mines. At first a lawless frontier town, the files of the *Los Angeles Star*, southern California's first substantial newspaper, are filled with stories of almost routine daily violence during the 1850s and 1860s.

Until the building of the railroads, large-scale immigration remained limited by California's remoteness and isolation. Distance alone, not to speak of such natural barriers as deserts and almost impassable mountains, restricted communication with the rest of the world. Such travelers as ventured to the west in the two decades after the gold rush of 1848-49 tended to move toward San Francisco, then a larger, more cosmopolitan, better-known city. In 1869, however, the transcontinental railroad era dawned. Before that time (1866), Pres. Andrew Johnson confirmed the city's Spanish and Mexican pueblo land titles (consisting of 17,000 ac.). This action was particularly important as the claims of numerous residents under grants issued by the original pueblo rested on these titles.

Los Angeles finally attained a railroad connection with San Francisco in 1876, and with the eastern U.S., via the Santa Fe system, in 1885. An immense tide of immigration soon thereafter enveloped southern California, partly because of a vigorous rate war between the Southern Pacific and Santa Fe railroad companies. In the year 1887 railroad fares from Los Angeles to Chicago (and other Mississippi valley terminals) dropped to \$1. The dawn of the railroad age held commercial implications for Los Angeles as well as increasing its population. As early as 1877 local growers sent a carload of oranges eastward by rail. Then began a new era of horticultural enterprise. The railroad rate war and a simultaneous land boom soon created thousands of new customers for southern California's farmers and merchants. A significant proportion of the travelers to Los Angeles in the 1880s became permanent settlers. It is from the real estate boom of 1887 that the tourist era also dates.

But Los Angeles, located 20 mi. from the ocean, could not expect to become a great metropolis without a harbour. San Pedro, an open roadstead, with scanty protection from the sea, had served as its only port facility. Before a harbour was finally built, a long political battle ensued with Collis P. Huntington and Southern Pacific railway interests. These wanted a \$4,000,000 facility built, with government subsidy, at Santa Monica, rather than in the San Pedro-Wilmington area. The struggle over the site of the city's future harbour, with San Pedro favoured by a civic group known as the Free Harbour league, did not come to an end until 1896.

That year the U.S. congress voted an appropriation of \$2,900,000 to build an artificial harbour for Los Angeles at San Pedro, thereby defeating the Huntington interests. Three years later the city celebrated the Free Harbour jubilee and 20,000 persons gathered at San Pedro to watch the dumping of the first barge of stone for a breakwater. Construction of the harbour was finally completed in 1914 and, aided by traffic through the new Panama canal, Los Angeles began almost immediately to benefit by this new world trade route. Thereafter the history of Los Angeles was marked by continued commercial and industrial expansion.

Administration.—The city of Los Angeles is governed under a charter in operation from July 1, 1925. It provides for the initiative, the referendum, the recall and an executive budget. Elected at large are the mayor (the chief executive, with wide powers of appointment), the city attorney, the controller and seven members of the board of education. The 15 members of the city council (the legislative body) are elected by districts for a term of two years. They handle budget and tax problems, public improvements and local civil service matters. The principal functions of government are entrusted to 16 commissions of 5 members each, appointed by the mayor, which appoint and fix the salary of general managers for their departments. There is also a municipal housing commission consisting of 12 members together with 4 judges and the president of the chamber of commerce. All the above groups work in co-operation with a powerful board of county supervisors, who govern both urban and rural areas and control the many special districts and agencies in Los Angeles county.

Financial, Commercial and Industrial Development.—

In Southern California banking developed later and on a smaller scale than in the northern part of the state. Banks existed in San Francisco 15 years before they were established in Los Angeles. The first city bank was opened by Isaias W. Hellman in 1865. In 1868 Hellman bought out the rival bank of William Workman and his son-in-law Francisco P. F. Temple and in 1871 joined forces with California's Gov. John G. Downey to form the Farmers and Merchants bank, which became Los Angeles' first large bank. The development of the city as southern California's banking and financial centre was the natural outcome of population growth. Los Angeles has long been the home of numerous building and loan associations which have supplied much capital for real estate development. This capital is invested directly in land, buildings, oil and manufactures and there is also a large local investment in securities. The area is ranked as the third largest financial centre in the U.S. The economy of greater Los Angeles is exceedingly varied as well as dynamic. The reasons for its continuing prosperity are many and diverse.

Agriculture.—The city's first commerce was highly agricultural. Following the gold rush of 1848–49 the growth of population furnished an urgent market for cattle, grain and other foodstuffs. Prior to 1860 fully 60% of California's population was engaged in mining; the southern counties, of which Los Angeles was the centre, became the agricultural suppliers of this moneyed population. In 1850 cattle sold for as high as \$500 per head and the great ranches of the south flourished. Until drought conditions and falling prices in the 1860s damaged the sheep and cattle industries, Los Angeles was known as "queen of the cow counties." Grain, wheat and fruit production also made Los Angeles important agriculturally. Wine was made from the mission variety of grape from the early Spanish period. As early as 1831 there were about 100 ac. of vineyards at Los Angeles, containing about half of the state's 200,000 vines. The Camulos rancho at nearby Ventura was renowned for its fruit long before the gold rush occurred. William Wolfskill and Don Luis Vignes experimented on a small scale with the growing of grapes and oranges throughout the 1860s on the site of the modern downtown area.

It was the orange industry that first brought Los Angeles widespread agricultural acclaim. At nearby Riverside (*q.v.*) in 1873 Luther Calvin and Eliza Tibbets planted the first Washington navels, a new variety of seedless orange from Bahia, Braz. The climate and soil proved so well suited to this species of orange that it attained an agricultural perfection unmatched by any other fruit. The new industry added immeasurably to the commercial stability of Los Angeles. With the development of large-scale wine production at nearby Cucamonga, egg production in the San Fernando valley and a big dairy industry at Norwalk, Los Angeles achieved agricultural maturity well before the turn of the 20th century.

At mid-20th century Los Angeles county had led the nation in the value of its agricultural production each year since 1910. The city was a marketing centre for a wide diversity of crops, including oranges, lemons, apricots, peaches, almonds, walnuts, truck vegetables, figs, avocados, poultry, grain, alfalfa, livestock and dairying. The first outstanding success in co-operative farm marketing was made by the orange industry's local California Fruit Growers' exchange. This organization, as well as the California Walnut Grower's association, and the avocado and lemon exchanges, established headquarters in Los Angeles. However, agriculture steadily yielded large areas of fertile land formerly devoted to the raising of crops and livestock to real estate subdivisions, defense plants, new industrial establishments and space-consuming freeways. Los Angeles county's status as a leading county in agricultural production slipped markedly as the area became increasingly industrialized.

Manufactures.—Early manufacturing was chiefly for local needs and included such products as soap, confectioneries (utilizing locally grown sugar beets), beverages and brewing, as well as household goods. By 1925 Los Angeles, nevertheless, ranked first among California cities with a manufacturing output valued at more than \$500,000,000, a payroll of 58,000 and an annual wage expenditure of \$86,000,000. A significant feature of this development was the

shifting of manufacturing leadership from San Francisco to Los Angeles. In 1900 San Francisco ranked first among California's manufacturing cities but by 1910 had shown little increase in output while Los Angeles had advanced 100% in the same period. The shortages created by World War I further encouraged industrial enterprise at Los Angeles. World War II, with its Pacific fronts craving supplies, further stimulated, indeed forced, rapid industrial progress. By mid-20th century Los Angeles was a leading manufacturer of military and commercial aircraft.

After the war, the city had about 10,000 factories in the metropolitan area and by the early 1960s the number had increased to more than 16,000. Production of transportation equipment, motion pictures, fabricated metal products, machinery, petroleum products and printing formed a large part of this activity. Los Angeles also ranks as a fashion centre for sportswear and women's apparel; glass, chemicals, cement, paints, food processing and fish canning are also leading products. Until Japan entered the world market, southern California for decades had what amounted to a monopoly on the packing of tuna and Los Angeles became the largest fish-packing (including sardines) and fish-distributing centre in the U.S. Production of fish meal and fish oil are important by-products of this industry. Branch plants of eastern U.S. concerns are engaged in automobile assembling and the manufacture of tires, furniture, glass, textiles, tin cans, paper, steel and metal articles. Before the Fontana steel mill was built in 1942, Los Angeles foundries relied upon scrap and pig iron from England, Belgium and Utah and upon coke from Colorado.

Motion Pictures.—Reliable constancy of sunshine and varied scenery brought the motion-picture industry to Los Angeles. As late as 1909 only 4,000 people were living in Hollywood. At the turn of the decade, with ample land for studios, it became with Universal City, Burbank and Culver City an international centre for this industry. By the 1960s, however, television had changed the nature of the industry as even the largest studios gave way to the production of films for TV. At the height of its success Hollywood employed more than 100,000 persons in the making of films. (See HOLLYWOOD; MOTION PICTURES.)

Natural Resources.—Petroleum and water power were the first resources developed on a large scale. Electricity was generated in the mountains and Los Angeles pioneered long-distance electric power transmission and the linking of large electric networks. Within a radius of 300 mi. are valuable deposits of metals and minerals: copper, petroleum, soda, salt, potash, silica, infusorial earth, talc, graphite, limestone, building stone, marble and onyx. Except for utilization of borax and iron (from nearby Eagle mountain) these resources have not been widely exploited.

Associated with Los Angeles as much as oranges or motion pictures, however, has been large-scale oil production. A natural bituminous pitch, oozing out of the earth and called *brea*, was used by the Indians and early Spaniards to coat the roofs of their dwellings. After crude experiments to distill this product, in the 1850s and 1860s, there followed the colourful era of Edward L. Doheny who began the first widespread development of the gas and oil fields surrounding the city in the 1890s. Several oil companies were founded within the first decades of the 20th century and vast quantities of oil were taken from newly discovered Signal Hill (1921), Santa Fe Springs (1921) and Huntington Beach (1920). The production of these three nearby fields was so great that they frequently upset the national oil price, storage and distribution structure throughout the 1920s and 1930s. Hundreds of millions of barrels were produced by these and other Los Angeles wells. Not only did the petroleum industry enrich many individuals; it also became a great source of revenue for the state and provided widespread employment. The oil industry also helped make Los Angeles a transportation hub for ships, the railroad and, later, the trucking industry.

Transportation.—The development of transportation for Los Angeles has a long and colourful history. After U.S. occupation (1847) regular sea trade was established between San Pedro harbour and San Francisco, and mail was carried fortnightly by land between the latter city and Los Angeles. The first freight wagon overland from the east arrived in 1851, the first overland stage

in 1858. In 1860, a ten-day pony express linked Los Angeles with the Missouri river. A local railway from Los Angeles to San Pedro harbour was opened in 1869. The Southern Pacific railway from San Francisco to Los Angeles was completed in 1876. Until the Santa Fe connected the city with the east in 1885 the Southern Pacific company, under Collis P. Huntington, enjoyed a virtual monopoly of railroad transportation throughout California and into Los Angeles. By the 20th century this monopoly had been broken and the city had three direct railways to the east.

A municipal transport system of buses links the city with its harbour, beaches and various airports. At one time the Pacific Electric railway, a subsidiary of the Southern Pacific, had 1,161 mi. of track radiating from downtown Los Angeles to points as far outside the city as Redlands and Balboa beach. These inter-urban rail lines gave way to bus routes. Los Angeles is a terminal for various national highways and, because of the heaviest per capita density of automobiles in the world (more than 3,000,000 registered autos), is a natural centre for California's widespread freeway system (part of a master plan of highways to solve the traffic problem) which carries a heavy truck and bus traffic.

Los Angeles is also a travel centre for the southwest and several thousand visitors arrive daily by train, bus, car, ship and airplane. Hotels, apartment houses, motels and trailer courts cater to the tourist traffic.

Air service is available for transportation northward and eastward and Los Angeles has also become a terminus for the polar air route to Europe. Its International airport ranks high in the nation in volume of commercial passengers and freight. Other nearby airports are located in Van Nuys and at the Lockheed air terminal in Burbank.

The Port of Los Angeles.—By sea the city also maintains shipping connections to all parts of the globe, as well as a coastal traffic to both Pacific and Atlantic ports of North and South America. In Spanish times San Pedro bay afforded an uncertain roadstead, chosen because of accessibility by level land route to the city. Despite a stage route (1852) to the harbour and later a railroad, San Francisco enjoyed most of the sea trade in the 19th century. The lengthy squabble over the future site of Los Angeles harbour ended with the annexation in 1906 of the "shoestring strip" to the ocean, giving Los Angeles municipal jurisdiction over its future harbour, the annexation of San Pedro and Wilmington (1909), the building of a breakwater by the U.S. government (1910) and of an inner harbour by the city itself (1912-14). Cargo shipments increased eight times in both tonnage and value, in the decade 1920-30. With more than 40 mi. of water front, and superior accommodations for large ocean-going vessels, facilities were enlarged in 1941 in co-operation with the separate harbour at Long Beach. After World War II Los Angeles became, in total volume, one of the largest export harbours in the U.S. Chief imports are bananas, newsprint, copra, rubber, coffee, sodium nitrate, jute, iron and steel scrap, vegetable oil and fibres. Chief exports include oil, cotton, borax, citrus fruits, asphalt, steel plates, industrial chemicals, pipes, tubes and fittings, canned fish, machinery, chemicals and automobile tires. Los Angeles harbour is an operating centre for the U.S. navy.

Water Supply.—Los Angeles required an unrelenting supply of water for industrial and domestic purposes. Located in a semi-desert region, water was crucial to its growth. In 1904 William Mulholland, chief engineer of the city's water department, suggested an aqueduct to the Sierra Nevada range through the Mojave desert. By 1908 city bonds were voted, and work begun upon a most controversial project which virtually depleted Owens lake and turned part of the southern Sierra into a desert wasteland. Los Angeles aqueduct, finished in 1913, was 233 mi. in length and the longest work of its kind in the world. The cost of construction was nearly \$25,000,000, including 142 tunnels, 97 mi. of covered conduit, 12 mi. of siphons, 39 mi. of lined canal, and 24 mi. of unlined canal. Despite a daily capacity of 288,000,000 gal., and additional water supplies from the Los Angeles river, by the 1930s the city began to fall seriously behind in its water requirements. Construction in 1936 of the giant Colorado river (*q.v.*) aqueduct, part of a \$220,000,000 project piercing six mountain ranges

with 38 tunnels totaling 108 mi., afforded an additional allotment of 677,000,000 gal. daily and provided a new water supply to 13 cities in the metropolitan district. The major electrical energy comes over a transmission line of 266 mi. from Hoover (formerly Boulder) dam. By the 1950s the city was keenly aware that new sources of water supply would have to be developed. However, California's water problems became ensnarled in a bitter north-south sectional controversy over retention of water rights by northern "counties of origin" which were reluctant to release further water resources to a seemingly insatiable Los Angeles. The north needed flood control projects almost as much as the south needed water, but political factionalism stymied co-operation in launching such remedial programs as the controversial Feather river project, which finally was begun officially in 1960.

Cultural and Educational Activities.—In addition to its numerous well-known "motion-picture palaces," Los Angeles supports considerable legitimate theatre. Hollywood is the centre of energetic little-theatre activity. The Player's Ring, Huntington-Hartford theatre and Pasadena's Community playhouse are familiar sites. Extensive television and radio facilities have been built in Los Angeles, from which many national and regional network programs emanate.

Grand opera is usually presented in Shrine auditorium, seating 7,000 persons. Orchestra programs and other recitals are given in the Philharmonic auditorium. As the climate makes outdoor entertainment attractive, the city has a number of gathering places such as the Los Angeles coliseum seating 105,000 persons, a sports arena for athletic events and conventions (35,000), Hollywood Bowl (25,000), the adjoining Pilgrimage Play amphitheatre and outlying auditoriums, such as the Pasadena Rose Bowl (89,000). The *Symphony Under the Stars* is presented in Hollywood Bowl and ballet and outdoor drama are presented each summer at the municipal Greek theatre in Griffith park.

The Los Angeles County Museum of History, Science, and Art in Exposition park exhibits skeletons of prehistoric mammals from nearby La Brea pits. It also maintains an important art museum located near the state museum of science and industry. The Southwest museum at Highland Park specializes in the civilizations of the southwestern United States, Mexico and Central America and is particularly strong in materials concerning the American Indian. Its Casa de Adobe is a replica of an early Spanish colonial home, complete with furnishings. At Barnsdall park, in Hollywood house, a structure of Mayan inspiration, built in 1913 by Frank Lloyd Wright, is located the Municipal Art gallery, the site also of cultural activities and small musicales. City zoos are located at Elysian and Griffith parks. At Griffith observatory are 12- and 6-in. refracting telescopes, a 3-in. solar telescope; a museum of the physical sciences; and a planetarium.

The Los Angeles public library with more than 60 branches has about 2,250,000 volumes. The Los Angeles county public library, also with more than 60 branches, has over 1,000,000 volumes. The city has special libraries belonging to colleges, professional associations and business concerns, devoted to law, medicine, architecture, mining, petroleum, minerals and industrial subjects. One of these is the William Andrews Clark library of the University of California (devoted to the collection of books on Anglo-American civilization); and the Henry E. Huntington library and art gallery (at nearby San Marino) is rich in rare books and manuscripts, mostly English and American, with collections of incunabula. There is also an outstanding collection of portraits and landscapes of the English painters of the "golden age"—Thomas Gainsborough, Sir Joshua Reynolds, Sir Thomas Lawrence and George Romney. The J. Paul Getty museum, near Santa Monica, includes collections in two major fields: French 18th-century art and Greek and Roman sculpture.

Enrollment in the Los Angeles public schools during the early 1960s totaled more than 600,000. In a 15-year period after World War II, enrollment in the city's high schools increased by 60% while elementary school growth during the same period was 75%.

Among the major institutions for higher education, in order of their founding, are: (1) the private coeducational University of Southern California (1880), in the central part of the city; (2)

Occidental college (1887), located on an attractive campus in the Eagle Rock section, at the northern border of Los Angeles, a private coeducational college devoted to the liberal arts and sciences; (3) California Institute of Technology (1891), at Pasadena, a private institution whose work is largely confined to scientific and engineering subjects; it is notable for pure science and research. At the Institute's Jet Propulsion laboratory the United States' first earth satellites were constructed in 1957; (4) Loyola University of Los Angeles (1911), Roman Catholic, with courses in engineering, commerce, premedical studies and law; (5) the public University of California at Los Angeles (1919), on a huge, sprawling campus at the western border of the city; it is increasingly graduate in character, but gives complete university training. Its facilities include schools of law, medicine and engineering. Other nearby public institutions are Los Angeles state college (1947) and San Fernando Valley state college (1956). Located in greater Los Angeles are Whittier college (1901); the Associated colleges, five institutions at Claremont, and Redlands university (1907). All except the state institutions were founded by religious denominations but, by agreement with their respective churches, many gave up all organic denominational connection early in the 20th century.

Parks and Recreation.—Los Angeles city and county maintain several hundred parks, playgrounds, swimming pools and youth centres. Among these are: Griffith park, 4,253 ac.; Exposition park, 114 ac., with Los Angeles museum; Elysian park, 599 ac., in a natural state; Sycamore grove, 15 ac.; Lincoln park, 46 ac.; and Pershing square, the only park in the business section besides the old Spanish plaza. At the latter is the old Plaza church, one of the plaza's many historic buildings dating from the period 1800–12 onward. Nearby are the Lugo house, the city's first multi-story building, dating from 1840 when it was built by Don Vicente Lugo; it was later used for a time by St. Vincent's college (later Loyola university) as its first campus. Olvera street, called El Paseo by the Spaniards, is a brick walkway named for Don Agustin Olvera, and visited traditionally by tourists. Avila adobe, a private museum on this street, was built in 1818 by Don Francisco Ávila; surrounding it are several dozen shops, including several candlemaking establishments, that sell Mexican handicrafts. Also near the Plaza and Olvera street there stands the Pico house, a hotel on Main street built in 1869 by Gov. Pio Pico.

Another tourist attraction is La Brea pits. Located farther west on Wilshire boulevard, the "pitch springs," as they were known when utilized by the Indians, were discovered by the Portolá expedition of 1769. These fossil-bearing tar pits, containing prehistoric remains of extinct animals once caught in sticky seepage, came into the possession of G. Allan Hancock, who gave them to the city in 1915 for park development purposes. Hancock park now contains life-size restorations of such prehistoric animals as the sabre-toothed tiger, mastodon, giant ground sloth and prehistoric camels and bison.

Many tourists visit Mt. Wilson, site of the 100-in. Carnegie telescope located northeast of the city, Lake Arrowhead and Big Bear lake in the San Bernardino mountains and Santa Catalina Island, 23 mi. S.W. from San Pedro. Other attractions include Disneyland, Knott's berry farm, Pacific Ocean park and the Marineland of the Pacific, an oceanarium near Palos Verdes.

Since 1957 Los Angeles has been the home of the former Brooklyn Dodgers, a professional major (National) league baseball club. In 1961 the Los Angeles Angels, an American league club, began play. The Los Angeles (formerly Cleveland) Rams of the professional National Football league are also located there.

City Planning and Problems of Growth.—Once a sleepy pueblo of red-tiled, whitewashed adobe buildings and muddy streets, the town presented a distinctive impression upon travelers in former times. Its population at the turn of the 20th century was 102,489 inhabitants. Baedeker's *Guide* said in 1899 that within the preceding decade "its adobe houses have given place almost entirely to stone and brick business blocks and tasteful wooden houses." The typical "California house" of the early 20th century was frequently an adaptation of Spanish design and the bungalow from India. In fact, southern California's architecture

is still highly eclectic. The Monterey-style house, with its balconies and terraces, became especially popular. Stucco or wood frame construction were alternately featured by builders who pioneered real estate tracts that mushroomed interminably in a horizontal construction boom that eventually obliterated the Los Angeles countryside.

Only after 1925 did the city develop a real civic centre, with its nearby Spanish-style union passenger railroad terminal and accompanying government buildings. By the 1960s these developments were giving way to massive redesigning of the city's entire civic centre. A central mall became the site of a series of city, county, state and federal buildings. Slum clearance and relocation developments were simultaneously transforming the Bunker Hill region into a new commercial and residential area. After the removal in 1957 of a 150-ft. height maximum on public buildings came the construction of many 20- to 40-story buildings that line 15 mi. of the city's central sector and its westward extension into the Wilshire boulevard district with an increasingly vertical skyline of apartment houses and office buildings.

Construction of freeways, parks, airfields, schools, fire stations, libraries, sewers and other facilities on the city's expanding periphery barely kept up with the population avalanche that came to Los Angeles after World War II. Statistics for the 1950s indicated that on the average one new person entered southern California every 55 seconds. A new school was needed for additional pupils every Monday morning into the 1960s. Each year Los Angeles added a city larger than Syracuse, N.Y. The costs of such expansion were great as municipal plans became obsolete even before they emerged from blueprints.

All this frenzied growth was not without concern to those residents who knew the city when it was a pleasanter place in which to live. The smog, increased traffic congestion, industrialization and other municipal problems decreased the charm of rural and suburban living. The traditionally colourful orange groves and vineyards made way for aircraft factories, steel mills, housing developments and large apartment construction. Nevertheless there was no evidence that migration to southern California in general, and Los Angeles in particular, would taper off. The pattern indicated the city would move outward to swallow up even more of its countryside. Population experts predicted a vast urban complex stretching almost solidly from Santa Barbara to San Diego, its centre—and controlling focus—Los Angeles.

LOS ISLANDS (ÎLES DE LOOS), a group of islets just off Conakry, the capital of the Republic of Guinea, west Africa. There are five principal islands: Tamara, Kassa, Roume, Bianche and De Corail. The first two are the largest, Tamara being about 8 mi. long and 1–2 mi. broad. Tamara and Kassa lie parallel to one another, Tamara to the west; they form a sort of basin, the centre of which is the islet of Roume. The other two islands are to the south. The highest point is a knoll of 499 ft. on Tamara. All the islands are richly clothed with palms and flowering underbrush. The inhabitants, about 1,500, are immigrants of the Baga (q.v.) tribe.

Tamara has a good harbour, but the wealth of the islands derives from the bauxite obtained from the volcanic rocks (nepheline syenite) of which they are composed. The deposits, first exploited in 1949, are worked by opencast mining and by the late 1950s yielded about 400,000 tons annually.

The Los Islands derive their name from the sacred idols (*les idoles*) found there by the early European navigators. In 1818 the governor of Sierra Leone obtained the cession of the islands from the Baga chiefs and in 1882 France recognized the group as

a British possession. However, because of their proximity to Conakry, they were ceded to France by the Anglo-French convention of April 8, 1904. In 1958 the islands became part of the independent Republic of Guinea. (J. D.)

LOS RÍOS, province in the coastal lowland of Ecuador, bounded west by Guayas, north by Pichincha and Cotopaxi, east by Bolívar and south by Guayas. Area, 2,292 sq.mi. Pop. (1960 est.) 219,800. Its capital is Babahoyo, pop. (1959 est.) 13,100. The province is mostly in the lowlands west of the mountains, along the middle courses of the Vines and Babahoyo rivers, tributaries of the Guayas. The chief land use is for beef cattle, bananas, cacao, sugar cane and rice. From the forests come balsa wood, timber, tagua nuts and rubber. As the name suggests, transportation is almost entirely by river boat to Guayaquil. Steamers reach Babahoyo even during the dry season and in flood season can ascend to Zapotal. (P. E. J.)

LOS SANTOS, a small province in southern Panama occupying much of the hilly Azuero peninsula and facing the Gulf of Panama. Area, 1,494 sq.mi. Pop. (1960) 70,554, of which 70% was rural. The largest town and capital is Las Tablas, pop. (1960) 3,504; it is 8 mi. N.W. of the port of Mensabé. Los Santos is important agriculturally, ranking high in the production of corn, rice, sugar, swine, cattle and poultry. The province is a major supplier of eggs and chickens to the urban centres in and near the Canal Zone, to which it ships products by boat and truck. (C. F. J.)

LOSSIEMOUTH AND BRANDERBURGH, a seaport and small burgh of Moray, Scot., at the mouth of the Lossie on the Moray firth, 5½ mi. N. of Elgin. Pop. of burgh (1961) 5,855. Lossiemouth, or the old town, dates from 1700; Seatown is somewhat later; Branderburgh, farther north, grew with the harbour and began about 1830; and Stotfield is now purely modern, although on the site of the oldest settlement. In the 15th century Lossiemouth succeeded Spynie as Elgin's port, when that town was silted up by sand and shingle, but it declined with the migration of the herring until its popularity as a seaside town brought back its prosperity. There are long sandy beaches and a fine golf course. Fishing is still the main industry (whitefish only) and the town has a fleet of 80 seine-net boats. J. Ramsay MacDonald (1866–1937), the first Labour prime minister, was born in Lossiemouth. The cliffs at Covesea, 2 mi. W., contain caves, in one of which prehistoric weapons were found and the roof of another is carved with early Celtic ornamentation. On the coast is Covesea lighthouse.

Nearly midway between Lossiemouth and Elgin stand the massive ruins of the palace of Spynie, formerly the castle of the bishops of Moray. The larger tower, with walls nine feet thick, was built about 1470.

LOSSKI, NIKOLAI ONUFRIEVICH (1870–), Russian philosopher, was born at Kreslavka near Vitebsk on Dec. 6, 1870. He was educated at Kreslavka and at the University of St. Petersburg, where he was professor, 1916–21. In 1922 he was compelled to leave the U.S.S.R. and went to live in Prague, Czech. He was a professor in Bratislava, 1942–45. After World War II he emigrated to the U.S. and became a professor in the Russian Orthodox seminary, New York (professor emeritus, 1950). According to Losski's views, knowledge is immediate contemplation (intuition). His intuitionism differs from Bergson's insofar as he considers the ideal-rational forms to be elements of realities, intuitively cognizable. Losski assumes not only concrete real being, but concrete ideal being as well; i.e., supratemporal and supraspatial substantial agents with creative force, which are the basis of spatiotemporal being. This doctrine leads Losski to his teaching of the freedom of the will. Among Losski's most important books are *Die Grundlehre der Psychologie vom Standpunkte des Voluntarismus*, published in Russian (1903), in German (1905); *The Intuitive Bases of Knowledge* (1904; Eng. trans., 1919); *Handbuch der Logik* (1922); *The World as an Organic Whole* (Eng. trans., 1928); *Freedom of Will* (Eng. trans., 1932); *Value and Existence* (Eng. trans., 1935); *Des conditions de la morale absolue* (French trans., from Russian manuscript, 1948); and *History of Russian Philosophy* (1951).

LOSTWITHIEL, a market town and municipal borough (1885) in the Bodmin parliamentary division of Cornwall, Eng., on the Fowey river, 6 mi. S.S.E. of Bodmin. Pop. (1961) 1,954. St. Bartholomew's church has a fine Early English tower and a Decorated spire. A bridge of the 14th or early 15th century crosses the river. The Shire hall or Duchy palace includes remains of the 13th-century Stannary prison. The Western Region railway route has workshops there. The boundaries of the borough were further extended in 1934 to include parts of the parishes of St. Winnow, Lanlivery and Lanhydrock.

Lostwithiel probably owed its existence to the neighbouring circular castle of Restormel, restored in 1930. The first charter dates back to about 1190. The Pipe Rolls (1194–1203) show that Robert de Cardinan, lord of Restormel, paid ten marks yearly for having a market at Lostwithiel. He surrendered to the burgesses all the liberties given them by his predecessors (*antecessores*) when they founded the town. Isolda, granddaughter of Robert de Cardinan, gave the town to Richard, king of the Romans, who granted to the burgesses a guild merchant and many privileges, as well as a yearly fair and a weekly market. His son Edmund decreed that the coinage of tin should be at Lostwithiel only. In 1609 a charter of incorporation provided for courts of record and piepowder. From 1305 to 1832 two members represented Lostwithiel in parliament, but under the Reform act (1832) the town became merged in the county.

For the victory gained by Charles I over the earl of Essex in 1644, see CIVIL WAR, ENGLISH.

LOT, in the Bible, the legendary ancestor of the two Palestinian peoples, Moab and Ammon (Gen. xix, 30–38; cf. Ps. lxxxiii, 8); he appears to have been represented as a Horite or Edomite. As the son of Haran and grandson of Terah, he was Abraham's nephew, and he accompanied his uncle in his migration from Haran (Harran) to Canaan. Near Bethel Lot separated from Abraham because of disputes between their shepherds and, being offered the first choice, chose the fertile and well-irrigated Jordan valley. It was in this district that the cities of Sodom and Gomorrah (*q.v.*) were situated. He was saved from their fate by two divine messengers who spent the night in his house, and next morning led Lot, his wife and his two unmarried daughters out of the city. His wife looked back and was changed to a pillar of salt, but Lot with his two daughters escaped first to Zoar and then to the mountains east of the Dead sea, where the daughters planned and executed an incest by which they became the mothers of Moab and Ben-Ammi (i.e., Ammon). The account of Chedorlaomer's invasion and of Lot's rescue by Abraham, recounted in Gen. xiv, belongs to an independent source, the age and historical value of which have been much disputed. See ABRAHAM; AMMONITES; MOAB.

LOT, an inland *département* of southwestern France, was formed in 1790 from the district of Quercy in the old province of Guienne (*q.v.*). It is bounded north by Corrèze, east by Cantal and Aveyron, south by Tarn-et-Garonne and west by Lot-et-Garonne and Dordogne. Area 2,018 sq.mi. Pop. (1962) 149,929. In the east the *département* rises above 2,000 ft. on the rolling crystalline plateaus, known as Ségalas (rye lands), that form the western flanks of the Massif Central, but the greater part consists of dry limestone platforms, between 800 and 1,500 ft., called Causses. They are less elevated than the Grands Causses of the Tarn and Aveyron basins farther southeast and are sometimes known collectively as the Petits Causses. The Lot river, crossing the Causses from east to west in a deep, steep-sided valley that opens out about Cahors, separates the Causse de Cahors to the south from the Causse de Gramat, which stretches north to the parallel valley of the Dordogne river in the northern extremity of the *département*. Although less severe than the Grands Causses, the limestone plateaus show the characteristic feature of underground drainage, with numerous swallow holes and grottoes. Their stony surfaces are often suited only for sheep pasture, but there are some woodlands of stunted oak and juniper, and truffles are renowned as a local speciality. In hollows, where pockets of soil have accumulated, some cultivation is carried on. The agricultural wealth lies in the warm and sheltered valleys. There a variety of crops flourish, including grain, vine and fruits, often grown on

terraced slopes, while the flat valley floors are ribbons of irrigated meadows. There is little mineral wealth, but the limestone is quarried in places. Although the main railway from Paris to Toulouse traverses the *département* from north to south through Cahors, the area is a rural backwater. Another railway follows a more easterly route along the Lias marl groove at the contact of the crystalline and limestone plateaus, where the small market towns of Figeac and St. Céré are situated.

Cahors, the largest town (pop. [1962] 15,528), is also the capital of the *département* and centre of the bishopric that is co-extensive. Its cathedral is notable for its cupolas, and Souillac also has a famous Romanesque church with cupolas, as well as a remarkable sculptured portal. The village of Rocamadour is picturesquely situated in a gorge beneath a 400-ft. wall of rock, which carries the famous sanctuaries that make it a pilgrimage centre. The *département* is divided into three *arrondissements* centred upon Cahors, Figeac and Gourdon. It comes under the educational administration of Toulouse and is served by the court of appeal at Agen. (AR. E. S.)

LOTA, major coal mining centre in southern Chile, located on the Gulf of Arauco. Although it was founded in 1662, sustained development of the city did not begin until 1852, when Matías Cousiño began a coal mining enterprise. The completion of a railway from Concepción in 1888 stimulated the growth of Lota by providing land transportation for the coal, which is taken from seams that lie below the gulf floor to about 3½ mi. offshore. Other industries in Lota include a brick and refractories plant and a copper smelter, and there are also extensive pine and eucalyptus plantations in the surrounding area. Operating and administrative facilities and a planned company town comprise Lota Alto; together with Lota Bajo, a commercial and residential community, Lota's population (1960) is 51,679 (mun.). Renowned in Chile for its beauty is the splendid Isidora Cousiño park. (J. T.)

LOT-ET-GARONNE, an inland *département* of southwestern France, was formed in 1790 from the Agenais and Bazadais portions of ancient Guyenne (Guienne) and the Condomois Lomagne, Brullois and Albret districts of Gascony. It is bounded north by Dordogne, east by Lot and Tarn-et-Garonne, south by Gers and west by Landes and Gironde. Area 5,385 sq.km. (2,079 sq.mi.). Pop. (1962) 275,028. The Garonne river crosses the *département* from southeast to northwest, receiving an important tributary, the Lot, in the centre. The broad, alluvial valleys of the great rivers are flanked by undulating platforms of marly limestones and clays that give fertile, if rather heavy, soils. There is little mineral wealth or manufacturing, but agriculture is productive. Both wheat and maize, as well as fodder crops, are widely cultivated; the vine is ubiquitous; and much fruit, including peaches, apricots and plums, is grown. *Prunes d'Agen* are well-known confections. Some of the wine is distilled into brandy. Tobacco is extensively cultivated for the state factory at Tonneins. Cattle, pigs and poultry are kept in large numbers, and geese are fed on maize for *pâté de foie gras*. The *département* extends westward to include the easternmost prong of the great Landes forest (see LANDES, LES), and Casteljalous on its margin has a paper mill and other woodworking industries.

Agen (*q.v.*), the capital, is the seat of a bishopric, with the impressive cathedral of St. Caprais, and also has a court of appeal; for educational administration, however, the *département* comes under the *académie* of Bordeaux. The *département* is divided into three *arrondissements*, centred upon Agen, Marmande and Villeneuve-sur-Lot, all modest country market towns characteristically situated on the great rivers. Navigation is carried on by the lateral canal along the Garonne valley. Villeneuve-sur-Lot, dating from 1264, is a noteworthy example of the medieval planned towns, laid out in a regular grid, that are numerous in the lowlands of Aquitaine. The Romanesque abbey church of St. Pierre at Moissac has beautiful cloisters and an elaborate doorway.

The history of the *département* is associated with Agenais, Guienne and Gascony (*qq.v.*). (AR. E. S.)

LOTHAIR I (795–855), Frankish emperor of the Carolingian dynasty, was the eldest son of the future emperor Louis I (*q.v.*) the Pious and his first wife, Irmingard. He probably grew up in

Aquitaine when his father was king there. After Louis had become co-emperor (813) and successor of Charlemagne (814), he made Lothair king in Bavaria and, in 817, joint emperor. The *Ordinatio imperii* of 817 was designed to provide for the unity of the Frankish empire after Louis I's death: Lothair's younger brothers Pepin and Louis (later called the German) were to receive their own kingdoms, namely Aquitaine and Bavaria, but were to remain under the imperial suzerainty of Lothair. In 821 Lothair married Irmingard (d. 851), daughter of Count Hugh of Tours.

Ruler in Italy from 822, Lothair was crowned emperor again by Pope Paschal I, on April 5, 823. In 824 he issued the *Constitutio Romana*, which affirmed imperial sovereignty over Rome and demanded an oath of fealty from the pope. Then, in 829, Louis the Pious, under the influence of his second wife Judith and in violation of the *Ordinatio* of 817, granted part of the empire to his son by Judith, Charles (later called the Bald). This made Lothair break with the imperial government. Though a palace revolution enforced his reappointment as co-emperor in 830, he was again deposed shortly afterward. In 833, however, discontent at the rule of Louis the Pious culminated in a revolt of the three elder sons, led by Lothair; and Louis was deposed in Lothair's favour. As Lothair soon made himself hated for his egotism and favouritism, Louis was restored in 834 and Lothair's rule restricted to Italy. Thus the ideal of imperial unity collapsed.

When Louis I died (840), Lothair claimed again his rights under the *Ordinatio*; but his brothers, Louis the German and Charles the Bald (Pepin had died in 838), opposed him, and he was defeated in battle at Fontenoy near Auxerre on June 25, 841. The treaty of Verdun (Aug. 843) left him the "Middle Realm" of the Frankish dominions, stretching from the North sea to Italy, while Louis had the eastern and Charles the western territory, so that imperial supremacy was replaced by the joint rule of the three brothers. Lothair adhered loyally to this system and tried at several conferences (Thionville, 844; Mersen or Meerssen, 847 and 851) to iron out the differences between him and his brothers. In his own realm he reverted to subdivision, making the government of Italy over to his eldest son Louis II as early as 844 and partitioning his realm between his sons Louis (emperor from 850), Lothair and Charles (who received Provence) in Sept. 855. Then he abdicated and became a monk at Prüm, where he died a few days later, on Sept. 29, 855, and where he is buried.

See F. Lot and F. Ganshof, *Les Destinées de l'empire en Occident* (1941); T. Mayer, *Der Vertrag von Verdun* (1943). (T. Sca.)

LOTHAIR II or III (1075–1137), German king from 1125 (reckoned as Lothair III by those who count not only the elder but also the younger Carolingian Lothair in their numeration of sovereigns over parts of Germany) and Holy Roman emperor from 1133, also duke of Saxony from 1106, was the son of Gebhard, count of Supplinburg. He succeeded to extensive lands around Helmstedt, in Saxony, on his father's death in battle a few days after his birth (June 1075). Gebhard had been a leading opponent of the emperor Henry IV (see HENRY, German kings), and Lothair, taking the same attitude, assisted Egbert II of Meissen in the rising of 1088. His position in Saxony was enhanced by his marriage with Richenza, daughter of Henry of Nordheim.

Having assisted the German king Henry V against his father in 1104, Lothair was appointed duke of Saxony by Henry V, when Duke Magnus, the last of the Billungs, died in 1106. His independent attitude brought him into collision with Henry V, to whom, however, he was forced to submit after an unsuccessful rising in 1112. In 1112 Lothair supported the claim of Siegfried, count of Ballenstedt, to inherit the domains of Ulrich II, count of Weimar and Orlamünde, against Henry V. The rebels were defeated, and Siegfried was killed at Wernstedt in 1113, but his son secured possession of the disputed counties. After the defeat of Henry's forces by Lothair at Welfesholz on Feb. 11, 1115, events called Henry to Italy; and Lothair appears to have been undisturbed in Saxony until 1123, when the death of Henry II, margrave of Meissen and Lusatia, raised a dispute as to the right of appointment to the vacant margraviates. A struggle ensued, in which Lothair prevailed.

When Henry V died in 1125, Lothair was elected German king at Mainz on Aug. 30, largely thanks to the efforts of the papal party, and crowned at Aachen on Sept. 13. He requested Frederick of Hohenstaufen to restore to the crown the estates bequeathed to him by Henry V. Frederick refused and was outlawed. Lothair, unable to capture Nürnberg, gained the support of the Welf Henry (q.v.) the Proud, the new duke of Bavaria, by giving him his daughter Gertrude in marriage, and that of Conrad, count of Zähringen, by granting him the administration of the kingdom of Aries. But Conrad of Hohenstaufen, Frederick's brother, was elected as antiking in Dec. 1127 and was quickly recognized in northern Italy. But by the end of 1129 the Hohenstaufen strongholds Nürnberg and Speyer were in Lothair's possession. This struggle was accompanied by disturbances in Lorraine, Saxony and Thuringia, but order was soon restored after Hohenstaufen resistance had been beaten down. In 1131 the king led an expedition into Denmark but met resistance and withdrew on securing a promise of tribute.

The king's attention at the time was called to Italy where Pope Innocent II and Anacletus II were clamouring for his support. At first Lothair remained neutral; but in March 1131 he was visited at Liège by Innocent, to whom he promised his assistance. Leaving Germany with a small army in Aug. 1132, he reached Rome in April 1133, accompanied by Innocent. As St. Peter's was held by Anacletus, Lothair's coronation as emperor took place in the church of the Lateran on June 4, 1133. He then received as papal fiefs the vast estates of Matilda of Tuscany, thus securing for his daughter and her Welf husband lands which might otherwise have passed to the Hohenstaufen. He returned to Germany, where he restored order in Bavaria and on the lower Rhine. Resuming the struggle against the Hohenstaufen, he soon obtained their submission, though they retained their lands. A general peace was sworn at Bamberg. The emperor's authority was now generally recognized, and the annalists speak highly of the peace and order of his later years.

The emperor seconded the efforts of his vassals Albert the Bear, margrave of the Saxon North mark, and Conrad I, margrave of Meissen and Lusatia, to extend the authority of the Germans in the districts east of the Elbe, and he assisted Norbert, archbishop of Magdeburg, and Albert I, archbishop of Bremen, to spread Christianity. In 1135 Eric II of Denmark acknowledged himself a vassal of Lothair; the Polish prince Boleslaw III promised tribute and received Pomerania and Rügen as German fiefs; and the Byzantine emperor John Comnenus solicited Lothair's aid against Roger II of Sicily.

In Aug. 1136, attended by a large army, Lothair set out on his second Italian journey. The Lombard cities were either terrified into submission or taken by storm; Roger II was driven from Apulia; and the imperial power was enforced over the whole of southern Italy. A mutiny among the German soldiers and a breach with Innocent over the overlordship of Apulia compelled the emperor to retrace his steps. After making an arrangement about Apulia, Lothair left Italy for Germany but died at Breitenwang in Tirol on Dec. 3 or 4, 1137.

BIBLIOGRAPHY.—The official acts of the reign are published in the *Monumenta Germaniae Historica*, ed. by E. von Ottenthal and H. Hirsch, *Die Urkunden Lothars II. und der Kaiserin Richenza* (1927). See also W. Bernhardt, *Lothar von Supplinburg* (1879); A. L. Poole, "Germany 1125-1152," *Cambridge Medieval History*, vol. v, rev. ed. (1943, 1948); K. Hampe, *Deutsche Kaisergeschichte*, 10th ed. (1949).

LOTHAIR (941-986), king of France from 954 to 986, of the Carolingian dynasty, was the son of Louis IV d'Outremer and of Gerberga, sister of the German king Otto I. After his father's death he was elected king without opposition (Nov. 12, 954), but he was dominated first by Hugh (q.v.) the Great and then by Otto I's brother, Archbishop Bruno of Cologne. Bruno furthered Otto's policy of maintaining a balance of power in France between the Carolingian rulers and their Robertian rivals and persuaded Lothair not to annex Burgundy but to give the duchy to Otto, a son of Hugh the Great. Lothair was forced to attend a council held by Otto I at Cologne in June 965, and in the same year he married Otto's stepdaughter Emma.

Lothair failed to profit from the freedom brought by Bruno's death late in 965. Though he preserved his domain carefully, he was much distracted by feudal conflict. Also a persistent desire to get Lorraine from the German allegiance brought disastrous consequences: his support of a feudal revolt there (976) against Otto II impelled the latter to give the duchy of Lower Lorraine to Lothair's refractory brother Charles (q.v.); his plan to capture Otto's family at Aachen (978) miscarried and provoked a retaliatory raid into France; and a third invasion of Lorraine (985) not only failed in its purpose but determined the powerful Archbishop Adalberon of Reims to support the Robertian Hugh Capet against Lothair. Lothair was, however, preparing yet another expedition into Lorraine when he died on March 2, 986.

See F. Lot, *Les derniers carolingiens* (1891).

(J. De.)

LOTHAIR (c. 835-869), Frankish king from 855 of the country known as Lotharingia (*Lotharii regnum*, or Lothair's kingdom; see LORRAINE), was the second son of the Carolingian emperor Lothair I. When his father's "Middle Realm" was divided in 855 young Lothair received the area west of the Rhine from the North sea to the Alps. When his brother Charles of Provence died in 863, Lothair's kingdom was extended beyond Lyons, but his reign was an unending struggle for the future of this kingdom and his dynasty. In 855 he had married Theutberga, sister of Hucbert, the lay abbot of St. Maurice, but she remained childless and from 857 Lothair was trying to have the marriage dissolved and to make his mistress Waldrada, who had given him a son Hugh, his legitimate wife and queen. He made odious accusations against Theutberga (accusing her of incest with Hucbert), but her champion prevailed in the ordeal by boiling water (858) and she had to be taken back. Lothair then secured the support of his eldest brother the emperor Louis II by granting him some territory and induced two subservient archbishops, Günther of Cologne and Theutgaud of Trier, to start ecclesiastical proceedings against his wife. Two synods at Aachen dissolved his marriage after Theutberga had been compelled to make a "confession" (860), but she fled to the West Frankish king Charles the Bald, revoked her confession and appealed to Pope Nicholas I. Nevertheless a third synod at Aachen (April 862) gave Lothair permission to marry Waldrada; and he obtained the papal legate's confirmation of this decision, probably through bribery, at a synod at Metz (June 863). Nicholas quashed these decisions and deposed the two archbishops (Oct. 863), and another legate forced Lothair to take Theutberga back again (Aug. 865). Then Lothair made her ask Pope Adrian II for a divorce herself (867), and the pope received him in 869. Expecting a fresh trial, Lothair was going home when he died at Piacenza on Aug. 8, 869. He is buried at Piacenza. The treaty of Mersen (Meerssen) in 870 divided his realm between the West and the East Frankish kingdoms.

LOTHARINGIA: see LORRAINE.

LOTHIAN, PHILIP HENRY KERR, 11TH MARQUESS OF (1882-1940), who as British ambassador to Washington from April 1939 was, after the outbreak of World War II, a superlative exponent of the British cause to a still neutral United States and displayed notable qualities as a negotiator in such matters as the destroyer bases deal. He was born in London on April 18, 1882, and was educated at the Oratory school, Birmingham, and at New College, Oxford. In 1905 he was appointed assistant secretary of the intercolonial council of the Transvaal and the Orange River colony and of the railway committee of Central South African railways. In these capacities he went to South Africa, becoming a member of the so-called "kindergarten" of Sir Alfred Milner, afterward Viscount Milner, and remaining there until 1910 as an active advocate of South African federation. After his return to England he became editor (1910-16) of the *Round Table*, a journal advocating closer imperial unity. He was secretary to Lloyd George from 1916 to 1921, in which year he became political director of the *Daily Chronicle*, having been already, since 1918, a director of the United Newspapers. He served in the cabinet as parliamentary undersecretary of the India

office (1931–32), was chairman of the Indian Franchise committee (1932) and secretary (1925–39) of the Rhodes trust which administers the Rhodes scholarships. He was appointed ambassador to the United States on April 24, 1939, a position he held until his tragically premature death in Washington, D.C., on Dec. 12, 1940.

See J. R. M. Butler, *Lord Lothian, 1882–1940* (1960). (H. G. N.)

LOTHIAN, known in medieval literature as *Lyonnesse*, was a primitive province of Scotland lying between the rivers Tweed and Forth. The name is of Welsh origin but of uncertain meaning and is now used in the names of the counties East, Mid- and West Lothian. Occupied in late Roman times by the Votadini, who figure in the title of the Welsh poem *Y Gododdin* (c. 600), it seems that Tweeddale, Teviotdale and the Merse (southern Lothian) had passed into Anglian hands by c. 625. If Eten is Edinburgh, Anglian control of northern Lothian, or Lothian proper, was probably won after the siege of Eten in 638, recorded in Irish annals. In 680 there was an Anglian reeve at Dunbar, and about the same time the monastery at Abercorn became an Anglian episcopal see. Angle and Pict, separated approximately by the line of the Antonine wall, were at peace for a century after c. 740.

The first king of Picts and Scots, Kenneth MacAlpin (c. 843–858), is said to have invaded England (which would have included Lothian) six times, and burned Dunbar and Melrose, while by the late 9th century the Scots were crossing the Tweed to attack Northumbria. Probably under Scottish and Viking attacks the religious life at Tynninghame, Coldingham and Melrose died, while political control by the isolated English ealdorman at Bamborough is unlikely to have been effective. Oppidum Eden (probably Edinburgh) was finally taken by the Scots c. 960. Lothian was ceded to the Scottish king c. 975 and so remained except perhaps for the decade after 1006. It was for long "in England," a benefice held by the Scottish king of the English king, and this juridical distinction was lost sight of only in the 12th century. Lothian was ceded by Edward Balliol to Edward III of England in 1333 and it was recovered only slowly by the Scots. Roxburgh fell in 1460, but Berwick has remained in English hands since 1482. For some years before he became king in 1124, David I ruled southern Lothian and founded there the abbey of Selkirk (later moved to Kelso). The infiltration of Anglo-French families, like monastic colonization, proceeded apace in his reign. Cospatrick, son of William I's earl of Northumbria, who had fled to Scotland and received Dunbar from Malcolm III, was prominent in Lothian in David's reign, and once styled himself earl. He was probably the *summus dux Laodonensium* ("chief leader of the men of Lothian") who was killed fighting for David at the battle of the Standard (1138). His descendants in the 12th century were styled earls of Lothian but in the 13th century limited their title to earls of Dunbar.

In the later 12th century sheriffs are found at Edinburgh, Linlithgow and Haddington, their baileries corresponding to Mid-, West and East Lothian. By 1263 the sheriff of Edinburgh controlled all three with constables as his deputies in Linlithgow and Haddington. These constabularies were effectively sheriffdoms by the mid-15th century, and this status was restored to Linlithgow by 1468, but not to Haddington till after 1689. The present county names date from the 19th century. See **SCOTLAND: History**.

LOTI, PIERRE (real name **LOUIS MARIE JULIEN VIAUD**) (1850–1923), French writer. His career of naval officer, taking him repeatedly to the middle and far east, provided him with the exotic décor of his novels and reminiscences—an exoticism which was to the taste of the period and made his works successful. He was born at Rochefort on Jan. 14, 1850. In 1867 he entered the naval school and in 1869 joined the training ship "Jean-Bart"; he was promoted ship's lieutenant in 1881 and during 1885–91 saw service in Chinese waters. His subsequent promotions were to

frigate captain in 1898 and ship's captain in 1906. He retired in 1910, but, mobilized in 1914, filled various administrative posts with the army. After the publication of his first novel, *Aziyade* (1879), he rapidly developed a parallel literary career. Novel followed novel, and he won the respect of the critics as well as the devotion of a large public. With such successful novels as *Pêcheur d'Islande* (1886) and *Madame Chrysanthe* (1887) to his credit, and with the approval of such exacting critics as Ferdinand Brunetière, Anatole France, Paul Bourget and Jules Lemaître, the way was made smooth for his reception into the Académie Française in 1891. Each year there was a new book, sometimes a novel—*Ramuntcho*, 1897; *Les Désenchantées*, 1906—often treating objectively the love affairs with which he tried to satisfy his dreams and melancholy at every landfall; sometimes a volume in which he himself figured—*Le Roman d'un enfant*, 1890; *Prima Jeunesse*, 1919; *Un Jeune Officier pauvre*, 1923—which reflect most fully his passionate nature and anguish for all that will never return. He died at Hendaye on June 10, 1923.

It would be unjust to dismiss Loti for his exoticism or his rather naïve celebration of primitive and pagan love. An exceptionally gifted observer, he was able to return from his voyages with a rich store of pictorial images and embody them in simple, musical prose. But this literary impressionism served a deeper strain in his nature; death, as much as love, lies at the heart of his work, and a profound despair at the passing of sensuous life is woven into his word painting. This despair was tempered by his tenderness and compassion for the human condition, and such books as *Le Livre de la pitié et de la mort* (1890) or *Reflets sur la sombre route* (1899) are perfect examples of his candid art—an art so simple that Lemaître asserted that it was impossible to discover "how it was done." His neglect by succeeding generations was the more undeserved because he was in fact a precursor and should have his place among those who experienced and diagnosed the questionings and obsessions of modern man: the longing to escape the refusal of constraint; the appeal of the irrational, the unknown and the primitive; and the emphasis on "eroticism," i.e., the value placed upon physical instinct as a challenge to death.

LOTICIUS, PETRUS SECUNDUS (1528–1560), is often considered Germany's best neo-Latin poet. Born at Niederrhein near Schlüchtern on Nov. 2, 1528, he was trained as a poet by J. Micellus, took part in the Protestant defense of Magdeburg (1547), studied for eight years at Montpellier and Padua and was professor of medicine and botany at Heidelberg from 1557 to his death there on Nov. 7, 1560. His verses are indebted to Catullus and Ovid, but his feeling for the countryside and the autobiographical directness of his love lyrics reveal a 16th-century sensibility. Though he wrote in Latin, he had evidently much in common with his great contemporary, Ronsard.

See G. Ellinger, *Geschichte der neulateinischen Poesie Deutschlands* (R. R. Bo.) vol. 2 (1929).

LOT RIVER, in southwestern France, about 300 mi. long, is a tributary of the Garonne. Rising in the Cevennes on the Mont du Goulet at nearly 5,000 ft., it flows west from Mende in a deep gorge between the limestone plateaus of the Causses de Sauveterre and du Comtal to the south and the crystalline and volcanic plateau of Aubrac to the north. At Entraygues its tributary, the Ceze, from the northeast, its most important tributary, Truyère, which in its upper course is dammed for generating hydroelectric power. Below Entraygues the Lot flows west by the small coal field of Décazeville (*département* of Aveyron) to enter the lower limestone plateaus of the Causses du Quercy. The valley opens as it continues past Cahors, a cathedral city and the old capital of Quercy, and the medieval planned town of Ville-neuve-sur-Lot to the Garonne near Aiguillon, midway between Marmande and Agen.

LÖTSCHEN PASS, an easy glacier pass (8,825 ft.) leading from Kandersteg (Bernese Oberland) to the Lötschen valley

(Valais), Switz. It is first mentioned in 1352, but was probably crossed earlier by the people of the Valais, who colonized various parts of the Bernese Oberland.

In 1384 and in 1419 battles were fought on it between the Bernese and the Valaisans, while in 1698 a mule path (of which traces still exist) was constructed on the Bernese slope, though not continued beyond. The railway between Bern and Brig (part of the Simplon tunnel route) runs beneath the pass through the Lötschberg tunnel (9 mi. long and built in 1906-12). The tunnel starts above Kandersteg and enters the Lötschen valley at Goppenstein. This pass is to be distinguished from the Lötschen-lücke (10,456 ft.), another glacier pass which leads from the head of the Lötschen valley to the Great Aletsch glacier.

(A. F. A. M.)

LOTTERY, a scheme for the distribution of prizes to be determined by chance, was reputedly an invention of the Romans. In its usual form, tickets are sold bearing different numbers. Duplicates are placed in a drum or wheel from which winning numbers are drawn on a specified date.

Although the Roman emperors Nero and Augustus used lotteries to distribute slaves, houses or ships as prizes, the chances were free. Lotteries in the modern sense originated in Italy during the middle ages spreading to France, Germany and Austria where rulers used them to raise revenue.

France first used lotteries as state revenue measures in 1539 although they had been permitted there under the name of *blanques* in 1520 by edict of Francis I.

England.—The first English lottery was drawn in 1569. In 1612 the Virginia company's expedition was partly financed by a lottery; and others were used to raise money for commercial purposes, such as the supply of water to the metropolis, the construction of Westminster bridge and the building of the British museum. However lotteries encouraged mass gambling and fraudulent drawings and, after they had been attacked by W. Wilberforce, Sir Samuel Romilly and others, parliament provided for their discontinuance in 1823. Thereafter large-scale lotteries contrived to inhibit prosecution by giving large sums to charities.

A century later, following agitation for legalized lotteries, the Betting and Lotteries act, 1934, adopted the recommendations of a royal commission and continued the prohibition on all lotteries in Great Britain, though this was subject to certain exemptions. Small lotteries incidental to bazaars, sales of work, fêtes and other entertainments of a similar character, whether limited to one day or extending over two or more days, were exempted, subject to compliance with certain conditions. So also were private lotteries that are promoted for, and in which the sales of tickets or chances is confined to, either members of one society established and conducted for purposes not connected with gaming, wagering or lotteries, or persons all of whom work or reside on the same premises.

The restrictions were further relaxed by the Small Lotteries and Gaming act, 1956, which authorized the conduct of small lotteries for other than private gain by societies for raising money for charitable, sporting and other purposes.

The Betting and Gaming act, 1960, relaxed the law still further in the case of the provision of amusements with prizes at certain noncommercial and commercial entertainments. It also amended the reference to small lotteries in the act of 1934 by inserting after the word "fêtes" the words "dinners, dances, sporting or athletic events." The act of 1960 also exempted games played by means of amusement machines, subject to compliance with certain conditions.

United States.—American colonial lotteries on the English pattern were used to raise money for public improvements and to assist in the financing of colleges including Columbia, Harvard, Dartmouth and Williams. In 1762 the Pennsylvania Provincial assembly denounced lotteries, declaring they were responsible for vice and idleness and were injurious to trade. Following the Revolutionary War lotteries flourished throughout the nation. Abuses including fraud were commonplace. Various state legislative committees recommended their abolishment. In 1833 legislation enacted in Massachusetts, New York and Pennsylvania outlawed

lotteries, and early in 1834 similar action was taken by Ohio, Vermont, Maine, New Jersey, New Hampshire and Illinois. Provisions prohibiting legislatures from authorizing lotteries in the future were inserted in many state constitutions.

Following the Civil War the Louisiana Lottery company obtained from the state legislature a 25-year charter effective Jan. 1, 1869. Its ostensible purpose was to raise money for the New Orleans Charity hospital. The lottery company became tremendously wealthy, politically powerful and corrupt. Pres. Benjamin Harrison, in a special message on July 30, 1890, to the U.S. senate and house of representatives declared: "The people of all the states are debauched and defrauded . . . by the Louisiana Lottery." He recommended that "severe and effectual legislation . . . be promptly enacted to enable the Post Office Department to purge the mail of all letters, newspapers, and circulars relating to the business." Congress responded by enacting legislation making it a federal crime to deposit lottery matter in the United States mails. In the Louisiana election of 1892, the lottery was the sole issue in the governor's contest. The antilottery candidate won and the lottery was outlawed.

Since that time lotteries were illegal in the United States until 1963, when New Hampshire passed the first sweepstakes lottery law of the century. In a few states bingo (*q.v.*), a form of lottery, is permitted when conducted by specified religious or fraternal organizations for charity.

Policy.—This form of lottery flourishes among Negroes in urban areas. Pellets numbered 1 to 78 are deposited in a drum-shaped wheel, and players wager that certain numbers will appear among twelve that are selected at the drawing. A bet that three particular numbers will be selected is known as a gig, four numbers a horse and five numbers a jack. Odds against the players are enormous.

Bolita.—A lottery similar to policy is bolita, played in Puerto Rico, and in the United States among Cuban and Puerto Rican groups. In this lottery, numbered balls from 1 to 100 are placed in a canvas sack. A small tear is made in the sack and the drawer inserts his hand and grasps one of the numbered balls. The sack is then split open and the remaining balls allowed to fall out. Although the odds are actually 99 to 1, the winning number usually pays only 70 for 1.

Numbers Game.—This game differs from policy largely in the method of selecting the winning numbers. Numbers game winners are determined from specified digits in such publicized figures as bank clearances, U.S. Treasury balances or pari-mutuel payoffs in designated races.

National and State Lotteries.—In Great Britain a proposal in 1917 to assist the financing of World War I by the issue of "premium bonds" was rejected on the recommendation of a parliamentary committee; on Nov. 1, 1956, however, premium bonds (in units of £1) were adopted to supplement the waning National Savings scheme, and from Aug. 1, 1960, each £100,000 of the monthly prize fund has been divided into 1 prize of £5,000, 10 of £1,000, 10 of £500, and about 3,000 of progressively smaller sums down to £25.

France, Spain, Italy, the Republic of Ireland (the sweepstakes for the Irish hospitals) and some South American republics have state lotteries—all with a problematic effect on direct taxation, which ostensibly they relieve. Following World War II, Russia used a lottery scheme to sell bonds for financing economic development; nonwinners received no interest on their bonds, while winners received prizes. The real home of the state lottery, however, is Australia, where, with the exception of South Australia, lotteries are conducted under government sponsorship for financing public purposes, the total revenue from ticket sales in any year exceeding £20,000,000.

The oldest lottery in Australia is Tattersall's, established in Sydney (New South Wales) by the licensee of Tattersall's hotel in 1881 and moved to Brisbane (Queensland) when the New South Wales government outlawed lotteries in 1893. In 1895 Queensland followed suit and Tattersall's moved to Hobart (Tasmania), welcomed by a government on the verge of bankruptcy. When the federal parliament was established in 1902, Tattersall's was denied

the use of the mails, but defeated the ban (which was revoked in 1930) by a great variety of ruses. Its transfer to Melbourne (Victoria) in 1954 raised a storm of protest in Tasmania, which, however, partially repaired its fortunes by licensing a new lottery that began operations in 1955. Queensland's "Golden Casket" lottery (1916) was Tattersall's first serious rival.

New South Wales had lotteries as early as 1849, and although attempts were made to outlaw them from 1893 to 1930, it found that too much money was flowing to lottery-minded states, and therefore established what is now the biggest state lottery in Australia, selling more than 1,000,000 tickets a week. New South Wales also raffles houses, cars, etc., on a scale unequaled anywhere in the world.

Western Australia's lotteries are called "charities consultations" and give their profits to hospitals (thus relieving the government of part of the charge). New Zealand adopted the state sponsored lottery, profits going to charitable purposes, when it found too much money was going to Australian lotteries.

LOTTO, LORENZO (c. 1480–1556), Italian painter, was born in Venice, but in the earlier years of his life lived at Treviso and always remained somewhat apart from the main Venetian tradition. His earliest dated pictures, the "Madonna and St. Peter Martyr" (1503) and the "Portrait of Bishop de' Rossi" (1505), both in Naples, together with its allegorical cover, now in Washington, D.C., have unmistakable *quattrocento* traits in the treatment of the drapery and landscape and the cool tonality. To his early period belong the "Assumption of the Virgin," at Asolo, and "St. Jerome in the Wilderness" (1506) at the Louvre; the altarpiece at Sta. Cristina near Treviso (1507); the Recanati polyptych and "Madonna and Saints" (1508), at the Villa Borghese; and "Marriage of Catherine," at Munich.

Lotto was in Rome between 1508 and 1512, when Raphael was painting the Stanza della Segnatura. A document in the Corsini library mentions that Lotto received 100 ducats as an advance payment for fresco work in the upper floor of the Vatican, but there is no evidence that this work was ever executed. In the next dated works, the "Entombment" (1512) at Jesi and the "Transfiguration," "St. James" and "St. Vincent" at Recanati, Lotto has abandoned the dryness and cool colour of his earlier style, and adopted a fluid method and a blonde, joyful colouring.

In 1513 Lotto was living in Bergamo, where he had entered into a contract for 500 gold ducats to paint an altarpiece for S. Stefano, completed in 1516 and now at S. Bartolommeo.

From the next years, spent mostly at Bergamo, date the London portrait of the della Torre brothers (1515); the "Susanna and the Elders" (1517) in the Contini collection, Florence; the Dresden "Madonna" (1518); the London portrait of the Prothonotary Giuliani (c. 1520) and the "Madonna and Two Saints" (1521); the Madrid "Bride and Bridegroom" (1523); the Berlin "Christ Taking Leave of His Mother" (1521) and the "Youth Against a Red Curtain" (c. 1525); the "Young Man in His Study" (c. 1524) at the Venice academy; numerous altarpieces in and near Bergamo, together with the fine series of frescoes in the Oratorio Suardi at Trescore, near Bergamo (1524), and the remarkable designs for the inlaid choir stalls in Sta. Maria Maggiore.

In 1526 or 1527 Lotto returned to Venice, where Titian ruled supreme in the world of art; and it was only natural that the example of the great master should have fired him to emulation. However, it was only a passing phase; even in the Carmine altarpiece of "St. Nicholas of Bari" (1529), which is his nearest ap-

proach to Titian, he retained his individualized, as opposed to Titian's generalized, expression of emotion. From the Venetian years 1526 to 1529 date the portraits "Andrea Odoni" at Hampton Court and "Bishop Tommaso Negri" at Split (both 1527); the so-called "Lucretia" at London, the "Man on a Terrace" at Cleveland and the "Man Holding a Claw" at Vienna (all c. 1527); the Recanati "Annunciation" and the Brescia "Adoration of the Shepherds" (c. 1528); and the strangely misnamed "Triumph of Chastity" at the Rospigliosi palace in Rome.

Among pictures executed between 1529 and 1540, chiefly in the Marches, are the Louvre "Christ and the Adulteress" (c. 1530); the "Youth Against a Green Curtain" (c. 1530) and the "St. Sebastian" and "St. Christopher" (1531) at Berlin; the "Crucifixion" (1531) at Monte San Giusto; the "Visitation" (c. 1530) and the "St. Lucy Altarpiece" (1532) at Jesi; the Bergamo "Holy Family and Catherine" (1533); male portraits at Villa Borghese (c. 1530) and Palazzo Doria (c. 1535) in Rome; the Uffizi "Madonna and Saints" (1534); and the monumental Cingoli "Madonna of the Rosary" (1539).

Between 1540 and 1548 Lotto was in Venice and Treviso and was once more influenced by Titian. Works of these years include the "St. Antonino Giving Alms" (1542), in SS. Giovanni e Paolo, and the "Madonna and Saints" (1546) in San Giacomo dell'Orto at Venice; the portraits of "Messer Febo da Brescia" and of "Madonna Laura da Pola" (1544) as well as the "Pietà" and the "Portrait of an Old Man" all in the Brera at Milan; the "Madonna and Saints" (c. 1546) in Sta. Maria della Piazza at Ancona; the "Family Group" (1547) in London; and the "Madonna in Glory" (1548) at Mogliano.

In 1549 Lotto went once again to the Marches where he painted the "Assumption" now in the Ancona museum. In 1550 he lost his voice and partly his eyesight. In 1554 he made over all his belongings to the Holy House at Loreto and began one of his most sensitive masterpieces, the "Presentation in the Temple," which remained unfinished at his death in the autumn of 1556.

LOTTO: see BINGO.

LOTUKO (LATUKA, LOATUKO), a Nilo-Hamitic people of southern Sudan, living near Torit; they numbered about 30,000 in the 1960s and there were an additional 30,000 Lotuko-speaking people divided into many small, independent subtribes. Lotuko are agricultural and grow millet, maize, peanuts and tobacco; they also have many cattle. They are remarkable for their large, fortified villages, often with several hundred huts and divided into named quarters. They lack a centralized chieftaincy but recognize the rule of hereditary rainmakers, each of whom has ritual and political authority over one of the nine rain areas. There is also a number of exogamous, patrilineal, totemic clans with a distribution that is distinct from that of rain areas.

The rainmakers control an elaborate age-set system. There are annual initiation rites for males who have reached puberty; four such annual groups are together initiated into sets based upon a village; when this is completed all members are initiated into wider sets on a rain-area basis; every 16 years there is a last initiation that involves the lighting of a new fire by incun. Hereditary diviners who can counter witchcraft have considerable power. Lotuko believe in a supreme being, Naijok. See also AFRICA: *Ethnography (Anthropology)*: *Northeast Africa and East Africa*; EQUATORIA; NILO-HAMITES.

LOTUS, a popular name applied to several different plants. The lotus fruits of the Greeks belonged to *Zizyphus lotus*, a bush native in south Europe. It has large fruits containing a meaty substance that can be used for making bread and fermented drink. In ancient times the fruits were an article of food among the poor. A wine made from the fruit was thought to produce contentment and forgetfulness (hence the "Lotophagi" or lotus-eaters). *Zizyphus* is a member of the buckthorn family (Rhamnaceae).

The Egyptian lotus is a white water lily, *Nymphaea lotus*, as are the sacred lotus of the Hindus, *Nelumbium nelumbo*, and the American lotus, *N. pentapetalum* (or *Nelumbo luteum*). The lotus tree, known to the Romans as the Libyan lotus, was probably *Celtis australis*, the nettle tree (*q.v.*), a southern European tree, a member of the elm family, with fruits like small cherries, first red and then black.

The *Lotus* of botanists is a genus of the pea family (*Leguminosae*), containing a large number of species of herbs and undershrubs widely distributed in the temperate regions of the old world. It is represented in Britain by *L. corniculatus*, bird's-foot trefoil, a low-growing herb, common in pastures and waste places, with clusters of small bright yellow pealike flowers, which are often streaked with crimson; the popular name is derived from the pods, which when ripe spread like the toes of a bird's foot.

Lotus in Decoration.—The lotus, through gradual conventionalization, became one of the most prolific ornamental forms. The flower itself is represented as a common votive offering and was frequently painted as though tied on to shrines or house pillars. The conventionalized form used in decorating the capitals (*q.v.*) of columns—the lotus bud capital and the late lotus flower capital—also served in various ways as a basis for borders and all-over patterns. Two stylized varieties, the trilobe or three-leaved lotus and the lotus palmette (in which the flower is combined with a semicircle or semiellipse of radiating petals above it), were largely used by the Assyrians and all the peoples along the eastern shore of the Mediterranean. Thus the lotus is at the basis of such varying forms as the Assyrian sacred tree and those Phoenician stele capitals which were the parents of the Ionic order.

Lotus flower bud and palmette forms are also the origin of a great number of Greek, painted ceramic patterns and from them evolved into the eggs and dart and into the anthemion (*q.v.*). The Romans not only borrowed and modified these Greek lotus derivatives but also received further lotus forms from Etruscan art. Lotus derivatives, like many other Roman decorative motives, appear in modified form throughout Byzantine and Romanesque art. Lotus forms or derivatives are common even in the 20th century; thus their influence can be traced continuously back from modern times, through the Renaissance, medieval, Roman, Greek and western Asiatic work to its source in Egypt at least 5,000 years ago.

(T. F. H.)

Lotus as a Symbol.—The earliest attested use of the lotus as a symbol is doubtless in Egypt, but it is symbolically important throughout the greater part of Asia, particularly in countries of Hindu and Buddhist obedience. Fundamentally the lotus symbolizes fertility, and its other meanings seem to stem from this aspect. Hence, the lotus as a seat for divinities emphasizes their generative force. In India, for example, the lotus is identified with Lakshmi, the wife of Vishnu and a form of the Mother Goddess, associated with prosperity. In Buddhism the lotus throne stands for purity and divine birth. Like the lotus, which germinates under the water and arises to the surface to unfold, so too the Buddha is born in the impure world but through his enlightenment rises above it. In Egypt divinized dead were believed to be reborn from lotus flowers, henceforth belonging to the world of the gods. Tantric Buddhism emphasizes a sexual symbolism; the lotus stands for the feminine, hence generative, principle through which, in union with the masculine principle represented by the thunderbolt (*vajra*), the phenomenal world comes into being. The ancient notion of fertility persists in Japan, where eating the lotus flower or stalk is popularly thought to promote human fecundity.

The lotus also symbolizes the sun. In Egypt it stood for Horus as ruler of the sky. Hiding its flower at night and opening with the first morning rays, the lotus naturally suggested itself as a symbol for Nerfertem, the god who personified the rising sun and who supposedly emerged from a lotus every morning and retired into it every night. In Buddhism the fully open lotus preserves a strong solar character, its leaves being obviously identifiable with the rays of the sun, its stem being a kind of sacred cosmic pivot.

(E. D. S.)

LOTUS-EATERS (*LOTOPHAGI*), a people encountered by Odysseus in the journey recounted in the *Odyssey*. They lived on a plant called *lotos*, which they offered to Odysseus' men. Those who ate of it forgot home and friends and wanted only to remain there and eat of that food.

It should be plain enough that the lotus-eaters and their country are situated in fairyland, but in addition to interpreting the story allegorically, many ancient scholars amused themselves by trying to identify them with some people of northern Africa, since that continent produces one or two edible plants called *lotos* by the Greeks. This foolishness has been imitated by some moderns.

The phrase "to eat lotus" is used metaphorically by numerous ancient writers to mean "to forget," "to be unmindful."

See HOMER; ODYSSEUS.

LOTZE, RUDOLF HERMANN (1817-1881), German philosopher who bridged the gap between classical German philosophy and 20th-century idealism, was born at Bautzen, on May 21, 1817, the son of a physician. After studies in the *Gymnasium* of Zittau he entered the University of Leipzig in 1834. Four years later he gained doctorates of philosophy and of medicine.

Lotze's studies were governed by two distinct interests. The first was scientific, based upon mathematical and physical studies under the guidance of E. H. Weber, W. Volckmann and G. T. Fechner. The second was his aesthetical and artistic interest, which was developed under C. H. Weisse. His vocation then seemed to be the reconciliation of science with art, literature and religion; and hence the central point of his philosophy has been described as an analysis of the concept of the mechanism of nature with the object of proving that this concept necessarily leads to the assumption of an ideal principle of existence. While a lecturer at Leipzig he published two short works, his *Metaphysik* (1841) and his *Logik* (1843), which laid the foundation of his system. In 1844 he was appointed professor of philosophy at Göttingen, where he remained until 1881. During this period he produced his most important works.

The first of Lotze's works to attract attention were articles contributed to Rudolf Wagner's *Handwörterbuch der Physiologie* in which Lotze combated the then current vitalistic theories. He first became generally known through his *Allgemeine Pathologie und Therapie als mechanische Naturwissenschaften* (1842; 2nd ed., 1848). To the same period belong his more systematic *Allgemeine Physiologie des körperlichen Lebens* (1851) and his *Medizinische Psychologie oder Physiologie der Seele* (1852). Notwithstanding the idealistic position adopted in his earlier works, his polemic against vitalistic theories led him to be regarded as a materialist, and to correct this misinterpretation he published his *Streitschriften* (1857).

In 1856 Lotze had published the first volume of his chief work, the *Mikrokosmos*, the second volume of which appeared in 1858 and the third in 1864. This contained a comprehensive account of his philosophical views. In 1868 he published his *Geschichte der Aesthetik in Deutschland*. He then planned to set out in three further volumes a more systematic account of his philosophy as a whole. The first of these, *Logik*, appeared in 1874 (2nd ed., 1880), the second, *Metaphysik*, in 1879. The third, dealing with practical philosophy, art and religion, was uncompleted at Lotze's death, which took place on July 1, 1881, a few months after he had moved from Göttingen to the chair of philosophy at Berlin.

Lotze belongs to the earliest phase of the transition from a conception of philosophy which claims or assumes that by deductive reasoning or reflection discoveries can be made about the nature of the universe to the view that philosophy is concerned only with the analysis and clarification of concepts. Though influenced

in his early studies by Fichte, Schelling and Hegel, Lotze came to reject the methodology of these philosophers and more especially the dialectical method of Hegel. But neither in the method nor in the content of his philosophy did he differ so widely from his predecessors as he himself believed. Though rejecting dialectical methods, he relied upon reflection to defend hypotheses concerning the nature of reality which cannot be presented as self-evident or as evidenced by scientific observation. His conclusions were in accord with the idealist tradition. He believed that all that appears to us must be conceived as a reality, the nature of which must be construed as akin to our own nature and our own mental life. He held that this ultimate reality is an infinite divine being, within which finite individuals act and live.

More distinctive were Lotze's views concerning mechanism and teleology. He opposed the prevailing doctrine that mechanical laws apply only to inorganic matter and that processes in living things are determined by final causes and vital forces. His contention was that the laws that govern particles of matter in the inorganic world governed these particles also when they were combined in a living body. But he also rejected the view still widely assumed that explanations in terms of efficient causes and explanations in terms of final causes are alternative and incompatible. He held that mechanism is the instrument of purpose—that we explain why a living thing does what it does in terms of ends and how it does what it does in mechanistic terms. (This conception of the relation of mechanism and teleology later derived support from biological studies of directed behaviour and from the work of cyberneticians, who constructed mechanisms which behave like goal-directed living things; see CYBERNETICS.) Lotze argued that God in creating and maintaining the world and in attaining his ends does so entirely through the laws disclosed by the natural sciences.

As professor of philosophy at Göttingen, where he followed Herbart and was followed by G. E. Müller, Lotze takes his place in a distinguished succession of philosophers who influenced the development of psychology as an independent science. His *Medizinische Psychologie* was the prototype of the many physiological psychologies which were to follow. His doctrine of "local signs" still receives attention from students of the theory of space perception. Retaining the doctrine of the soul, he attempted a more detailed analysis than had hitherto been attempted of the phases through which physical stimulation generates sensation and other experiences.

His interest in art and in morals and the biological approach necessary to the study of medicine combined to lead him to place special emphasis upon feeling and emotion. His contributions to the philosophy of mind and to psychology distinguish him both from the rationalist philosophers and from the intellectualist, sensationist and associationist psychologists. His influence was to be reinforced by other developments in biology, notably the Darwinian theory of evolution.

Lotze's influence upon the development of experimental psychology was mainly through his pupils and disciples such as C. Stumpf and G. E. Müller. His psychological doctrines were interpreted by James Ward in Great Britain and by George T. Ladd in the United States. Each occupied in his own country a position similar to that of Lotze in Germany, and both played a significant part in the transition of psychology from being a philosophy of mind to being the study of its natural history.

BIBLIOGRAPHY.—There are English translations of Lotze's work by E. E. C. Jones, *Microcosmus*, 2 vol. (1885), and by B. Bosanquet, *Lotze's System of Philosophy*, 4 vol. (1887-88). LOUBET, ÉMILE FRANÇOIS (1838-1929), 7th president of the French republic, was born on Dec. 31, 1838, the son of a farmer at Marsanne (Drôme). He practised at the Paris bar

and in the crisis of 1870 backed Léon Gambetta's policy. He entered the chamber of deputies in 1876 and worked for the republican cause, especially for education, attacking the clerical system established by the *loi Falloux*, and working for the establishment of free, obligatory and secular primary instruction. Loubet entered the senate in 1885 and became minister of public works in the Tirard ministry (Dec. 1887-March 1888).

Forming his own ministry on Feb. 28, 1892, Loubet held the office of minister of the interior as well as the premiership, and so had to deal with the anarchist outrages and strikes of that year. His ministry fell in November over the Panama scandal, but for a short time Loubet continued to serve as minister of the interior under Alexandre Ribot. In 1896 he became president of the senate, in Feb. 1899 president of the republic.

Loubet's presidency was marked by three major crises. In June 1899 he summoned René Waldeck-Rousseau to form a ministry to settle the Dreyfus case and appealed to republicans of all shades to rally behind it. (See DREYFUS, ALFRED.) Acting on the advice of Gen. Gaston Galliffet, minister of war, Loubet eventually remitted the sentence passed on Dreyfus at Rennes. Secondly, friction between France and the Vatican intensified after Pius X became pope (Aug. 1903). It reached its height in March 1904 when Pius protested against Loubet's official visit to the king of Italy in Rome. Under Émile Combes anticlericalist policies triumphed, and in 1905 church and state were separated amid violent controversy.

International tensions also reached their height, but frictions with Great Britain were satisfactorily ended by the Anglo-French entente of 1904. Loubet's tough peasant qualities, combined with a genial simplicity and an unaffected dignity, enabled him to fulfill with success one of the most exacting presidencies of the third republic. After his term of office ended in Feb. 1906 he retired to private life, and died at Montélimar on Dec. 20, 1929.

See A. Combarieu, *Sept ans à l'Élysée avec le Président Émile Loubet* (1932). (D. TR.)

LOUD-SPEAKER (SPEAKER), a device for converting electrical into acoustical signal energy that is radiated into a room or open air. The term "signal energy" indicates that the electrical energy has a specific form such as that corresponding to a speech or music signal. The speaker should preserve the essential character of this signal energy in converting the energy from electrical to acoustical form. This definition of a loud-speaker excludes such devices as buzzers, gongs, sirens and the like in which the acoustical signal does not correspond in form to the electrical signal. The part of the speaker that converts electrical into mechanical energy is frequently called the motor. The motor vibrates an element called the diaphragm that in turn vibrates the air in immediate contact with it. This vibration results in slight pressure changes in the air above and below atmospheric pressure. These pressure changes are transmitted into the room or open air as a sound wave (see SOUND).

Kinds.—Speakers are conveniently classified by the kind of motor employed to convert the electrical into mechanical energy. Common types are the moving coil or "dynamic," and the magnetic armature or "magnetic." Less common are the piezoelectric or crystal, and electrostatic or condenser types. The moving-coil and magnetic-armature types are both technically defined as magneto-dynamic types because the mechanical forces result from the interaction of a steady magnetic field and a magnetic field produced by the electrical current. In the moving-coil motor the signal current passes through a coiled conductor and produces a varying magnetic field that interacts with a steady field. This interaction results in a force that moves the coil, which in turn moves the attached diaphragm. The strength or magnitude of the force is proportional to the strength of the current. In the magnetic-armature type the signal current passes through a fixed coil that induces a magnetic field in a movable element of magnetic material called the armature. Speakers using the latter motor are popularly called "magnetic." Those using moving-coil motors, particularly when they are of the large direct-acting diaphragm type, are popularly called "dynamic." The fixed magnetic field required by magnetic speakers may be supplied by a permanent magnet or by an electro-

magnet. The term "electrodynamic" is said to have been applied originally to early commercial versions of moving-coil speakers. The prefix "electro" had no bearing on the source of the fixed or steady magnetic field supplied by either electromagnets or permanent magnets.

In piezoelectric or crystal speakers the force produced by a crystal having piezoelectric properties moves the diaphragm. In electrostatic or condenser speakers a very light conducting diaphragm is used as one electrode of a condenser or capacitor and is suspended so that it vibrates freely. The fixed electrode (or electrodes) is closely spaced from the moving one. Both of these types have had limited application because of their relatively low conversion efficiency and power output limitations at low frequencies.

Alternatively speakers are classified as horn, and hornless or direct-radiator types. A horn speaker has a horn attached to a relatively small diaphragm. The large or mouth end of the horn behaves as a large lightweight diaphragm that radiates sound more efficiently than the small diaphragm. The horn proportions, including the rate of area expansion or flare, are selected to give the desired compromise between efficiency, frequency response, directional properties and size. To reproduce low frequencies the rate of expansion or flare must be small, necessitating a long horn, and the mouth must be large. Low-frequency horns are therefore large. High-frequency horns are small and are often used as the high-frequency speakers in multispeaker systems. Horn speakers may be made quite efficient. They are therefore primarily used where efficiency and high acoustic power output are important and size less important.

In the direct-radiator or hornless speakers the diaphragm is made large enough to radiate directly into unconfined air. To prevent the low-frequency front and back waves from interfering or neutralizing each other, a rigid surface or baffle must be interposed as an extension of the diaphragm support. This extension may take the form of an open-back box or cabinet, a totally enclosed box, a box closed except for a vent or port, or a conduit or duct which may be folded. The open cabinet is commonly employed in radio and television receivers. The closed box is lined with sound-absorbing material and is used when the radiation from an open back is objectionable. The closed box tends to give more uniform low-frequency response and is less influenced by proximity to a room wall but sacrifices some efficiency. The vented enclosure augments a portion of the low-frequency range. The "boomy" or excessively resonant low-frequency response present in some types arises primarily from the use of too small an enclosure and a speaker with excessive diaphragm support stiffness.

Development.—Historically the horn-type speaker first attained commercial success. The electrical signals generated by early radio receivers were very feeble, and a telephone receiver had to be held to the ear to obtain an audible signal. Because of their relatively widespread introduction in World War I, vacuum tubes or valves were rapidly incorporated in the radio set design of the postwar era. This practice made available the much greater electrical signal energy required to operate a speaker. Many early speakers consisted of a telephone receiver, sometimes slightly modified to accept the greater signal energy, to which a horn was attached. The horn improved the efficiency of the electrical-to-acoustical energy conversion process although at the expense of naturalness of reproduction. The need for greater electrical energy for speakers led to the development of more powerful tubes and these in turn permitted the use of less efficient but more natural sounding speakers. Magnetic-armature speakers employing large-area conical paper or cloth diaphragms were followed by the moving-coil or "dynamic" types employing moderate-size conical paper diaphragms. The latter are used almost universally in radio and television receivers because of their low cost, simple construction, frequency range and small size even when designed to reproduce relatively low frequencies. Their major disadvantage is low efficiency but this became of relatively little importance in view of the ease with which adequate signal energy could be obtained in receivers or amplifiers operated from external power sources.

Design Problems.—The major speaker-design problems arise

from the frequency range to be produced and the need for attaining adequate efficiency. Other factors such as uniformity of response with frequency, uniform directivity or spatial distribution of the emitted sound, linearity or proportionality of the acoustic output and electrical input over the necessary signal-intensity range must also be considered. An ideal speaker would be capable of faithfully reproducing at least any sound the human ear can hear. This range involves sound intensities differing by a factor of more than 10,000,000,000,000, frequencies from about 20 to 20,000 cycles per second and sounds varying rapidly in character. In practice these difficult requirements are modified by the limitations of the associated sound-reproducing system, by the infrequent occurrence and relative unimportance of certain sounds and by the tolerance or charitability of the ear. Background noise at the microphone and at the listener's location and electrical disturbances in the signal-transmission system limit the minimum speaker signal intensity that can be heard. The intensity of the louder common speech and music sounds is substantially below the maximum intensity the ear will tolerate without pain. These factors reduce the ratio of maximum to minimum intensity required of a complete sound-reproducing system, including speaker, to approximately 1,000,000 to 1—an attainable but not commonly realized value. These numerical values are large but psychological tests have shown that over much of the useful intensity range the intensity has to be increased by a factor of from five to ten for the listener to judge that the loudness has doubled. The ideal frequency range required of the speaker is also reduced by the noise that obscures or masks the very high and very low frequencies, which are difficult to hear. The infrequent occurrence of these extreme frequencies also reduces their importance. Consequently even a range from 40 to 15,000 cycles is useful primarily in experimental and controlled studio reproduction. A range from 80 to 8,000 cycles in an otherwise distortion-free system is capable of giving very realistic and emotionally satisfying reproduction.

The speaker should treat all frequencies alike. This requirement means uniform electrical-signal-to-sound conversion efficiency at all frequencies—a goal difficult to attain in a single speaker. In a high-quality speaker the change in efficiency with frequency will occur gradually and compensation may be provided for this in the electrical system. The speaker should also treat all frequencies alike for all listener locations. This requirement involves the factors of distance to the listener and angle between the principal axis of the speaker and the listener location. Outdoors and in large auditoriums the speakers are directed toward the more remote listeners to attempt to maintain the intensity in their region. It is hard to radiate all frequencies equally well toward each listener location. Radiation, interference, focusing and similar space effects in the sound field depend on the relation between the diaphragm size and shape and the length of the sound wave. The length of 8,000- and 80-cycle sound waves is 1.7 and 170 in. respectively (these vary inversely with frequency), a variance which accounts in large measure for the difficulty of obtaining uniform space distribution and radiation efficiency over the broad frequency range. When the sound wave is long compared to the maximum dimension of the horn mouth or exposed diaphragm the speaker is nondirectional. When the wave is very short there tends to be marked concentration of the sound in a narrow beam. This effect is reduced by subdividing a horn into a number of small horns or cells (which accounts for their designation as "cellular horns"), by the use of acoustical lenses and by special mouth shapes involving a narrow dimension that produces less concentration. In the case of large exposed or direct-radiating diaphragms the effect is reduced by providing concentric circular diaphragm segments that help confine the diaphragm vibration to the region near the apex at high frequencies, thereby reducing the effective diaphragm size and broadening the radiated beam. More uniform space distribution and conversion efficiency are also obtained by using two or more speakers, each covering a portion of the frequency range.

The acoustical environment of the speaker influences its performance. Both direct and reflected sound reach the listener. In small rooms the reflected sound may markedly influence the speaker performance and what the listener hears. Much poor low-

frequency performance attributed to speakers actually arises because a small room has few low resonant frequencies and these are widely separated in frequency. Consequently the speaker can transmit sound energy efficiently through the room to the listener only in narrow low-frequency bands.

LOUGHBOROUGH, a municipal borough (1888) in the Loughborough parliamentary division of Leicestershire, Eng., near the Soar river and on the Loughborough canal, 11 mi. N.N.W. of Leicester by road. Pop. (1961) 38,621. There was a settlement there before the Roman invasion, but evidence of the Roman occupation is scanty. In Saxon times Loughborough was becoming a place of some size, and later reference is made to the township in Domesday Book. Grants for markets and fairs were made in the 13th century, when the wool trade was an important feature of the district. Lacemaking later became the chief industry, but when the machines of John Heathcoat (*q.v.*) were destroyed by the Luddites the industry lost much of its importance.

The town is a marketing centre in a large and fertile agricultural district, lying to the east of Charnwood forest. The town hall and corn exchange (1855) stand prominently in the market place. Loughborough's principal industries are electrical engineering, bell founding and the manufacture of hosiery, lifting machinery and pharmaceutical goods.

Loughborough is an educational centre, Loughborough College of Technology being of wide repute, while the Training college is the largest in the country for men schoolteachers; there are also colleges of further education and art. The grammar school was founded by Thomas Burton, a wool merchant, in 1495. He and the Taylors, who established the bell-founding industry, are commemorated in the parish church. The memorial for World Wars I and II is a tower, with a carillon of 47 bells, which was built by public subscription and opened in 1923.

LOUGHREA (BAILE LOCHA RIACH), a market town of County Galway, Republic of Ireland, on the northern shore of Lough Rea, 116 mi. W. of Dublin by road. Pop. (1961) 2,784. There are slight remains of an Early English Carmelite friary, dating from about 1300. Loughrea is the seat of the Roman Catholic bishop of Clonfert, and has a cathedral built in 1900–05. A part of the castle of Richard de Burgh, founder of the friary, still survives, and there are traces of the town fortifications. In the neighbourhood are a cromlech, "souterrains" (underground passages and chambers) and two ruined towers. Crannogs (*q.v.*), or prehistoric stockaded islands, have been found in the lough.

LOUIS I THE PIOUS or LE DÉBONNAIRE (778–840), Carolingian emperor from 813 to 833 (sole emperor from 814) and from 834 to 840, was the son of Charlemagne (*q.v.*) and of Hildegard. His father made him king of Aquitaine in 781, to satisfy Aquitanian separatism, but in practice retained control long after Louis had grown up. Louis, however, was allowed considerable freedom in his measures to conquer and govern Catalonia. Having first attacked Barcelona in 801, he organized a large expedition, reinforced with troops sent by his father in spring 803, and this time took the town. He also carried out Charlemagne's plans for repopulating certain areas and for establishing new monasteries in Septimania and south of the Pyrenees and kept the Gascons in subjection. From time to time he joined his father's Italian and Saxon campaigns.

In his plan of 806 for dividing his territory between his three sons, Charlemagne left all southwestern Gaul in Louis' hands. Subsequently, however, the deaths of his two brothers (in 810 and 811) made Louis the sole possible heir to the imperial dignity, and Charlemagne crowned him at Aachen in Sept. 813. Louis assumed effective power on his father's death (Jan. 814). By his wife Irmingard (Ermengarde) he had three sons, later known as the emperor Lothair I, Pepin of Aquitaine and Louis the German.

Character and Policy of Louis.—The new emperor was very different from Charlemagne. He was a thinker rather than a

warrior, and he applied the logic of his faith more consistently than any other member of the Carolingian dynasty. Unfortunately in having to succeed a personality so dominating, he was faced, moreover, with the consequences of many ill-considered judgments of his father's. Also, whereas Charlemagne had maintained order by sheer mastery, Louis sought by fair and upright dealing to enlist the co-operation of his subjects, but they mistook for weakness his anxiety to make his actions conform to the teachings of the church. For instance, the public penance which Louis imposed on himself and on his court at Attigny (822) to expiate the death of his nephew Bernard, king of Italy—whose blinding he had ordered in punishment for rebellion (818)—was regarded by contemporaries as an unwarrantable subjection of imperial to sacerdotal authority. Finally, Louis inherited from Charlemagne an ardent sensuality, which made him unduly dependent on his two successive wives.

The lay coronation of 813 was supplemented in Oct. 816 by a second ceremony, performed by Pope Stephen IV (V) at Reims. Louis was already showing that piety and preoccupation with Christian political theories which laid him open to the charge of excessive deference to the church. Even so, in his edicts of 816–817 and of 818 or 819, he forcibly imposed on the church a reform and reorganization of monasteries and dioceses that Charlemagne had never attempted. Likewise, in his *Ordinatio imperii* (817) he tried to reconcile the safeguarding of Christian order and unity with the old Frankish custom of partition and with regional separatisms within the empire. In this *Ordinatio* he planned the disposition of the empire: he would have no division of the imperial authority, which Lothair was to inherit, but he mapped out kingdoms for his other two sons. To spread Christianity he sent missions among the Scandinavians and the Slavs; and to establish contact with the latter he created the Bavarian march of Friuli.

Very few periods are more obscure and more diversely interpreted by historians than the years 825–830. Louis warned his subjects in 825 to make good their omissions in every sphere, and a thorough inquest conducted by *missi dominici* seemed to presage important reforms; but nothing further was done. It seems certain that the emperor was fully occupied in dealing with the intrigues of certain aristocratic families, some of them close to the crown. Among these were probably the relations by marriage of his sons Pepin and Lothair. The treason of Lothair's father-in-law, Hugh, count of Tours, and of Matfrid of Orléans, who had been sent to Spain with reinforcements in 827, shows that the balance established by Charlemagne between the crown and its delegate counts was shifting in the counts' favour.

The Period of Rebellions (830–840).—The empress Irmingard had died on Oct. 3, 818; and four months later Louis had married Judith of Bavaria, who in 823 bore him a son Charles (see CHARLES II the Bald). The emperor's attempts to provide this son with a patrimony were destined to provoke a series of internecine wars. At an assembly convened at Worms in 829 to deal with the problem of the counts Louis took the opportunity of endowing Charles with a kingdom carved out of the very heart of the empire. Lothair, who objected strongly, was sent off to Italy; and Bernard, previously governor of Septimania, now became Louis' chief counselor.

There followed an open struggle between the palace and a group of magnates who worked on the jealousies of Lothair and Pepin. A first revolt, in April 830, brought about the imprisonment of the empress at Poitiers, Bernard's flight and the restoration of Lothair's friends as royal counselors, but by the end of the year Louis had regained the upper hand. Judith was formally reinstated at court in Feb. 831, with the assent of her stepsons, who had abandoned their accomplices; and a fresh partition of territory was considered. By 833, however, Louis was being denounced on all sides, by prelates and exiled lay vassals alike, as having destroyed the unity of the empire which the *Ordinatio* of 817 had achieved. Lothair returned from Italy, having persuaded Pope Gregory IV to try to "convince" Louis that he should give place to an emperor better able "to maintain the unity of Christendom." The rival parties came face to face on the Lügenfeld (Field of Lies), near Colmar in Alsace (June 833). Though Louis was still

supported by many of the clergy, the presence of the pope on the side of Irmingard's sons and the defection of leading prelates constrained him to yield. Lothair made him do a humiliating penance and renounce the throne.

A year later the three victors, having partitioned the Frankish lands, were at odds among themselves. Pepin and Louis turned against Lothair, the magnates were divided, the pope withdrew his support, and monastic opinion was for Louis. Louis and Judith were back on the throne at Easter 834. Lothair was once more exiled to Italy and his supporters punished, particularly the bishops. Thereafter there was relative calm for the rest of the reign, though in his lands in the east Louis the German remained in a state of constant revolt. After Pepin's death (838), Louis was able to persuade Lothair, in 839, that Charles should have Aquitaine. Even so Louis' death on June 30, 840, was the signal for the struggle between his sons to begin anew; and even before that time the Vikings had begun to attack the empire from without.

See L. Halphen, *Charlemagne et l'empire carolingien* (1947); H. Fichtenau, *Das Karolingische Imperium* (1949). (J. DE.)

LOUIS II (822 or 824–875), Frankish emperor from 850, was the eldest son of the emperor Lothair I. Nominated in 839 by his grandfather, Louis I the Pious, to be his successor in Italy, he took over the administration there on his father's behalf in 844. Pope Sergius II crowned him king of the Lombards in Rome on June 15, 844; and Pope Leo IV crowned him emperor in Rome in April 850. From that time onward he ruled independently. When Lothair I's "Middle Realm" was divided in Sept. 855, Italy was definitely given to Louis; and after Lothair's death a few weeks later Louis was sole emperor. This dignity, however, now implied only rule over part of the Carolingian dominions, with no pre-eminence over the whole. Even so, Louis upheld his authority over Rome and kept good relations with the papacy, except for a short conflict with Nicholas I in 864 because the pope had annulled the divorce of his brother Lothair (II); and in 871 he stressed the legitimacy of his Western, truly Roman empire in a famous letter to the Byzantine emperor Basil I. Meanwhile after the death of his brother Charles in 863, he had added Provence to his dominion.

Louis II's most important task was the war against the Arabs, who raided Italy and had even surprised Rome in 846. He combined this with the old plan of the Lombard kings to extend their dominion also over the southern half of the peninsula and thus to unite all Italy. In 866 he began a great campaign which culminated, with the help of the Greek fleet, in the conquest of the Arab headquarters at Bari (Feb. 2, 871). Then, just when he seemed to be reaching his goal, Louis was made prisoner at Benevento by Duke Adelchis in Aug. 871. Though he was set free after a month and though he won another victory, near Capua in 872, his power and his energy no longer sufficed for a decisive blow against the Arabs. He gave up his hopes and withdrew to northern Italy, where he died near Brescia on Aug. 12, 875; he was buried in the church of S. Ambrose in Milan. As he had only a daughter, Irmingard, married to King Boso of Lower Burgundy, the elder male line of the Carolingian dynasty died out with him.

(T. SCH.)

LOUIS III THE BLIND (c. 880 or 882–928), Frankish emperor from 901 to 905, was a son of Boso, king of Provence or Lower Burgundy, and Irmingard, daughter of the emperor Louis II. The emperor Charles III the Fat took him under his protection on Boso's death in 887; but Louis was not recognized as king of Provence until 890, when Irmingard had secured the support of the East Frankish king Arnulf and of Pope Stephen V. In 900, he was called to Italy by a group of nobles in opposition to Berengar of Friuli: he crossed the Alps, was crowned king of the Lombards at Pavia in Oct. 900 and received the imperial crown from Pope Benedict IV at Rome in Feb. 901. He gained a temporary authority in northern Italy, but was soon compelled by Berengar to leave the country (902). In 904, however, he went again to Italy, where he secured the submission of Lombardy; but on July 21, 905, he was surprised at Verona by Berengar, who blinded him and sent him back to Provence, where he remained until his death. He married Adelaide, possibly a daughter of

Rudolf I of Upper Burgundy. His son Charles Constantine, who succeeded only to the county of Vienne, was perhaps a bastard.

LOUIS IV THE BAVARIAN (1282–1347), Holy Roman emperor—though with a controversial title—from 1328, also duke of Bavaria from 1294 and German king—as such reckoned sometimes as Louis V—from 1314, was born on April 1, 1282, probably in Munich, the second son of the Wittelsbach Louis II, duke of Upper Bavaria and count of the Rhenish Palatinate, and his consort Mechthild, daughter of the Habsburg German king Rudolf I.

The Wittelsbach Succession.—After his father's death (Feb. 2, 1294) Louis became joint ruler of Upper Bavaria and the Palatinate together with his elder brother Rudolf, though he remained in wardship till April 1, 1302. His brother, however, did not wish to share the government, and in the resultant quarrel Louis was helped by his Habsburg relatives, at whose court in Vienna he may have been educated; in the end he was granted the northwestern part of Upper Bavaria, with Ingolstadt as capital (Oct. 1, 1310). A new quarrel broke out over the wardship of the young dukes of Lower Bavaria, but this was ended by the peace of Munich (June 21, 1313), which again instituted common rulership by the two brothers. After that Louis fell out with his cousin and future rival, Frederick of Austria, who had also intervened in Lower Bavaria; Louis defeated him at Gammelsdorf, near Munich, on Nov. 9, 1313. In 1317 he made his brother resign his claims on Bavaria in return for an annual subsidy; but though Rudolf died on Aug. 13, 1319, differences between Louis and Rudolf's heirs were settled only by the compact of Pavia (Aug. 4, 1329), by which Louis granted to his nephews the Rhenish Palatinate and the Upper Palatinate (part of the northern Bavarian area, with its capital at Amberg). In 1340 when the ducal family of Lower Bavaria became extinct, Louis united Upper with Lower Bavaria.

The German Kingship.—Louis had already been a candidate for the German crown in 1308 after the assassination of King Albert I. After the death of Henry VII he was elected German king by five electors before the gates of Frankfurt on Oct. 20, 1314, thanks mainly to the support of the archbishops Baldwin of Trier and Peter Aspelt of Mainz against his rival Frederick of Austria (see **FREDERICK III**, German king). He was crowned at Aachen on Nov. 25, 1314, with false insignia by the archbishop of Mainz (who had no right to perform this ceremony). It was not until Sept. 28, 1322, that Frederick was finally defeated, in the battle of Mühldorf. Frederick was then imprisoned for three years in Trausnitz castle (in the Upper Palatinate), but even so Louis had to continue fighting against Frederick's brother Leopold till 1326. The plan whereby the two kings were to rule jointly did not prove feasible, and Frederick eventually limited himself to ruling Austria.

The Emperor and the Papacy.—After his victory at Mühldorf, Louis considered himself the rightful German king, with a consequent claim to the imperial dignity; and in 1323 he sent his marshal, Berthold von Neiffen, to Italy to safeguard the imperial rights. Pope John XXII, however, declared the German throne to be vacant. On Oct. 8, 1323, in Avignon, the pope accused Louis "the Bavarian" of having illegally assumed political rights; threatened him with excommunication if he did not resign the royal crown within three months; and for the meantime nominated King Robert of Naples as imperial vicar for Italy. Louis denied that papal approbation was required for the grant of the German crown, which could only be made by the German electors, and he appealed to a general council of the church. Despite the scruples of several cardinals, he was excommunicated by the pope on March 23, 1324, and deposed on July 11. Louis opposed this decision in several public appeals, in which he also hinted that the pope was a heretic.

In Jan. 1327 Louis marched to Italy; he was crowned in Milan as king of Lombardy on May 31, 1327, and as emperor in Rome by Sciarra Colonna and representatives of the Roman people on Jan. 17, 1328. This elevation to the imperial dignity without any

ecclesiastical participation was given theoretical justification by the Franciscans Marsilius (*q.v.*) of Padua and Jean de Jandun, who based all political power on the will of the people. Louis then set up the Franciscan, Pietro Rainalducci, as his antipope under the style of Nicholas V and launched an unsuccessful campaign against Robert of Naples. In Feb. 1330, however, he returned to Germany, after which Nicholas V submitted to the curia at Avignon.

Louis continued his war of propaganda against the Avignon papacy, mainly with the help of the learned leaders of the Franciscan Order, who at this time had their centre in Munich: namely the general of the Order, Michael of Cesena; the procurator, Bonagratia of Bergamo; and the head of the English province, William Ockham. Nevertheless Louis tried repeatedly to reach an understanding with the papacy, even offering his own abdication. After John XXII's death (Dec. 4, 1334), negotiations with his successor, the French Cistercian Benedict XII, proved promising at first, and Louis agreed to submit to a canonical suit of reconciliation; but the interference of Philip VI of France scotched this plan. Consequently Louis allied himself with Edward III of England against the common enemy, France.

The implacability of the curia finally provoked the German electors to take sides openly against the papacy at the assembly of Rhens (Rense, on the Rhine; July 16, 1338) in order to safeguard their electoral rights and the rights of the empire. At the diet of Frankfurt (Aug. 4, 1338) the decree *Licet juris* reaffirmed that the election to the German crown takes place without any participation of the papacy and establishes in itself a claim to the imperial dignity. In Sept. 1338 Edward III appeared at the diet of Coblenz; Louis recognized his claim to the French throne and made him vicar-general of the empire.

German public opinion, both among the laity and among the clergy, was now clearly on the side of Louis, but he did not exploit this favourable situation. Instead he broke off the alliance with Edward III at the beginning of 1341 (he had anyhow given him no help against France) and concluded an alliance with the French king, apparently hoping thus to achieve reconciliation with the curia. This did not come about, however, either with Benedict XII (who died in April 1342) or with his successor Clement VI, another Frenchman. The German princes too were changing their minds because of Louis' unscrupulous dynastic policy. His first wife Beatrice, daughter of the Silesian prince Henry III of Glogau (Glogow), having died in 1322, Louis had in 1324 married Margaret, daughter of Count William III and I of Holland and Hainaut; and when her brother William IV (II) died in 1345 in battle against the Frisians, Louis invested his wife with these counties. Similarly, when the heiress of Tirol, Margaret Maultasch, had driven her husband John Henry of Luxembourg out of her country (Nov. 1341), Louis annulled their marriage and married Margaret to his own son Louis, whom he had already invested with the margraviate of Brandenburg in 1324 (the Ascanian line of margraves having died out in 1320). Pope Clement VI could consequently exploit the anxiety of the German princes and, in particular, the resentment of the house of Luxembourg in order to obtain the election of John Henry's brother Charles of Moravia (*see* CHARLES IV, Holy Roman emperor) as antiking on July 11, 1346. Philip VI of France adhered to the Luxembourg faction, but he and Charles's father, King John of Bohemia, were defeated by Edward III at Crécy (Aug. 26, 1346). Thereupon Louis renewed negotiations with the English king; but he died on a bear hunt near Munich on Oct. 11, 1347. He was buried in Our Lady's church in Munich, but his body has disappeared; his tomb is a beautiful cenotaph of the 15th century.

Conclusions.—The emperor died undefeated, though he had had to fight for 33 years against ever new enemies and till 1338 practically without the support of the electoral princes. With no regard for his own person he consistently defended the right of the empire to elect a king independently of the papacy. His protection of the towns and his care for commerce and communications are quite remarkable. The Bavarian law code of 1333–34 was a valuable contribution to law and order, which he furthered also by trying to establish public peace throughout Germany. Yet he

appeared inconsequent and irresolute because of his unfortunate choice of means with which to carry out his policy and because of his yielding, time and again, to changing influences.

LOUIS I (1786–1868), king of Bavaria from 1825 to 1848, was born on Aug. 25, 1786, in Strasbourg, the son of the future king of Bavaria, Maximilian I Joseph, and his consort Auguste of Hesse-Darmstadt. Against his inclination he saw service at Napoleon's headquarters in the campaigns of 1806–07 against Prussia and of 1809 against Austria. He objected to the Confederation of the Rhine and to Bavaria's alliance with France, which he regarded as treason against Germany. He also objected to his father's ecclesiastical policy, particularly to the secularization of the monasteries. For all these policies he blamed the leading Bavarian minister, Maximilian von Montgelas, in whose fall from power (Feb. 2, 1817) he played an active part. The Bavarian constitution promulgated in 1818 owed something to ideas that Louis had expressed when its draft was under consideration.

Because of his liberal tendencies and his emphatically German outlook, the accession of Louis to the throne was generally welcomed on his father's death (Oct. 13, 1825). Politically he did not fulfill his subjects' hopes. He soon came into conflict with the diet, and after the July revolution of 1830 in France he distrusted all democratic institutions. Up to 1837, however, the conciliatory minister for internal affairs, Ludwig, prince von Ottingen-Wallerstein, the king's personal friend, prevented the situation from worsening. Then, in 1837, a new ministry took office, under Karl von Abel, who had won the king's favour by promoting the restoration of the monasteries. Abel adopted a strictly reactionary and clericalist course, which lost the king many sympathies. Moreover, Louis I's lofty conception of royalty and his near-deafness made him more and more unyielding. Despite his strong German patriotism he made no move to change the unsatisfactory structure of the German confederation. His enthusiasm for Greece—where he traveled in 1835–36—made him promote the election of his second son to be king of Greece (*see* OTTO) in 1832. The difficulties caused by Abel's mistaken policies were further aggravated by the king's passion for the dancer Lola Montez, whom he created Gräfin Landsfeld. Eventually, on March 20, 1848, revolution broke out and Louis abdicated next day in favour of his son Maximilian II.

Louis I's real significance lay in his patronage of the arts. From his journeys as a crown prince to France and Italy he had already brought home valuable sculptures and portraits, which later formed the nucleus of the collections in the Glyptothek and the Pinakothek in Munich. As king he began the large-scale planning of Munich, whose present layout bears his stamp. L. Klenze and F. von Gaertner, his favourite architects, created the noble style of Munich classicism. Louis also united the royal collections of paintings under the guidance of G. von Dillis, enlarged them generously and commissioned Klenze to build the Alte Pinakothek as a suitable permanent home for them (1846–48). A series of representative buildings in Munich (Königsbau of the royal palace, Alte and Neue Pinakothek, Glyptothek, Propyläen, church of St. Boniface, the layout of Ludwigstrasse and Königsplatz, etc.) and in the country (Walhalla near Straubing, Hall of Liberation near Kehl) owe their existence to Louis. He also moved the Bavarian university from Landshut to Munich in 1826.

Louis died in Nice on Feb. 29, 1868. By his marriage (1810) with Therese of Saxe-Hildburghausen he had four sons (Maximilian II of Bavaria; Otto of Greece; the future regent Luitpold of Bavaria; and Adalbert) and four daughters.

LOUIS II (1845–1886), king of Bavaria from 1864, was born at Nymphenburg on Aug. 25, 1845, the son of Maximilian II and his consort Marie of Prussia. On March 10, 1864, at his father's death, he succeeded to the throne, just when he was about to begin his university studies. His first difficulties and disappointments were caused by his romantically enthusiastic relations with the composer Richard Wagner, whom he called to Munich in 1864. He paid Wagner's debts and became utterly absorbed in his plans. This friendship with Wagner provoked strong objections both from the government and from the population. Rumours to the effect that Wagner exerted influence over politics and Wagner's own improprieties accentuated the conflict, so that in Dec. 1865 Louis had to expel him from the country, although he was always to remain his friend and patron.

In the Seven Weeks' War of 1866 Bavaria, on the advice of the prime minister Ludwig von der Pforden, took Austria's side. After the defeat Louis appointed as prime minister Chlodwig, prince von Hohenlohe-Schillingsfürst, to whose abilities Wagner had drawn his attention. Hohenlohe, with Louis' approbation, conducted a policy that loyally fulfilled the obligations of the Prussian alliance of 1867 and resisted all attempts by the French emperor Napoleon III to win Bavaria over to his side, but at the same time safeguarded Bavaria's rights of sovereignty against Prussian encroachments. After the French declaration of war against Prussia in 1870 Louis at once joined Prussia's side; and in December he let himself be persuaded by Bismarck to address a letter to the German princes and free cities suggesting that they form a German empire with a German emperor. Though Bavaria obtained a number of special rights within this empire, the king's demands for increase of territory and for the alternation of the imperial title between the Bavarian and Prussian dynasties remained unfulfilled.

Louis was not satisfied with the solution of the German question and was mortified by the patriotic enthusiasm of the Bavarian population. His ministers' resistance to his wish to improve the position of the Roman Catholic Church was a further disappointment for him. Also his romantic ideas of royalty clashed with the limits set by the constitution. Consequently the king retired more and more into his dreams: only rarely could his ministers obtain an audience. From 1882 onward his seclusion from the world became increasingly morbid. His patronage of the arts finally developed into a romantic mania for building: in Herrenchiemsee he created a copy of Versailles which was never entirely completed (1878–85); the castles of Linderhof (1869–78) and Neuschwanstein (1869–86) were completed; the plans for another castle at Falkenstein and for a Byzantine palace remained on paper. Finally, he was declared insane because of advanced paranoia, and on June 10, 1886, his uncle, Prince Luitpold, assumed the regency. The proceedings of the state commission that visited Neuschwanstein on that day were, however, shamefully tactless. Louis was taken to Berg, on Lake Starnberg, by the psychiatrist Bernhard von Gudden. There, on June 13, 1886, he drowned himself, and Gudden, too, lost his life in an attempt to save him.

(K. O. v. A.)

LOUIS III (1845–1921), king of Bavaria from 1913 to 1918, was born in Munich on Jan. 7, 1845, the son of the future regent Luitpold. He was badly wounded in the Seven Weeks' War (1866). In 1868 he married Maria Theresa, daughter of the archduke Ferdinand of Austria-Este. In Dec. 1912, on his father's death, he took over the regency for the insane King Otto, but on Nov. 5, 1913, he assumed the royal title himself. Louis was interested chiefly in agriculture and transport, but also continued the traditional Wittelsbach patronage of the arts. In World War I he showed no initiative whatever, though from 1917 he was convinced that Erich Ludendorff's policies would prove to be erroneous. The Bavarian revolution of Nov. 7–8, 1918, took him completely by surprise. Though he did not abdicate he released

his officials and officers of their oath of loyalty on Nov. 13, 1918. An embittered man, he died on Oct. 18, 1921, at Sarvar in Hungary.
(K. O. v. A.)

LOUIS THE GERMAN (c. 806–876), king of the East Franks from 843, was the third son of the Carolingian emperor Louis I (q.v.) the Pious. At the partition of the empire in 817, he received Bavaria, which remained the core of his kingdom, with its centre at Regensburg. He began his rule in 826 and married Emma (d. 876), daughter of Count Welf and sister of his stepmother Judith in 827. Louis took part in the revolts against his father (830–833) and joined with his half brother Charles the Bald in opposing the claim of Lothair I (q.v.) to imperial suzerainty over the whole empire after the death of their father in 840. Louis and Charles defeated Lothair at Fontenoy (June 25, 841) and confirmed their alliance by the oaths of Strasbourg (Feb. 14, 842), famous as early records of the Romance and Germanic languages. The treaty of Verdun (843) gave Louis all lands east of the Rhine except Friesland, together with Speyer, Worms and Mainz west of the Rhine. He thus obtained the East Frankish empire, comprising territory of the Franconians, the Swabians, the Bavarians and the Saxons, which was in the course of time to become Germany.

At the time, the division of 843 was not held to be final. The opponents of Charles the Bald, now king of the West Franks, appealed to Louis for help, and he sent his son Louis (q.v.) the Younger with an army to Aquitaine in 854 and went himself to the west, with the intention of deposing Charles, in 858. Both expeditions, however, were unsuccessful, and at the peace of Coblenz (June 7, 860) Louis renounced his claims. When his nephew Lothair (q.v.) of Lotharingia wanted to divorce his wife, Louis at first supported him in return for a promise of the cession of Alsace (860); but in 865 he made a treaty with Charles and in 867 they envisaged a division of Lothair's kingdom. After Lothair's death (869) Charles claimed all Lotharingia, but at the treaty of Mersen (Meerssen), in 870, Louis insisted on a division following roughly the course of the Meuse river. Not yet thinking in terms of a permanent East Frankish realm, Louis in 865 and 872 divided the country between his sons Carloman, Louis the Younger and Charles III the Fat. Internal quarrels as well as discontent at the partitions led to revolts by one or another of the sons in the period 861–873, but these were no serious danger to the realm.

Louis the German's kingdom was also free of grave danger from abroad. The sack of Hamburg in 845 was the only damaging raid by the Northmen. The most important problem in foreign affairs was posed by the long frontier with the Slavs, which was also the frontier of Western Christian civilization. In the north Louis contented himself with minor defensive expeditions, especially against the Obodrites and Sorbs; his main interest was directed toward Bohemia and Moravia, where he also supported the Christian missions. These, however, did not make much progress among the Czechs, though 14 nobles were baptized at Regensburg in 845. Moravia was given by Louis as a fief to the Christian noble Rastislav in 846, but the latter revolted in 855 and called the Greek missionaries Cyril and Methodius into his country (862–863), thus counteracting the Frankish Catholic influence. In 870 Rastislav was deposed by his nephew Svatopluk (Zwentibold), whose victorious war against Louis enabled him to found the kingdom of Greater Moravia and to achieve independence at the peace of Forchheim (874), even though he had to pay tribute to Louis.

Louis was unsuccessful in his endeavour to gain the imperial dignity and the succession in Italy for his line after the death of his nephew the emperor Louis II. The empress Angilberga in 872 and Louis II in 874 had declared in favour of Carloman, Louis the German's eldest son; but when Louis II died (Aug. 12, 875) Charles the Bald had himself crowned by Pope John VIII (Christmas 875). Louis the German was preparing for war against Charles when he died, at Frankfurt, on Aug. 28, 876. He is buried at Lorsch.

(T. SCH.)

LOUIS THE YOUNGER (c. 830–882), king of part of the East Frankish realm, was the second son of the Carolingian Louis (q.v.) the German and his Welf wife Emma. He was married to Liutgard (d. 885), daughter of the Saxon noble Liudolf, ancestor of the Liudolfing dynasty. He invaded Aquitaine unsuccessfully in 854, on his father's orders. According to the arrangements of 865 and 872, he received Franconia, Thuringia and Saxony after his father's death (876). His victory at Andernach over the West Frankish king and emperor Charles the Bald (Oct. 8, 876) assured him the possession of eastern Lotharingia, which the treaty of Mersen (Meerssen) of 870 had assigned to the Eastern kingdom. By intervening in West Frankish affairs he acquired also western Lotharingia through the treaties of Verdun (879) and Ribémont (880). He died in Frankfurt on Jan. 20, 882, and is buried at Lorsch.

See E. Dümmler, *Geschichte des Ostfränkischen Reiches*, vol. 2–3, 2nd ed. (1887–88); P. Kehr, *Die Kanzleien Karlmanns und Ludwigs des Jüngeren* (1933). (T. SCH.)

LOUIS THE CHILD (893–911), East Frankish king from 900, was born at Altötting in Bavaria, the son of King Arnulf and his wife Ota. Declared heir to the kingdom in 897 and, after Arnulf's death, crowned king at Forchheim on Feb. 4, 900, he also received the allegiance of the Lotharingians after the death (Aug. 900) of his half-brother Zwentibold, who had ruled Lotharingia from 895. In theory the boy king was himself the ruler, in fact the government was exercised by Archbishop Hatto I (q.v.) of Mainz. The kingdom was too weak to stop the raids of the Magyars, more and more frequent from 900: they defeated the Bavarians at Bratislava on July 4, 907, and the king's army near Augsburg in Aug. 910. Bavaria, Franconia, Swabia and Saxony all fell under the sway of local aristocrats, the ancestors of the later ducal dynasties. Louis died on Sept. 24, 911; he is buried near Regensburg. He was the last of the East Frankish Carolingians.

LOUIS I, king of France: see **LOUIS I** the Pious, Carolingian emperor.

LOUIS II LE BÈGUE or **THE STAMMERER** (846–879), king of France (i.e., Francia Occidentalis, the West Frankish kingdom) from 877 to 879, was the son of Charles II the Bald and of Ermentrude. After the death of his younger brother Charles (866), he was made king of Aquitaine but remained under his father's tutelage.

Elected king in Dec. 877, after his father's death, Louis provoked almost immediate opposition from the magnates by attempting to redistribute the great offices of state and had to abandon his plans. Pope John VIII, who held a council at Troyes (878), quickly saw that he could hope for no assistance from this ailing king. In the same year Louis agreed with his cousin, Louis the Younger, ruler of the East Frankish kingdom, to maintain the division of Lotharingia, arranged by their respective fathers in the treaty of Mersen (870). Louis II, who had been ill for some months, died at Compiègne on April 10, 879.

See L. Halphen, *Charlemagne et l'empire carolingien* (1947). (J. DE.)

LOUIS III (c. 863–882), king of France (i.e., Francia Occidentalis, the West Frankish kingdom), from 879 to 882, was a son of Louis II le Bègue. He and his brother Carloman succeeded to the throne on their father's death in April 879; but the legitimacy of the two young kings was questioned, and Louis the Younger, ruler of the East Frankish kingdom, invited by the West Frankish nobles, twice attacked their kingdom and was bought off only by the grant of that part of Lotharingia which Charles the Bald had acquired in 870.

Louis III ruled northern France from the channel to the Loire. He took part in the concerted Carolingian campaign against the usurper Boson of Provence in 880–881. For himself he won a brilliant victory over the Normans at Saucourt in Aug. 881 and freed the Loire from another Norman incursion in 882. He died, after an accident, on Aug. 5, 882.

See E. Dümmler, *Geschichte des Ostfränkischen Reiches*, 2nd ed. (1887–88); L. Halphen, *Charlemagne et l'empire carolingien* (1947). (J. DE.)

LOUIS IV D'OUTREMER or **FROM OVERSEA** (921–954), king of France from 936 to 954, was the son of Charles III the Simple and of Eadgifu, daughter of the Anglo-Saxon king Edward the Elder. When his father was imprisoned (923) Louis was taken to England, and he remained there until he was summoned back to France by Hugh (q.v.) the Great. Elected king in June 936, he surprised the factions that had hoped to exploit him by his forceful policy. He showed his independence of Hugh by moving from Paris to Laon and by choosing as his chancellor not Hugh but Archbishop Artaud of Reims. He intended, moreover, to recover the alienated properties of the crown. To counterbalance the immense power in Neustria of Hugh the Great and Herbert of Vermandois, he tried to build up a strong base in the east. He reconquered key positions on the Meuse, but his attempt to take control of Lotharingia by accepting the homage of its duke Gisbert in 939 brought the German king Otto I, Hugh and many of his vassals into coalition against him. After Gisbert's death Louis married his widow Gerberga, who was also Otto's sister, but Otto recovered Lotharingia. In Nov. 942 the two kings made the peace of Vise, whereupon Hugh had to submit.

Meanwhile, perhaps in accordance with a plan to set up ecclesiastical feudatories in opposition to the secular vassals, Louis had in 940 given the county of Reims to Artaud. This provoked an attack on Reims by many of the magnates; Louis lost the town and Artaud fled. However, a tour of Aquitaine and southeastern France (941) elicited support for Louis in those areas; and William Long-Sword, duke of Normandy, did homage to him. When the Normans invaded Brittany after the accession of William's young son Richard I (942), Louis cleverly involved Hugh, who had wanted to stir up trouble, in his intervention against them; but in the summer of 945 he was captured by treachery and handed over to Hugh's power. He had to buy his freedom with the cession of Laon. Then Otto came to his aid; together they recaptured Reims, Artaud was restored as archbishop, and Hugh was excommunicated at the synod of Ingelheim (948), which condemned all attempts against the king's authority. When Louis died at Reims on Sept. 10, 954, few of his projects had been realized, but the succession of his son Lothair was assured.

LOUIS V LE FAINÉANT or **DO-NOTHING** (967–987), king of France, sole ruler from 986 to 987, was crowned on June 8, 978, during the lifetime of his father Lothair. Shortly afterward he was married to Adelaide, widow of an Aquitanian count, and established as king in Aquitaine; but his frivolity and his abandonment of his wife, who finally ran away, brought him into discredit. Sole king on his father's death (March 986), Louis disregarded the advice of his mother, Queen Emma, and Archbishop Adalbero of Reims, who wanted him to come to terms with the German king Otto III; instead, he sought the aid of Hugh Capet (q.v.) against Otto. Hugh, however, would not commit himself. Louis had just begun military operations and a lawsuit against Adalbero when he died, as a result of a hunting accident, on May 21 or 22, 987. He was the last Carolingian king of France, as Hugh Capet was chosen to succeed him instead of his unpopular uncle, Charles of Lower Lorraine, the only surviving member of the dynasty.

LOUIS VI LE GROS or **THE FAT** (1081–1137), king of France, was the son of Philip I and Bertha of Holland. Associated with his father as king elect from c. 1098, he succeeded to the crown on Philip's death (1108). He married Adelaide of Savoy c. 1115.

Louis VI was the first among the Capetians to appreciate and to take in hand the basic problem confronting the dynasty, that of enforcing order within the royal domain. To assure safe travel

particularly along the route from Paris to Orléans, Louis waged relentless war against the pillaging lords of the Île de France, men such as Hughes du Puiset (1109 and 1118), Hughes de Crécy (1118) and Thomas de Marle, whose stronghold of Coucy (*q.v.*) he finally captured in 1130. During the same period he was engaged in a series of wars (1109–13 and 1116–20) against Henry I of England, who had captured his own eldest brother Robert in 1106 and so had become effective master of Normandy. Though worsted in these wars, Louis continued to support Robert's son, William Clito, to whom he gave the county of Flanders in 1127, after the murder of Count Charles the Good (the Flemings, however, supported a rival candidate, Thierry of Alsace, who became count after William's death in 1128). When the Holy Roman emperor Henry V invaded France in alliance with the English king, in 1124, all the great vassals rallied to Louis and the emperor retreated. In all these campaigns Louis led his armies in person, gaining a great reputation as a warrior.

Louis gave some encouragement to the growth of communes—preferably, however, in towns on his vassals' lands and only rarely to towns in the royal domain. In his own territory he created privileged rural communities, such as that of Lorris-en-Gâtinais, aiming to attract the peasants to work in them. He established good relations with the clergy, protecting ecclesiastical property from the attacks of brigand lords; and he supported the reforming work of the Cistercians and Premonstratensians. His principal counselors were likewise ecclesiastics: namely Étienne de Garlande (the most powerful member of a family much favoured by Louis), who became his chancellor; and Suger (*q.v.*), abbot of St. Denis, his most trusted and influential minister after Étienne had fallen into disfavour (1124) and who became his biographer. When Louis died, on Aug. 1, 1137, he had just effected the marriage between his heir, Louis VII, and Eleanor, heiress of Aquitaine.

LOUIS VII LE JEUNE or **THE YOUNG** (c. 1120–1180), king of France as sole ruler from 1137, was the son of Louis VI and Adelaide of Savoy. He was associated with the throne and crowned king in 1131 after the death of his elder brother Philip. He married Eleanor (*q.v.*), heiress of Aquitaine, in July 1137 and began his effective reign upon his father's death a few days later. His desire to appoint to the archbishopric of Bourges one of his chaplains, Cadurc, instead of Pierre de La Châtre, the canonically elected candidate, brought him into serious conflict not only with the Holy See but also with Thibaut IV of Blois, who since 1125 was also count of Champagne. As Louis refused Pierre entry into Bourges, Pope Innocent II laid an interdict on France, and Thibaut, who had come into the quarrel by giving refuge to Pierre, was further impelled to support the pope when Raoul of Vermandois, the king's seneschal, repudiated his wife, Thibaut's niece, in order to marry a sister of Queen Eleanor. Louis invaded Champagne, burnt Vitry-sur-Marne (1142) and occupied various other towns. Pope Celestine II, however, who succeeded Innocent in 1143, raised the interdict on condition that Pierre de La Châtre should retain Bourges; and in 1144 St. Bernard made peace between the king and Thibaut.

Soon afterward (Easter 1146) Louis VII took the cross when St. Bernard preached the second crusade at Vézelay. Louis set out for Palestine in June 1147, leaving Suger, abbot of St. Denis, as his regent; but the crusade (*see* CRUSADES) was not a success and the king returned to France in Nov. 1149. From that time onward Louis devoted himself to developing the resources of the royal demesne; and he increased the number of peasant agricultural communes, of the sort first encouraged by his father. He was now, moreover, on good terms with the church, and appeals by the clergy for his protection enabled him to intervene with profit outside his own demesne, notably in Auvergne, in Burgundy and in Narbonne. In 1147 he welcomed Pope Eugenius III as a refugee in France; and in 1162 he likewise received Alexander III, whom indeed he had been one of the first rulers to recognize (1160) after the emperor Frederick I Barbarossa had set up the antipope Victor

IV (1159). Even so, in a fit of pique, he went so far as to meet Frederick and Victor IV at St. Jean-de-Losne in Aug. 1162; but he came to no agreement with them.

By far the most outstanding threat to Louis VII's position came from the growing power of the counts of Anjou (*q.v.*). Geoffrey IV Plantagenet conquered Normandy (1140–44) in the name of his wife Matilda; and when Louis, on remote grounds of consanguinity, had had his marriage with Eleanor annulled (March 1152), it was Geoffrey's son and successor Henry whom she married (May) thus bringing Aquitaine to him. The Angevin power thus appeared to overshadow the French monarchy in France itself; and in 1154 the count became king of England also, as Henry II (*q.v.*). From then until Louis VII's death the two rulers pursued their rivalry by recurrent warfare and perpetual intrigue. Louis was on the whole successful in preserving his demesne from incursions; and he was aided by the quarrel (1164–70) between Henry II and Thomas Becket, archbishop of Canterbury, and later by the revolt (1173–74) of Henry's sons, whom Louis actively encouraged. Against Henry of England, he was able to obtain an alliance with the brothers Thibaut V of Blois and Henry I of Champagne, whose sister Alice or Adela he married after the death of his second wife, Constance of Castile, in 1160. He was also supported by Philip of Flanders, and, less steadily, by Raymond V of Toulouse. Louis died in Paris on Sept. 18, 1180.

LOUIS VIII COEUR-DE-LION or **LIONHEART** (1187–1226), king of France from 1223, was born in Paris on Sept. 5, 1187, the eldest son of Philip II and Isabella of Hainaut. He was married in 1200 to Blanche (*q.v.*), daughter of Alfonso VIII of Castile, the French receiving as her dowry the long-disputed lordships of Issoudun and Graçay in Berry. As eager as his father to extend Capetian authority, Louis lacked Philip's diplomatic finesse; and his seizure in 1212 of St. Omer and Aire on the Flemish border drove the count of Flanders, Ferrand or Ferdinand of Portugal, into alliance with the emperor Otto IV and John of England. When they invaded France in 1214, Louis opposed John in Poitou, routing him at the battle of La Roche-aux-Moines (*q.v.*).

During the autumn of 1215 John's rebellious barons offered Louis the English crown, and in April 1216, at a great assembly held at Melun, the French prince's claim to England by right of his wife, a granddaughter of Henry II, was propounded. It was also fictitiously alleged that John's crown had been declared forfeit by the court of France as early as 1203 in punishment for the murder of Arthur of Brittany. Louis landed in England in May 1216 and joined the rebel barons in London. Though he and his adherents were almost immediately excommunicated, his cause prospered until John's death in October removed the excuse for the adventure, rendering Louis an embarrassment rather than an asset to his supporters. These were severely defeated at Lincoln in May 1217 and a French force was destroyed off Dover in August; by the treaty of Kingston in Sept. 1217 peace was made in England and Louis agreed to withdraw. By a secret arrangement he was paid 10,000 marks.

Louis had been in the south of France during the elder Simon de Montfort's crusade against the Albigenses in 1215; he returned there briefly in 1219, and with Simon's son Amaury directed the massacre of heretics at Marmande.

Philip II died in July 1223 and Louis VIII was crowned at Reims on Aug. 6. He attacked the English power in the southwest in 1224, overrunning Poitou and part of Gascony. He led an army against the Albigenses in 1226, forcing Avignon to capitulate on his way south, and receiving the submission of Languedoc. These achievements facilitated his plans for the appanages which in his will he devised for his younger sons, Robert, count of Artois, Alphonse, count of Poitiers, and Charles, count of Anjou. Louis died at Montpensier in Auvergne on his way back to Paris on Nov. 8, 1226, and was succeeded by his eldest son Louis IX.

BIBLIOGRAPHY.—C. Petit-Dutaillis, *Étude sur la vie et le règne de Louis VIII* (1894); E. Lavisse, *Histoire de France*, vol. iii (1901); R. Fawtier, *Les Capétiens et la France* (1942), Eng. trans. by L. Butler and M. J. Adam, *The Capetian Kings of France. Monarchy and Nation 987–1328* (1960).

LOUIS IX (SAINT LOUIS) (1214–1270), king of France from 1226, was born at Poissy, near Paris, on April 25, 1214, the eldest surviving son of Louis of France, afterward Louis VIII, and Blanche of Castile. His father, who became king in 1223, died on Nov. 8, 1226; Blanche became regent for her young son and arranged for his immediate coronation at Reims (Nov. 29, 1226). During the following years the queen mother had to suppress a serious feudal revolt, the principal leaders of which were Peter of Dreux (Pierre Mauclerc), duke of Brittany, and the king's uncle Philippe Hurepel, count of Boulogne, supported by Count Raymond VII of Toulouse and by the English king Henry III. In her struggle Blanche was advised and supported by the papal legate Romano Cardinal Frangipani. By the treaty of Meaux, often called the treaty of Paris (1229), the count of Toulouse was reduced to submission. The marriage (1239) of his daughter and heiress Joan with Louis IX's brother Alphonse of Poitiers was planned; the annexation of the *sénéchaussées* of Nîmes, Béziers-Beaucaire and Carcassonne to the royal domain was confirmed; and measures to assure the extermination of the Albigensian heresy in Languedoc were agreed. The other rebels were subdued in 1230; a further rebellion by Mauclerc (1234) was of short duration. Blanche arranged the king's marriage (May 1234) to Margaret (*q.v.*), daughter of Raymond Berengar of Provence. Louis had by then been for several years old enough to undertake the government himself, but his mother continued to conduct affairs at least until 1242, possibly later, and she was regent in France from the time of Louis' departure on crusade (Aug. 1248) until her death (Nov. 1252).

However, once he had assumed control of affairs, Louis ruled his kingdom with wisdom and authority, achieving order at home and peace abroad. His reputation for sanctity attracted many near-contemporary biographers, the best-known of whom was Jean, sire de Joinville (*q.v.*). The accounts of hagiographers might well be suspect, but the records of Louis IX's administrative enquiries and ordinances clearly show his strength and ability. Moreover, England under Henry III was suffering a series of constitutional crises, and in Germany the emperor Frederick II's quarrel with the papacy was followed by the Great Interregnum (1254–73) during which there was no effective sovereign; France, therefore, naturally became the predominant power in western Europe.

Louis' Achievements in France.—Just as he was assuming control of affairs, the young king was faced with a fresh baronial revolt (1242) in the south and southwest, fomented by Henry III. Louis defeated the English at Taillebourg and at Saintes; and Raymond of Toulouse, who had been a leader of the revolt, was obliged to make peace with him at Loris in Jan. 1243. After this, Louis IX's reign was peaceful. He kept very close control over his officers, *baillis* and *seneschals*, frequently sending other officials to investigate their conduct and to hear complaints from those subject to their authority. These large-scale inquests or enquiries showed that Louis' provincial administration was on the whole efficient and his officials honest. The duties and obligations of officials in the royal domain were carefully outlined in the ordinances of 1254 and 1256; they had to swear not to take bribes or practise extortion and they were obliged to remain for 40 days in a district after their term of office had expired, so that any plaintiff would have time to prefer a case against them. Moreover, they were forbidden to frequent taverns or to gamble; and business activities such as the purchase of land or the marriage of their daughters could only be carried out with the king's consent. Subsequent ordinances further centralized and strengthened the government of the royal domain; and that of 1258, abolishing the judicial duel or ordeal by battle, already forbidden by the church at the fourth Lateran Council of 1215, increased the scope of royal justice. Louis was also concerned with public order; prostitution and gambling were forbidden and the edict of 1268–69 imposed particularly severe penalties for blasphemy.

Ordinances of 1263 and 1265 gave compulsory circulation to the royal coinage; Louis minted several silver coins and one gold one (with a *titre fine* to 999/1,000); counterfeiting was heavily penalized and the relative value of other currencies in the kingdom was fixed. Louis established a closer control over the city of Paris, transferring some of its financial burdens to the royal treasury and appointing as provost Étienne de Boileau, who wrote the *Livre des métiers*, the earliest known collection of the rules and statutes of the various city guilds.

During Louis' reign, and certainly as a result of his influence, a certain specialization of function and personnel began to develop in the *curia regis*, the king's traditional feudal court. Certain of its sessions became reserved exclusively to judicial, others to financial affairs. In the course of time these distinct sessions came to bear special names, the judicial meeting developing into the *curia in parliamentum domini regis* (that is, the *parlement*) and the financial meeting into the *curia in compotis* or court of accounts.

Louis continued the policy of increasing the royal domain wherever possible. Already enlarged by the provisions of the treaty of Meaux-Paris (1229), the domain was further increased by the acquisition of Clermont-en-Beauvaisis, Mortain and Domfront after the death of Philippe Hurepel (1234) and by the purchase of the county of Mâcon from Burgundy (1239). The king's policy of granting appanages to his brothers and younger sons has sometimes been criticized; for the former, however, he was merely carrying out the terms of his father's will; and in any case he was strong enough to control his family, while the careful administration of rulers such as Alphonse of Poitiers in fact tended to extend rather than diminish the royal power.

Foreign Relations.—Since his dominating aim was to recover the holy places for Christendom, Louis was particularly anxious to achieve and maintain peace among Christian princes.

The Treaties of Paris and Corbeil (1258–59).—After his victories at Taillebourg and at Saintes, Louis IX's relations with Henry III of England gradually improved, and negotiations begun in 1254 led to the treaty concluded in Paris in May 1258 and ratified in Dec. 1259. This agreement settled matters which had been in dispute since the time of Philip II Augustus of France and John of England. Henry III was recognized as duke of Aquitaine, for which he did homage to Louis; but he abandoned his claim to Normandy, Maine, Anjou, Touraine and Poitou. Louis in return not only gave back all that Henry's predecessors had held in fief or domain in the dioceses of Limoges, Cahors and Périgueux, but also promised Henry the reversion of the lands of Alphonse of Poitiers in Agenais and Saintonge, south of the Charente river, should Alphonse die childless.

Louis made a similar compromise agreement with James the Conqueror, king of Aragon. By the treaty of Corbeil (1258) he gave to James complete suzerainty over Roussillon and the county of Barcelona, while in return James renounced his claims to Provence and all of Languedoc except Montpellier.

The Papacy and Sicily.—In the struggle between the emperor Frederick II and the papacy Louis managed to maintain a neutral attitude; only when Pope Innocent IV fled to Lyons did he warn Frederick against pursuing him there. When his brother Charles of Anjou accepted the kingdom of Sicily (1265) from the pope, his support of the enterprise was passive, being limited to a permission to his subjects to fight in Charles's army.

The Seventh and Eighth Crusades.—Louis IX took the cross for the first time late in 1244, after an illness. He was particularly sensitive to the difficulties of Baldwin II, the Latin emperor of Constantinople who visited France in 1236 and in 1245–47 in an effort to raise money and men to maintain his inheritance not only against the Muslims but also against the Greeks. Baldwin sold Louis a relic of the Crucifixion, the Crown of Thorns to enshrine which Louis had the Sainte-Chapelle built (1245–48) in Paris. But the prolonged dissension between papacy and empire, and difficulties of organization delayed the French king's departure until Aug. 1248. Embarking at Aigues-Mortes in the south of France, the crusaders sailed, by way of Cyprus, to attack Egypt, the main centre of Muslim power. They captured Dam-

etta but were defeated at Mansurah (Feb. 8, 1250) and Louis was taken prisoner. He was subsequently ransomed and spent the next four years in Syria, where he fortified the towns held by the Latins and ransomed as many Christian captives as he could. He embarked for France in April 1254, believing that his mother's death made his return necessary. Even so, he remained determined to launch another crusade; though when at last he announced his plans in March 1267 they aroused markedly little enthusiasm among his counselors and court and his old friend Joinville openly told him that the plan was folly. Nevertheless, on July 1, 1270, the crusaders left Aigues-Mortes for Tunisia, which was to be used as a base for another attack on Egypt. The crusading army disembarked at Carthage but was immediately decimated by an epidemic of plague. Louis himself succumbed, and died before Tunis on Aug. 25, 1270.

Character and Achievements.—Louis was one of the greatest of the Capetian kings, a strong ruler and renowned for his sanctity. In Joinville's narrative we see him practising all the conventional pieties; but he translated his faith into action and sought not only to live but also to rule according to the precepts of religion. His piety rarely led him into undue subservience to the church; he kept firm control over episcopal appointments and allowed complaints against excessive papal taxation. Holding a very high conception of the office, rights and duties of a king, Louis was powerful enough to implement his theories. He was particularly anxious to maintain correct feudal relationships; thus, though some of his counselors grumbled that he was too generous to Henry III in the treaty of Paris, he was content because Henry became his vassal for Aquitaine. At the same time his conception of royal dignity made it inevitable that he should always uphold kingly power; when, by the Mise of Amiens (1264), he arbitrated between Henry III and the rebellious English barons, his decision could not have been other than in Henry's favour.

Louis regarded a king as the supreme judge in his kingdom; he gave personal attention to many of the pleas of his subjects, often holding court under an oak tree in the park adjoining his château at Vincennes. His reputation as a fair judge brought appeals for arbitration from all parts of Christendom; as well as giving judgment in the English dispute he had, by the Mise of Péronne (1246), settled the succession to the county of Flanders, disputed between the houses of Avesnes and of Dampierre. Louis IX's achievements and his reputation for undoubted sanctity brought immense prestige to the Capetian monarchy; in later times his reign was regarded as a period of great prosperity and happiness. He was canonized by Pope Boniface VIII on Aug. 11, 1297, and his feast day is Aug. 25.

LOUIS X LE HUTIN or **THE STUBBORN** (1289-1316), king of France from 1314 to 1316, had previously been king of Navarre from 1305 to 1314. The eldest son of Philip IV of France and of Joan (Jeanne) of Navarre, he was born in Paris on Oct. 4, 1289. He took the title of king of Navarre on his mother's death (April 4, 1305), but when he succeeded his father as king of France (Nov. 30, 1314) he resigned Navarre to his next brother, the future Philip V of France. In 1305 Louis had married Margaret, daughter of Robert II, duke of Burgundy, but in the last months of Philip IV's reign she was convicted of adultery and was later strangled in prison (1315). Louis married (July 1315) as his second wife Clémence, daughter of Charles I of Hungary; they were both anointed at Reims on Aug. 3, 1315.

Baronial discontent, which had become serious in the last year of Philip IV's reign, continued into that of Louis X. Louis' main policies were designed to allay this discontent and to gain support and money for a projected campaign against Flanders. He dismissed and imprisoned many of his father's unpopular ministers and allowed the execution of Enguerrand de Marigny. Charters were granted to groups of nobles in almost every province of France. Louis bought the support of the clergy by similar means, but whereas they gained for the church some real privileges, the use of ambiguous formulas made the baronial charters virtually worthless. Louis also sold their liberty to the serfs of the royal domain.

He led an expedition to Flanders in Aug. 1315, in order to enforce the treaty of Athis-sur-Orge (*q.v.*) made between his father and the Flemings in 1305, but bad weather obliged the French to retire. Louis died of pleurisy at Vincennes on June 5, 1316. By Margaret of Burgundy he had one daughter, Jeanne (1312-49), who married Philip, count of Évreux and (in her right) king of Navarre. By Clémence of Hungary Louis left a posthumous son, King John I.

LOUIS XI (1423-1483), king of France from 1461, was born at Bourges, in Berry, on July 3, 1423, the son of Charles VII of France by his consort Mary of Anjou. When Louis was born the English were ruling a large part of France (*see* HUNDRED YEARS' WAR), and he spent most of his childhood at the Loches in Touraine. Ugly, fat, spindleshanked and with a large head, Louis grew up in austere seclusion, to become secretive, rancorous, ruthless, superstitious though devout, careless in his dress and boorish in his manners, yet intelligent, well-informed, active, supple in diplomacy, courageous in war and able to command loyalty. Known as "the universal spider," he could still claim to personify the French national consciousness; as he was later to say to his rebellious feudatories, "I am France."

Dauphin, Rebel and Exile.—Louis was married to Margaret, daughter of James I of Scotland, at Tours in 1436—an unhappy union formed solely for political reasons. In 1439 the king sent him to superintend the defense of Languedoc against the English and then to act as royal lieutenant in Poitou. Louis, however, was impatient to reign and was induced by malcontent princes to put himself at the head of the Praguerie (*q.v.*) in 1440. Charles VII pardoned his rebellion and gave him direct control over the government of Dauphiné.

Louis took part in his father's campaigns of 1440-43 and in 1443 forced the English to raise their siege of Dieppe. When the Anglo-French truce of 1444 left numbers of mercenary troops without employment, he led a large body of them to attack Basel, in ostensible support of the German king Frederick IV (later emperor as Frederick III) in his quarrel with the Swiss confederacy. Having failed to take Basel, he launched his force against the Habsburg possessions in Alsace, since Frederick would not grant them the promised winter quarters. Meanwhile Charles VII had invaded Lorraine and was holding court at Nancy. When Louis rejoined him there, Charles was completely under the influence of Agnès Sorel and Pierre de Brézé. Father and son became wholly estranged after the death (1445) of the dauphine Margaret, whom Charles had liked. Detected in a plot against Brézé (Dec. 1446), Louis was exiled to Dauphiné. He was never to see his father again.

It was in Dauphiné that Louis served his apprenticeship as a ruler. Assuming the task of government himself, he set up a central chancellery (1447); divided the local administration between two *bailliages* and a *sénéchaussée* (1447); founded the University of Valence (1452); instituted a *parlement* (1453); reduced the nobles to obedience; and confirmed the privileges of the towns. He also applied himself to exploiting the country's mines and forests and to promoting its trade on the Rhône and across the Alps. Exercising full sovereignty, he pursued a foreign policy sometimes at variance with his father's. He fixed the frontiers

of Dauphiné by obtaining Savoy's renunciation of claims to Valentinois and Diois and the papacy's cession of its part of Montélimar (1447). A secret alliance with Savoy for a partition of the duchy of Milan (also 1447) was followed by the dauphin's marriage to Charlotte, daughter of Duke Louis I of Savoy, despite Charles VII's prohibition (1452). Subsequently, however, Louis fell out with Savoy; and in 1456, when Charles approached his frontiers with an army and summoned him to his presence, he fled to the Netherlands to the court of Philip the Good, duke of Burgundy.

Installed at Genappe in Brabant as Philip's guest, Louis could acquaint himself thoroughly with the working of the great Burgundian state, whose ruin he was later to seek so persistently (Charles VII remarked that Philip was feeding the fox that would eat his hens). At the same time Louis kept himself posted by spies with every detail of his father's illness, thus laying himself open to the unsubstantiated accusation, believed by Charles himself, that he had hastened his death by poison. At last, after five years of impatient exile, Louis became king of France when Charles died (July 22, 1461).

King of France.—On Aug. 15, 1461, Louis was anointed and crowned king at Reims. His first act was to strike at Charles VII's ministers. Pierre de Brézé and Antoine de Chabannes were imprisoned, but they and some of their more serviceable colleagues were subsequently reinstated. Relying largely on men drawn from the lower nobility or from the middle class, Louis formed a circle of loyal advisers who helped him to impose his authority, to enlarge the royal domain and to develop the wealth of the kingdom. Among them, Étienne Chevalier and Tristan Lhermite, as well as Brézé and Chabannes, had already served Charles VII, but Jean de Dailion, Oliver Le Daim (*q.v.*) and, from 1472, Philippe de Commines (*q.v.*) were Louis' own recruits.

Louis XI's major preoccupation was with the princes and great feudatories of the kingdom, who were ready to enleagué themselves with each other or with England against him. Former officers of Charles VII, such as Jean, comte de Dunois, stirred up hostility against the king's new men; Jean II, duc de Bourbon, and Francis II (*q.v.*) of Brittany emerged as the leaders of the malcontent nobility; Philip the Good's son and future successor, Charles the Bold, brought the power of Burgundy to the support of the king's enemies; and the king's own brother Charles de France (1446–72), at first duc de Berry, became a tool of the rebels.

In 1465 the malcontent princes formed the Ligue du Bien Public or League of the Public Weal to make war against Louis. All France seemed on the verge of anarchy, but the lesser gentry refused to rise against the king and the *bourgeoisie* rallied to him. After a successful campaign in Bourbonnais, Louis turned to confront the Burgundians, who were marching on Paris. He fought a battle with them at Monthéry (July 16) and then defended Paris against a siege. The league was brought to an end by the treaty of Conflans with the Burgundians (Oct. 5, 1465) and by that of St. Maur-des-Fossés with Brittany (Oct. 29), but Louis had to yield much: the Somme towns, which he had redeemed from Philip the Good for 400,000 crowns in 1463, were given back to the Burgundians; and Normandy was granted, in exchange for Berry, to Charles de France, so that all northern France, from Brittany to Burgundian Artois, would be linked in the hands of the former rebels. By Jan. 1466, however, the king had reoccupied Normandy, which in 1468 the assembly of the estates-general at Tours declared inalienable from the royal domain.

Charles the Bold, having become duke of Burgundy on Philip the Good's death (1467), allied himself with Francis of Brittany and with Edward IV of England; but in 1468 Louis invaded Brittany and, in September, detached Francis from the alliance. He then went to his disastrous interview with Charles the Bold at Péronne (Oct. 9–14, 1468). During the negotiations Charles learned of an insurrection in Liège, fomented by the French king's agents. Furious, he put Louis under house arrest, forced him to make far-reaching concessions and finally took him to Liège to witness the suppression of the revolt.

After his humiliation at Péronne, Louis attempted to nullify the Anglo-Burgundian alliance by assisting the Lancastrians against

Edward IV, but the final defeat of the Lancastrians (May 1471), put an end to this hope. Having already attacked Burgundy Louis found himself facing a new host of enemies, comprising not only Charles the Bold, Edward IV and Francis of Brittany but also powers in the southwest, namely Charles de France, to whom Louis had granted the duchy of Guienne in 1469, Jean V d'Armagnac and John II of Aragon, who hoped to recover Roussillon. However, the death of Charles de France, on May 24, 1472, occurred very opportunely for Louis; both Charles the Bold, who failed in his attack on Beauvais in the summer, and Francis of Brittany signed truces before the end of the year; the royal army overran Armagnac early in 1473; and in Sept. 1473 France and Aragon agreed to suspend hostilities in Roussillon. Charles the Bold then began scheming for a partition of France between Burgundy, England and other states and concluded the treaty of London with Edward IV (July 1474). Edward after nearly a year's delay launched the invasion of France for which his allies had been waiting, but Louis then bought him off with the treaty of Picquigny (Aug. 1475). Truces were then signed with Burgundy at Souleuvre (Sept. 13) and with Brittany at Senlis (Sept. 29). Already in March 1475 Louis had taken advantage of Aragon's difficulties to seize Perpignan.

After 1475 it remained for Louis to destroy the power of Burgundy. He subsidized the Swiss confederates and René II of Lorraine in their war against Charles the Bold, and Charles was defeated and killed in battle at Nancy on Jan. 5, 1477. Louis thereupon proceeded to dismember the Burgundian state, eager to reunite its French fiefs to the royal domain and to take as much else as he could. Charles the Bold's daughter Mary, however married the Austrian archduke Maximilian (*see* MAXIMILIAN I, Holy Roman emperor), who defended her inheritance against Louis. Finally, by the treaty of Arras (1482), Louis retained full sovereignty over the duchy of Burgundy, Picardy and Boulonnais and possession of Franche-Comté and Artois as the dowry of Margaret of Austria, fiancée of his infant son and heir, the future Charles VIII. The Austrians kept Flanders and the rest of the Netherlands.

Louis regarded war as a precarious enterprise and made it only with reluctance, though he maintained the standing army that Charles VII had instituted and strengthened the artillery. Diplomacy and inheritance were the means that he preferred for extending the royal domain. He purchased the rights of the heiress of the house of Penthièvre to the Breton succession; and he annexed Anjou and the French part of Bar on the death of René I, the titular king of Naples, in 1480 and Maine and Provence on the death of Charles II of Maine in 1481. Lorraine, however, was left to the house of Anjou; and Louis was too prudent to try to realize the Angevin claim pretensions to Naples.

Even so, Louis pursued an active policy in Spain and in Italy. His success in Roussillon was largely due to his exploitation of Aragon's difficulties in Catalonia and in the matter of the Castilian succession (from 1474). After Charles the Bold's death there was no one to prevent Louis from exercising a virtual protectorate over Savoy, where his sister Yolande was regent; and he made himself the arbiter of the affairs of northern Italy.

In France itself, having broken the resistance of the princes, Louis could impose his authority everywhere. Known for the strictness of his justice, he exacted prompt obedience from the *parlements* and thought of codifying the local customary laws. Ecclesiastical elections were taken under the royal control. The estates-general were convened only once, in 1468—and then merely to settle the question of Normandy (*see* above), not to air their grievances. Louis XI raised his revenues without consulting the estates and exacted sums of unprecedented magnitude from towns and countryside alike. Yet the *bourgeoisie* continued to support him: Jean de Beaufort of Tours, Pierre Doriole of La Rochelle and Guillaume Restout of Rouen were among his most trusted advisers, some of whom he used as diplomatic agents abroad. Louis viewed the national wealth as a factor in the power of the kingdom, sought to manage the economy, strengthening the guilds and promulgating numerous laws for industry. He encouraged municipal textile manufactures (notably the silk industry of Lyons and

Tours) and the introduction of printing at the Sorbonne (1470). Following the example of Jacques Coeur (*q.v.*), whose old assistants Jean de Villages and Guillaume de Varye he consulted, he took an interest in Mediterranean trade and even dreamed of a company to monopolize the spice trade. The fairs of Lyons and Rouen profited from his treaties with England and with the Hanseatic towns.

Of delicate health, Louis XI was a tireless worker, and overwork may have precipitated the cerebral arteriosclerosis which finally affected him. For his last two or three years he lived in seclusion at Plessis-les-Tours, in Touraine, where he died on Aug. 30, 1483. There is an edition of Louis XI's letters by E. Charavay and J. Vaesen, eight volumes (1883-1902).

LOUIS XII (1462-1515), king of France from 1498, was born at Blois on June 27, 1462, the son of Charles, duc d'Orléans, and Mary of Cleves. He succeeded his father as duc d'Orléans in 1465. In 1476 he was constrained to marry the saintly but misshapen Jeanne de France (1464-1505), daughter of his second cousin King Louis XI. During the minority of King Charles VIII he launched the revolt which ended in his defeat at St. Aubin-du-Cormier (July 28, 1488). Restored to favour in 1491 (after rigorous imprisonment), he commanded troops at Asti during Charles VIII's invasion of Italy (1494-95). When Charles was retreating he took Novara from the Milanese and held it during a long siege.

King of France on Charles VIII's death (April 8, 1498), Louis was crowned at Reims (May 27) and obtained from Pope Alexander VI the annulment of his marriage (Dec. 17). He then married Charles VIII's widow, Anne (*q.v.*) of Brittany, thus saving the personal union of her duchy and his kingdom. His next concern was to make good his claim to the duchy of Milan (*q.v.*), based on the marriage of his grandfather Louis de France, duc d'Orléans, to Valentina Visconti. His army, spreading terror deliberately, drove his rival Ludovico Sforza from Milan in summer 1499, and he visited Milan as duke in October. Ludovico re-occupied Milan in Feb. 1500 but was captured in April and died a prisoner in France.

Pursuing Charles VIII's claims to the kingdom of Naples (*q.v.*), Louis concluded the treaty of Granada (Nov. 1500) with Ferdinand II of Aragon for a partition of that kingdom, which was conquered in summer 1501; but a year later France and Spain were at war over the partition. Negotiating with Ferdinand's son-in-law Philip, ruler of the Netherlands, Louis concluded the treaty of Lyons (April 1503) whereby Naples would go to Philip's son Charles, fiancé of the French king's daughter Claude (1499-1524), heiress to Brittany. Ferdinand, however, adroitly disavowed this treaty; Louis kept his army near Rome in the summer of 1503, hoping that his favourite Georges d'Amboise (*q.v.*) would be elected pope; and by March 1504 the French had lost all Naples. By the treaty of Blois of Sept. 1504, Philip's father, the prospective Holy Roman emperor Maximilian I, recognized Louis as duke of Milan in return for a promise that Milan and also Burgundy should go to Charles and Claude on their marriage unless Louis should have a son; and by the treaty of Blois of Oct. 1505 Louis renounced his claim to Naples in favour of his niece Germaine de Foix, whom Ferdinand married. To save France from losing Claude's heritage, representatives of the three estates were assembled by Louis at Tours in May 1506 to insist on Claude's betrothal to his heir presumptive, Francis of Angoulême, instead of Charles.

Having crossed the Alps again to subdue a rebellion in Genoa,

Louis met Ferdinand at Savona in June 1507 to consolidate their new entente. Ferdinand and Pope Julius II adhered to the League of Cambrai, formed in Dec. 1508 for action by Louis and Maximilian against Venice; and on May 14, 1509, Louis won his great victory of Agnadello over the Venetians. In 1510, however, Julius turned against France. Louis retorted by sponsoring a general council of the Roman Catholic Church, to meet at Pisa in 1511; but Maximilian made a separate truce with Venice in April 1511, the pope, Spain and Venice formed their Holy league against France in October, and Henry VIII of England promptly joined it. The French victory at Ravenna in April 1512 proved fruitless, the Holy league's Swiss allies took Milan in the summer, and Maximilian joined the league in November. Louis secured an alliance with Venice and a truce with Ferdinand in spring 1513. But the French attack on Milan was defeated by the Swiss at Novara on June 6; Henry VIII won the battle of the Spurs, in Artois, on Aug. 16; and the Swiss invaded Burgundy in September. The Anglo-French peace of London (Aug. 1514) was cemented by the marriage of Louis, a widower since Jan. 1514, with Henry's sister Mary (see MARY [MARY TUDOR]) in October. Louis XII's overambitious Italian enterprises had ended in catastrophe. Diplomatically he had been outwitted twice by Ferdinand and once by Julius; and his doublecrossing of Maximilian over Claude's marriage had been repaid by Maximilian's final desertion of him.

In France itself Louis XII was highly popular: from the time of the assembly at Tours (1506), he was known as "the Father of the People." He simplified and improved the administration of justice (ordinance of March 1499); sought to protect his lowest subjects against oppression; financed his wars, up to 1509, without increase of direct taxation; and kept his kingdom free from civil war and, until the end of the reign, from invasion. His Gallican policy for the church was stiffened by the breach with Julius II. The theory of royal absolutism was sedulously promoted.

Louis XII died in Paris on Jan. 1, 1515, leaving two daughters: Claude and Renée (*q.v.*), later duchess of Ferrara.

LOUIS XIII (1601-1643), king of France from 1610, was born at Fontainebleau on Sept. 27, 1601, the eldest son of Henry IV of France by his second consort Marie de Médicis. On his father's assassination (May 14, 1610), Louis became king under his mother's regency. In pursuance of her policy of allying France with the Catholic Habsburgs, Marie arranged that Louis and his sister Elizabeth should marry the Spanish king Philip III's children, Anne of Austria and the future Philip IV of Spain respectively. These marriages were concluded in Nov. 1615. In France meanwhile the regency and the immediate period after the king's coming of age (1614), during which the queen mother continued to govern with the help of her favourite the marquis d'Ancre, were troubled by intrigues and civil war. In 1617 the king, resentful at being excluded from power, authorized the assassination of the marquis d'Ancre on the advice of his own favourite Charles d'Albert, later duc de Luynes. From then onward his relationship with his mother was one of ill-disguised or open hostility. (See further FRANCE: History.)

The decisive event for Louis XIII's life, private and public, was the entry of the cardinal duc de Richelieu, hitherto a partisan of Marie de Médicis, into the royal council in 1624. Thenceforward French policy was conducted by Richelieu. Yet nothing could be more mistaken than the traditional view of Louis as a feeble king dominated by an omnipotent minister. Poor in health, stuttering and timid, but prone to fits of violent rage, Louis was very conscious of his royal authority. Very religious, he felt himself responsible to God for all that was done in his name. Consequently it is in his personal psychology that the explanation of his relationship with Richelieu must be sought. Louis at first tolerated him, then gave him his confidence and his friendship; and, though subsequently he felt alarm at having given Richelieu so much power, he was yet convinced that no one else was working more effectively for the glory of his realm and so never allowed himself to be separated from the cardinal. Nevertheless, no important decision was taken without the king's consent. This as-

sociation of king and first minister constituted the regime sometimes described as the *ministériat*.

After the capture of La Rochelle from the Huguenots (1628), Louis XIII was forced to choose between two alternatives presented by Richelieu: an active and costly foreign policy or the internal rehabilitation of France. Louis chose the former. From that moment, internal policy was only a matter of securing, by empirical means, general obedience from the nobility, from the officials, from the *parlements* and from the tax-laden people. The royal finances and, above all, the treasury henceforth depended on tax farmers who made huge profits, while the peasantry, helpless against the consequences of bad harvests (as in 1631) and epidemics, led a life of constant hardship and sometimes of abject destitution.

Richelieu, vainglorious, grasping and convinced that ostentation upheld his authority, amassed a large personal fortune and lived in princely state. His foreign policy involved alliances with Protestant princes in Germany and, from 1635, an arduous war against Catholic Spain (see THIRTY YEARS' WAR). The need to alleviate the people's sufferings, Richelieu's own arrogance and the scandal of alliances with heretics were all a constant source of worry to Louis and might have prompted him to break with the cardinal. In Nov. 1630 the queen mother, who made herself the mouthpiece of the aggrieved nobility, nearly obtained the dismissal of Richelieu and the restoration to power of the pro-Spanish Catholic party headed by the brothers Michel and Louis de Marillac (the one keeper of the seals, the other a marshal of France); but from this crisis, known as the Day of Dupes, the minister's authority emerged all the stronger. The queen mother went into exile abroad—a course that her younger son Gaston, duc d'Orléans and the king's heir presumptive, had already taken.

The increasing challenge to the royal authority brought Louis round to Richelieu's merciless methods: stern examples were required to impress public opinion. When the duc de Montmorency (Henry II), governor of Languedoc, took up arms for the exiles and was captured in battle, Louis went to Toulouse during the trial of the rebel and refused to reprieve him on his being condemned to death (1632). In the war against Spain, neither the serious reverses of 1636 nor the subsequent difficulties deterred Louis from pursuing Richelieu's policy; but intrigues for peace with Spain flourished in circles around Anne of Austria and the king's confessor, Nicolas Caussin. To counter hostile influences, Richelieu took care to place people whom he could trust in the king's entourage, but he was mistaken in sponsoring the rise of the marquis de Cinq-Mars, the last of Louis XIII's youthful favourites. Cinq-Mars, flattered by the cardinal's enemies, involved himself in a conspiracy with the duc d'Orléans and Spain (1642); and at the same time Louis, wanting peace for the sake of his suffering people, began to view the cardinal with mistrust. Finally, however, the revelation of his favourite's treason brought Louis to rely more than ever on his minister. Moreover, Richelieu's work had borne fruit: the army, more obedient to the government than before, had not only put down the most dangerous peasant revolt, that of the Va-nu-pieds in Normandy (1639), but also had won solid successes against the Spaniards. The *parlements* and the clergy had been reduced to greater docility and the king of France was respected abroad as one of the most powerful kings in Europe. The birth of a dauphin, the future Louis XIV, in 1638 and of a second son, Philippe, later duc d'Orléans, in 1640, after the queen's long period of childlessness, precluded the danger of the crown's passing eventually to Gaston or to the house of Condé.

Louis XIII could thus suppose in the last months of his life that soon the victory of his armies would make possible an advantageous peace, so that he could devote himself to the relief of his subjects. Accordingly, when Richelieu died in Dec. 1642, he kept the cardinal's team of ministers in office; but Louis himself, having long been in ill health, died on May 14, 1643.

LOUIS XIV (1638–1715), king of France from 1643, was born at St. Germain-en-Laye on Sept. 5, 1638, the long-awaited first child of Louis XIII and Anne of Austria. The death of his father on May 14, 1643, made him king at the age of four, under the regency of his mother. Power lay in the hands of the regent and of her minister, Cardinal Mazarin, who had to face the last stages of the Thirty Years' War in Germany, the internal troubles of the Fronde and finally the continuation of the war with Spain that had begun in 1635. Though in 1651 the royal authority was so weak against the Frondeurs that the populace, inflamed by rumours of an intended flight of the government from Paris, was admitted to see the king in his bed, Mazarin nevertheless triumphed over his domestic and his foreign opponents: the Fronde was at an end by 1653, the peace of Westphalia (1648) and the peace of the Pyrenees (1659) marked the success of the arms and of the diplomacy of France. The peace of the Pyrenees was cemented by the marriage of Louis to his cousin, the infanta Marie Thérèse (Maria Teresa de Austria).

The Regime of Personal Government.—The king entered Paris in triumph in 1660. Mazarin died the next year; and the king, who since his coming of age in 1651 had left the control of affairs in Mazarin's hands, at once announced his intention of being his own first minister. He built up a thoroughly personal system of government and presided constantly over the council and many of its committees. Throughout the reign, policy was to be directed from the *conseil étroit* or *conseil d'état d'en haut* (upper council of state), to which the king summoned anyone whom he wished to consult, but which regularly comprised only a few men, who received the dignity of ministers of state. At the beginning of the king's personal reign these men were Michel Le Tellier, Hugues de Lionne and Nicolas Fouquet. Neither the chancellor nor all the secretaries of state (the effective ministers) were members of the upper council. After Fouquet's disgrace, Jean Baptiste Colbert took his place; and after Lionne's death in 1671, Le Tellier's son the marquis de Louvois entered the council. The ministers, however, were at the same time secretaries of state, and departmental specialization became firmly established. Louvois followed his father as secretary of state for war; the marquis de Pomponne (Simon Arnauld) succeeded Lionne in the foreign department, to be succeeded in turn by Charles Colbert de Croissy and by the latter's son Jean Baptiste, marquis de Torcy; and the great Colbert looked after the finances (as *contrôleur général*), the navy, the royal household and fine arts. No one ever held a predominant position, since Louis XIV detested the idea of a ministerial regime such as the cardinal duc de Richelieu had conducted. Diligent and constant in his attendance not only at the upper council of state, but also at the other councils (dispatches, finances, judicial affairs), the king was always the supreme and effective head of policy.

Imbued with the same sense of royal mission that his father had had, Louis also took a real pleasure in the exercise of the profession of king. Neither the queen mother nor the queen consort, neither the king's brother Philippe, duc d'Orléans, nor the dauphin, neither any of the princes of the blood nor any cardinal ever had any effective part in affairs, which were kept in the sole hands of the king and his ministers. In the eyes of the nobility, reduced to appointments at court or in the army, it was a reign of low, bourgeois government (*un règne de vile bourgeoisie*). The king's acknowledged mistresses, Louise de La Vallière and the marquise de Montespan, were allowed no secret influence on policy, despite the rank accorded to them and the unparalleled honours granted to their children (some of whom were not only legitimized but even included among the princes of the blood). On the other hand the marquise de Maintenon, whose marriage to the king took place in secret at an unknown date (probably in autumn 1683) and who had no status at court except that of a friend enjoying the king's confidence, may have exerted some influence on decisions, since her intelligence and experience led Louis frequently to ask for her advice; but her tact and her prudence were such that no trace of this influence can be convincingly shown.

The Glory of the Monarchy.—Did Louis XIV, in his personal

rule, adhere to a definite political program? If a general theme characterizing the reign had to be discerned, it would consist essentially of the pursuit of the king's glory. This does not mean that Louis XIV was exclusively concerned to win glory by war: he was attentive to anything that could enhance the brilliance of his reign. He rightly valued the zeal of ministers who reformed the internal administration, reduced the sovereign courts, representative assemblies and municipal bodies to obedience, encouraged industry, secured discipline in the army, built up the navy and, by patronage, stimulated a spirit of competition among writers and artists. Making himself the patron of French classicism, Louis personally encouraged the greatest writers of the time, such as Molière, Boileau and Racine, though his own tastes inclined him rather toward the court ballet and the opera, to which his protégé Jean Baptiste Lully (a naturalized Italian) gave a French air. Passionately fond of building, Louis saw to the completion of the Louvre and to the building of Versailles (with constant modifications), Les Invalides and Marly-le-Roi. Regarded by Louis from 1661 as the ideal place for holding his magnificent fêtes (which might last for several days at a time), Versailles became in 1685 the permanent seat of the king and the court. Fontainebleau during the hunting season and the charming château of Marly-le-Roi, exemplifying a refinement in the royal taste for beautiful houses, served for amusements. Court life, ruled by meticulous etiquette, had no meaning except to enhance the king's prestige, both in France and abroad.

Foreign Policy.—Louis XIV's desire for unrivaled power guided his foreign policy. There can be no doubt that he wanted to become the foremost prince in Europe. Envyng Leopold I's imperial dignity, he even aspired to be Holy Roman emperor himself some day. Meanwhile he set to work to achieve the final ruin of Spanish power and to turn the German and Italian princes and the English king Charles II into subsidized dependents of France.

After the death of his father-in-law Philip IV of Spain (1665), Louis in his queen consort's name undertook the War of Devolution (1667–68); and the treaty of Aix-la-Chapelle gave him several strategically important towns in the Spanish Netherlands. He then decided on a punitive expedition against the United Provinces of the Netherlands, whose commercial rivalry with France and whose republican politics seemed intolerable to him (1672). Winning a rapid victory, he overreached himself in the negotiations for peace by making his demands too stringent and soon had to face a coalition that brought Spain and the emperor Leopold I into the war against him. Even so he pursued hostilities successfully until 1678, when he stopped them in time to prevent Great Britain's joining the coalition. The treaties of Nijmegen (1678–79) gave him new territory in the Spanish Netherlands and Franche-Comté. Now at the peak of his power, the king received the title of "Louis the Great" from the Hôtel de Ville of Paris (1680). (See DUTCH WARS.)

The king's next step was to set up the so-called *chambres de réunion* to furnish juridical grounds for the annexation of all territories which had in earlier times been dependencies of territories now French. Under this system not only Alsace but also other extensive areas on the left bank of the Rhine were to be severed from the Holy Roman empire. Then, in 1681, Louis seized Strasbourg on the Rhine frontier and Casale in Montferrat south of the Alps. In the same year he also attacked Luxembourg, to effect a "reunion"; and after interruption and resumption of warfare in 1682–83 that fortress also fell to the French in 1684. The armistice of Regensburg (1684) between France and the empire accorded to Louis possession for 20 years of Strasbourg, Luxembourg and all territories "reunited" to France before Aug. 1681.

Changes, however, had already taken place in Europe, of which neither Louis nor his ministers had taken the measure. German public opinion, irritated by his tyrannous aggression, could be worked up against him: southern Germany escaped from his influence after the death of the elector Ferdinand Maria of Bavaria (1679) and inclined once more toward the Austrian Habsburgs, whose prestige rose through the breaking of the Turkish siege of Vienna (1683) and the reconquest of Hungary; and in northern

Germany the rising power of Brandenburg, which had formerly been one of France's client states, became an adversary after the revocation of the Edict of Nantes (see below). In England, strengthened by an expanding economy, parliament and nation condemned the francophile policy of the Stuart kings; and the revolution of 1688 put Louis XIV's implacable enemy, William III of Orange, on the English throne. Thus the era of the great coalitions against France began. The League of Augsburg (1686) was followed in 1689 by a far more formidable combination which, in the War of the Grand Alliance, convinced Louis that he would have to renounce the greater part of what had been claimed under the program of "reunions" if he was to conserve his most important gains, notably Alsace (peace of Rijswijk, 1697). He accordingly gave up the idea of French hegemony in Europe and resigned himself to preserving the balance of power. All the same, he was unable to obtain general agreement among the powers for an equitable division of the Spanish inheritance at the death of the childless Charles II of Spain. Charles II's last will named as his heir Philippe, duc d'Anjou (see PHILIP V of Spain), who was a grandson of Louis XIV but was apparently precluded from the direct line of succession to the French throne by his elder brother and the latter's son. Hoping to preserve the peace of Europe, Louis XIV accepted this will (1700), but there ensued the most terrible war of the reign (see SPANISH SUCCESSION, WAR OF THE). Louis sustained this long war with courage and wisdom; and the peace treaties of Utrecht and Rastatt (1713, 1714), though they reduced the territory of France a little, yet allowed him to keep the essential acquisitions.

Religious Affairs.—Louis XIV, proud of his title of "most Christian king," was resolute in protecting the Catholic religion. He himself was faithful to it, despite the irregularities of his private life. Though the French Protestants were now docile subjects, he made it a matter of principle to withhold both his favour and even their rights under ordinary justice from them. The Edict of Nantes was applied in accordance with a strictly literal interpretation of its clauses; and to please the king an odious system of petty persecution was set afoot, resulting in servile conversions on the one hand or in the voluntary exile of the most steadfast Protestants on the other. Finally, in 1685, by the Edict of Fontainebleau, Louis revoked the Edict of Nantes, and Protestantism was no longer tolerated in France. The Protestant revolt of the Camisards, in reaction against this treatment, aggravated the troubles of the kingdom during the War of the Spanish Succession.

In the Catholic Church itself there were other problems. As all resistance to royal decisions was regarded as tending toward rebellion, Louis XIV let himself be persuaded that Jansenism was a dangerous opinion which had to be suppressed. The community at Port Royal, a rallying point for the so-called Jansenists, was subjected to intermittent persecution; and after a temporary lull in the controversy Louis obtained the bull *Vineam Domini* (1705) from Pope Clement XI. As the nuns at Port Royal would not accept this bull without reservations, Louis in 1709 had their community dispersed; and in 1713 he obtained an even more forceful condemnation of Jansenism in the bull *Unigenitus*. Another opinion, Quietism, was likewise condemned, mainly through the influence of Bossuet, despite Fénelon's defense of certain Quietists.

Meanwhile, however, notwithstanding his zeal against Protestants, Jansenists and Quietists, Louis had been involved in grave quarrels with two popes. In 1664 he threatened war against Alexander VII because of disrespect to the French ambassador in Rome, François de Créquy, by the pope's Corsican guard. A long dispute with Innocent XI about the extension of the *régale* or royal right of appointment to benefices led in 1681 to the convening of an assembly of the Gallican Church to settle the question; and in 1682 this assembly proceeded to formulate the famous "Four Articles," which made such a challenge to the pope's jurisdiction that France seemed on the brink of schism from Rome. Not until 1693 did Louis abandon these articles, forced to do so by the general situation.

Little able to judge for himself in doctrinal controversies, Louis

above all looked for obedience and unity among his subjects in matters of faith as in all else. The policy that he sponsored provoked the growth of opposition and the spread of unbelief.

The Conclusion of the Reign.—When Louis, duc de Bourgogne (1682–1712), eldest son of the dauphin Louis (1661–1711), reached his majority, Louis XIV proudly remarked that hitherto in France, no one had ever seen father, son and grandson all of age together and that the danger of a minority was averted for a long time. Yet when the king died, at Versailles on Sept. 1, 1715, death had already removed the two intermediate generations, and the heir to the old king was his five-year-old great-grandson, Louis XV, third and only surviving son of the duc de Bourgogne. Great sadness had clouded the last years of the reign and Louis XIV was little regretted by his subjects.

Voltaire extolled the reign in his *Siècle de Louis XIV* (1751); and later historians have variously appreciated a man and a regime which, in the difficult circumstances of the times, through wars and economic crises, yet made a great contribution to the progress and grandeur of France in Europe as well as to the lasting prestige of the French nation.

Church (ed.), *The Greatness of Louis XIV: Myth or Reality?* (1959) and W. H. Lewis, *Louis XIV* (1959). (V. L. T.)

LOUIS XV (1710–1774), king of France from 1715 to 1774, was born at Versailles on Feb. 15, 1710, the great-grandson of Louis XIV and the third son of Louis, duc de Bourgogne, and Marie Adélaïde of Savoy. His parents and his only surviving brother having all died in 1712, he became king at the age of five on Louis XIV's death (Sept. 1, 1715). Until he attained his legal majority in Feb. 1723 France was governed by Philippe, duc d'Orléans, as regent. At first the child's delicate health made it seem unlikely that he would live long. In his infancy he was educated by his governess, the duchesse de Ventadour (C. E. M. de La Mothe-Houdancourt), and after 1714 by his tutor, the bishop of Fréjus, the future cardinal André Hercule de Fleury. He was betrothed in 1721 to the infanta Mariana, daughter of his uncle Philip V of Spain, and in Oct. 1722, five months before his majority, he was consecrated king at Reims.

After the death of the duc d'Orléans (1723), Louis took as his premier minister Louis Henri, duc de Bourbon. During this administration the Spanish betrothal was canceled, and the king was married in Sept. 1725 to Marie Leszczyńska, daughter of the dispossessed Stanislaw I of Poland. A well-educated, pious and charitable woman but plain in appearance and nearly seven years her husband's senior, she was to bear him two sons and seven daughters. When Fleury had taken Bourbon's place as premier minister (1726), the dynastic connection with Poland led to French intervention in the War of the Polish Succession in 1733. France intervened nominally in support of the claims of Louis XV's father-in-law but really in order to secure, as compensation for the loss of Poland, the transfer of the duchy of Lorraine to Stanislaw and its eventual reversion to France through Marie. This provision was agreed to by Austria in the preliminary peace treaty of Vienna (Oct. 1735), so that when Stanislaw died in 1766 Lorraine came effectively under French sovereignty.

Louis XV's personal influence on French policy became perceptible only after Fleury's death (Jan. 1743). His first major decision was to announce that henceforth he would have no premier minister. Theoretically, this should have meant that the business

of the central government would be conducted, as under Louis XIV, between the king and each secretary of state or departmental minister and that the co-ordination of policy would be left, not to the royal council, but to the king himself. Unfortunately, Louis had neither the energy nor the sense of duty requisite for the performance of such a task. Handsome, intelligent, devoted to his children and courageous on the field of battle, he was yet timid and lacking in self-confidence as a ruler, morbid in his personal fancies, a slave to his passions and a religious bigot. Indifferent to his subjects' welfare, he kept himself increasingly isolated at court, where he sought relief from oppressive etiquette and administrative routine in hunting and sensual excesses. Consequently the authority of the royal council was undermined, no firm direction was given to national policy and the ministers themselves, while attempting to dominate, often became the victims of court factions and intrigue.

Because Louis rapidly degenerated into a *roi fainéant*, ambitious generals and ministers were induced to press their claims to advancement or political predominance through the royal mistresses. Though the influence of the latter never amounted to "petticoat government," as has often been supposed, it did contribute further to establish the rule of court factions. Pauline de Mailly-Nesle, marquise de Vintimille, who was the king's mistress from 1739 to 1741, sponsored the anti-Austrian court faction led by the future marshal de Belle-Isle, which prepared French intervention in the War of the Austrian Succession, despite previous French acceptance of the Holy Roman emperor Charles VI's Pragmatic Sanction. Her sister Marie, duchesse de Châteauroux, who was the king's mistress between 1742 and her death in Dec. 1744, backed the designs of the duc de Richelieu (L. F. A. du Plessis) to succeed to the political influence of Fleury. The most celebrated of these "political" mistresses, the marquise de Pompadour, whose influence over the king lasted from Sept. 1745 till her death in April 1764, was a staunch protector of the literary clique of the *Encyclopédistes* and a supporter of Louis' other powerful minister, the duc de Choiseul. The comtesse du Barry, last of the king's favourites, apart from contributing to the dismissal of Choiseul in 1770, exercised little or no political influence.

The king's interest in Polish affairs and his wish to influence directly the course of foreign affairs were at the root of his system of "secret diplomacy," the so-called *secret du roi*. The original object of this, from 1743 onward, was to promote the candidature of Louis François de Bourbon, prince de Conti, to the elective Polish throne by means of secret agents maintained by the king in various European capitals. From 1752 the head of this unofficial network of diplomacy was Charles François, comte de Broglie, French ambassador to Poland. The king's personal policy in foreign affairs was often at variance with that conducted by his official advisers, who remained for the most part ignorant of its details and objectives. In general, this secret diplomacy aimed at maintaining the waning strength of France's traditional allies in northern and eastern Europe, namely Sweden, Poland and Turkey; but the incoherence of French official and secret diplomacy was seen at its worst in 1772, when Prussia, Austria and Russia were able to partition Poland and virtually to eliminate French influence in central Europe. The existence of the *secret du roi* had meanwhile become well known to foreign powers: it was used by the Austrian statesman Wenzel Anton von Kaunitz, in his initial secret overtures to the French court, which culminated in the conclusion of the Franco-Austrian treaties of alliance of May 1756 and May 1757 after Prussia, which had previously been France's traditional enemy, Great Britain. This reversal of alliances or diplomatic revolution was largely the product of the inertness of French official foreign policy between 1748 and 1756, resulting from the king's subordination of the ministry of foreign affairs to his secret agents. It did not redound to the French advantage in the ensuing Seven Years' War, since it bound the government to unprofitable continental commitments during the crucial maritime and colonial struggle with Great Britain and made it harder to maintain French influence in Turkey. The loss of most of the French possessions in Canada and India followed.

During the later years of Louis XV's reign an attempt was made to strengthen the waning authority of the crown by withdrawing from the *parlements* the privilege of obstructing royal legislation. This privilege, suspended by Louis XIV, had been restored to the *parlements* during the regency. The judicial magistrates had later consolidated their position as opponents of the crown by claiming, in the absence of the estates-general, to be defenders of the fundamental laws of the kingdom and by uniting the provincial *parlements* in a close union with the *parlement* of Paris. In this way they had overthrown the financial system of John Law, had helped to procure the expulsion of the Jesuits in 1764 and had, for a time, disrupted the provincial administration of Brittany. The *parlements* also stood resolutely in the way of financial reform. In 1771 the chancellor, René de Maupeou, determined to strike at this abuse by restricting the *parlement* of Paris to purely judicial functions and by abolishing the sale of judicial offices. Despite some popular opposition, the new judicial system functioned effectively till the king's death and might have saved the Bourbon monarchy from the path that led to revolution if his successor had not gratuitously abandoned the reform. Apart from this reform, Louis XV's long reign had been marked by a decline in the crown's moral and political authority and by reverses in foreign and military affairs. Popular in his youth as "Louis the Well-Beloved," the king died at Versailles on May 10, 1774, hated as much as Louis XIV had been.

LOUIS XVI (1754-1793), king of France from 1774, was born at Versailles on Aug. 23, 1754, the third son of the dauphin Louis and his consort Maria Josepha of Saxony. At first known as the duc de Berry, he became the heir to the throne on his father's death in 1765, since his second elder brother had died in 1754 and his eldest brother in 1761. His education was entrusted to the duc de La Vauguyon (Antoine de Quélén de Caussade), who made little effort to ensure that he should be properly trained for his responsibilities. Louis nevertheless possessed an excellent memory, acquired a sound knowledge of Latin and English and took an interest in history and geography. In 1770 he married the Austrian archduchess Marie Antoinette (q.v.), daughter of Maria Theresa and the Holy Roman emperor Francis I.

On the death of his grandfather Louis XV, Louis succeeded to the French throne on May 10, 1774. At that time he was still immature, lacking in self-confidence, austere in manner and, because of a physical defect (later remedied by an operation), frigid in his relations with his young wife. Well-disposed toward his subjects and interested in the conduct of foreign policy, Louis had not sufficient strength of character or power of decision to combat the influence of court faction or to give the necessary support to reforming ministers, such as Turgot or Necker, in their efforts to give greater stability to the tottering finances of the *ancien régime*. The prestige of the monarchy was also compromised early in his reign by the decision in Aug. 1774 to restore the political powers of the *parlements*, which had been withdrawn in 1771. Louis XVI's reign before 1789 coincided with the increasing strength of the aristocratic reaction. It was aristocratic opposition to the fiscal, economic and administrative reforms of the controller general of finance, Calonne, in 1787 that forced the king, in July 1788, to summon the estates-general for the following year and thus led to the Revolution (see FRANCE: History; FRENCH REVOLUTION).

After 1789 Louis XVI's incapacity to rule, his irresolution and his surrender to reactionary influences at court were partially responsible for the failure to establish in France the forms of a limited constitutional monarchy. Louis had at first rightly regarded the Revolution as the product of an aristocratic Fronde and should, therefore, have grasped the opportunity of forming an alliance between the crown and the middle-class reformers in the Constituent Assembly. Instead he allowed himself, in the

spring of 1789, to be dominated by the reactionary clique surrounding his younger brother Charles, comte d'Artois (see CHARLES X, king of France), and to be converted to the policy of defending the privileges of the clergy and nobility. He continued to believe, even after the increasingly radical trend of popular movements in Paris and the provinces had demonstrated the futility of such hopes, that the Revolution would burn itself out.

By this time the fundamental weakness of the king's character had become evident: lethargic in temperament, lacking political insight and therefore incapable of appreciating the need to compromise, Louis continued to practise his personal hobbies (making locks and doing a little masonry) and to offset his overindulgence in food and drink by hunting. He dismissed Necker in early July 1789 and showed his reluctance to sanction the Declaration of the Rights of Man and the destruction of the feudal regime in August. His resistance to popular demands was one of the causes of the forcible transfer of the royal family from Versailles to Paris on Oct. 6. Yet he made still more mistakes, refusing to follow the secret advice tendered to him after May 1790 by Mirabeau, abdicating his responsibilities and acquiescing in the disastrous attempt to escape from the capital to the eastern frontier on June 20, 1791. Caught at Varennes and brought back to Paris, he seems thenceforward to have been completely dominated by the queen, on whom must accordingly fall the chief blame for the court's subsequent political duplicity and outright treason.

From the autumn of 1791 the king tied his hopes of political salvation to the dubious prospects of foreign intervention. At the same time he encouraged J. P. Brissot's policy of war with Austria in the expectation that French military disaster would pave the way for the restoration of his authority as the reward for his mediation with the Austrians. Prompted by Marie Antoinette, Louis rejected the advice of the moderate constitutionalists, led by Antoine Barnave, loyally to implement the constitution of 1791, which he had sworn to maintain, and committed himself to a policy of subterfuge and deception. The outbreak of the war with Austria in April 1792, the suspected machinations of the queen's "Austrian committee" and the publication of the manifesto by the duke of Brunswick threatening the destruction of Paris if the safety of the royal family were again endangered led to the capture of the Tuileries palace by the people of Paris and the provincial *fédérés* on Aug. 10, 1792. It also led to the temporary suspension of the king's powers by the Legislative Assembly and the proclamation by the Convention of the first French republic on Sept. 21. Proof of Louis XVI's secret dealings with Mirabeau and of his counterrevolutionary intrigues with the foreigners were forthcoming in Nov. 1792, after the discovery of incriminating evidence in the Tuileries. On Dec. 3 it was decided that Louis, who together with his family had been imprisoned in the Temple since August, should be brought to trial for treason. He himself appeared twice before the Convention (Dec. 11 and 23). Despite the last-minute efforts of the Girondins to save him, Citizen Capet, as he was then called, was found guilty by the Convention and condemned to death on Jan. 18, 1793, by 387 votes (including 26 in favour of a debate on the possibility of postponing execution) against 334 (including 13 for a death sentence with the proviso that it should be suspended). When a final decision on the question of a respite was taken on Jan. 19, Louis was condemned to death by 380 votes against 310. He was guillotined in the Place de la Révolution in Paris on Jan. 21, 1793.

Louis XVI's courage on June 20, 1792, when the royal palace was invaded by the Paris mob after his dismissal of the Girondin ministry, and his dignified bearing during his trial and at the moment of execution did something to redeem, but did not re-establish, his reputation. He was unfitted by temperament and education for the duties of kingship and he never responded to the challenge of the liberal and democratic forces in France. As he never understood those forces, he feebly attempted first to resist and then to betray the Revolution, which might well, as Mirabeau had seen, have consolidated the royal authority.

LOUIS XVII (1785-1795?), titular king of France from 1793, was born at Versailles on March 27, 1785, the second son of Louis XVI and Marie Antoinette. Baptized as Louis Charles, he bore the title of duc de Normandie until he became dauphin on the death of his elder brother, Louis Joseph, on June 4, 1789. A delicate child, he was frequently ill. On the suspension of the monarchy after Aug. 10, 1792 (see FRANCE: History; FRENCH REVOLUTION), he was imprisoned with the rest of the royal family in the Temple in Paris. Louis XVI was beheaded on Jan. 21, 1793, whereupon the royalists acknowledged his son as king of France.

On July 3, 1793, Louis XVII was taken from his mother: the Paris commune feared royalist attempts to rescue this valuable hostage; and in any case the trial of Marie Antoinette was about to begin. The commune put Louis under the surveillance of a cobbler, Antoine Simon, who treated Louis as a child of the people but cannot be shown to have been positively cruel to him.

On Oct. 6, 1793, P. G. Chaumette and J. R. Hébert, with some other commissioners of the Paris commune, came to interrogate Louis and tried to extract infamous accusations against his mother from him. Next day, Louis saw his sister Marie Thérèse (the future duchesse d'Angoulême) for the last time. On Oct. 16, Marie Antoinette was guillotined.

On Jan. 5, 1794, Simon resigned the custody of Louis XVII, and on Jan. 16 the commune decided that Louis XVII should have a guard of four commissioners, to be renewed daily. This arrangement took effect from Jan. 19. Louis was kept alone in one room, his food being passed to him through a turnbox. On July 28, the day after the fall of Robespierre, Barras went to see him. Recognizing that the child was ill, Barras sent P. J. Desault, chief doctor at the Hôtel Dieu, to see him and appointed a new warder, the Martiniquais J. J. C. Laurent. During the night of Oct. 28 a surprise inspection of the Temple was made by two members of the committee of general security; and the appointment (Nov. 8) of a man called Gomin to assist Laurent seems to have been the consequence of this visit. On Dec. 19 there was an inspection by J. B. Harmand (de la Meuse), J. B. C. Mathieu and J. Reverchon, who found the dauphin ill with a tumour on his elbow. On Jan. 22, 1795, Cambacérès asked the Convention to decide whether Louis and his sister should be kept in prison or expelled from French territory. He himself favoured the former alternative, which the Convention adopted.

On March 31, 1795, Laurent was replaced by Étienne Lasne, a house painter. In May, Lasne and Gomin warned the committee of general security that "the Capet child" was gravely ill. At that time peace talks were going on with Spain and the idea of exchanging Louis XVI's children for the members of the Convention who were prisoners of Austria had been envisaged. Desault, sent to the Temple on May 6, found Louis extremely weak and unresponsive and began to tend him conscientiously, but suddenly died himself on June 1. He was replaced by P. J. Pelletan, chief surgeon at the Humanité hospital, who first visited Louis on June 6 and had him moved to the smaller tower so that he should get more light and air. Louis XVII died, however, on June 8, 1795. An inquest on June 9 having established that the child, "of about ten years of age," had died of scrofula, he was buried on June 10 in the cemetery of Ste. Marguerite, with nothing to mark the site of his grave.

The secrecy surrounding the last months of Louis XVII's life naturally gave rise to rumours: some said that he was not dead but had escaped from the Temple, others that he had been poisoned. The theory of an escape was first put forward in London by a Chouan, Joseph de Puisaye, as early as Oct. 1794. It was passed on by Yves Cormier to Lady Atkyns (née Charlotte Walpole; d. 1836), who convinced herself of its truth. It was then given wide currency by J. J. Regnault-Warin's novel *Le Cimetière de la Madeleine* (1800-01), according to which the dauphin was handed over to the Chouans and another child substituted for him in the Temple. This climate of opinion produced numerous false dauphins or pretenders: J. M. Hervagault in 1798, Mathurin

Bruneau in 1815, the baron de Richemont (H. E. L. V. Hébert) in 1828 and more than 30 others, of whom the chief was K. W. Naundorff (q.v.). A vast literature grew up on the subject, culminating in the foundation of a monthly *Revue historique de la question Louis XVII* (1905).

There is no real evidence for the theory of poisoning. Louis Hastier (see below, *Bibliography*) argues that Louis XVII died in the Temple in Jan. 1794 and was then replaced by another child (who died in turn on June 8, 1795); but the evidence adduced for this theory does not stand up to critical examination.

LOUIS XVIII (1755-1824), king of France by title from 1795 and in fact from 1814 (except for the interruption of the Hundred Days), was born at Versailles on Nov. 17, 1755, the fourth son of the dauphin Louis (son of Louis XV) and Maria Josepha of Saxony. He received the names Louis Stanislas Xavier and the title comte de Provence. His education was supervised by the devout duc de La Vauguyon (Antoine de Quélen de Causade), but his own taste was for the writings of Voltaire and the *Encyclopédistes*. He was married on May 14, 1771, to Louise Marie Joséphine of Savoy.

The dauphin's two eldest sons, Louis duc de Bourgogne and Louis duc d'Aquitaine, had died in 1761 and 1754 respectively, and the dauphin himself died in 1765. Consequently the surviving elder brother of the comte de Provence became king as Louis XVI when his grandfather died in 1774. The comte de Provence then had the style Monsieur, as the elder of the king's two brothers, and as long as Louis XVI remained without male issue, Monsieur was heir presumptive to the crown. He courted popularity and took an active part in politics, but the birth of a dauphin in 1781 followed by that of the future Louis XVII in 1785, was a blow to his ambitions. He opposed the revival of the *parlements* (1774), wrote a number of political pamphlets, and at the Assembly of Notables (1787) presided, like the other princes of the blood, over a bureau, to which was given the name of the *Comité des sages*; he also advocated the double representation of the tiers état in the estates-general convened for 1789. At the same time he cultivated literature, entertaining poets and writers both at the Luxembourg and at his château of Brunoy and gaining a reputation for wit in the salon of his mistress, the comtesse de Balbi (Anne de Caumont-La Force). When the French Revolution began, he did not emigrate immediately after the taking of the Bastille but, possibly from motives of ambition, remained in Paris. In June 1791, however, at the time of Louis XVI's flight to Varennes, he also fled (by a different route) and, in company with the comte d'Artois (Antoine Louis François de Bésiadre, who later replaced Madame de Balbi as his confidant and largely influenced his policy), reached Brussels. There he joined his younger brother the comte d'Artois, later Charles X of France.

Proceeding to Coblenz, Monsieur put himself at the head of the counterrevolutionary *émigrés* there and set himself up in royal Europe, appointing ambassadors and soliciting help from the European sovereigns, especially from Catherine II of Russia. Prompted by the comte d'Artois and by the former minister Calonne, he pursued an entirely selfish policy without regard to the situation of Louis XVI and Marie Antoinette in Paris: he obstructed the representatives of the king and queen and issued uncompromising manifestoes (such as those of Sept. 1791 and Aug. 1792). After the French victory at the battle of Valmy (Sept. 1792) he had to retire to Hamm in Westphalia, where, on the death of Louis XVI (Jan. 1793), he proclaimed himself regent. He then went south with the idea of encouraging the royalist feeling in the south of France and settled at Verona, where on the death of Louis XVII (June 8, 1795) he took the title of Louis XVIII.

From this time until 1814 the story of Louis XVIII's life is a record of constant wanderings, negotiations and conspiracies. In April 1796 he joined Condé's army on the German frontier, but shortly afterward he was requested to leave the district and accepted the hospitality of the duke of Brunswick at Blanckenberg till late in 1797. Then the Russian emperor Paul I permitted him to settle at Mittau in Courland, where he stayed till 1801. All this time he was in close communication with the royalists in France, but was much embarrassed by the conflicting policy pursued by the comte d'Artois from England and was largely at the mercy of corrupt and dishonest agents. At Mittau in 1799 he realized his cherished plan of marrying Madame Royale (Thérèse de France, daughter of Louis XVI) to the duc d'Angoulême, elder son of the comte d'Artois. From Mittau, too, was sent his letter to Napoleon Bonaparte (1800) calling on him to use his power to restore the Bourbons—a proposal contemptuously refused. Louis in turn declined to accept a pension from Bonaparte and later, in 1803, though his fortunes were at their lowest ebb, refused to abdicate at his suggestion and accept an indemnity.

Suddenly expelled from Mittau in 1801 by the capricious Paul I, Louis made his way, in the depth of winter, to Warsaw, where he stayed for three years. All this time he was trying to convert France to the royalist cause, and had a *conseil royal* in Paris, founded at the end of 1799 by Pierre Paul Royer-Collard, the abbé Montesquiou, and the marquis de Clermont-Gallerande, but after 1800, and still more after Napoleon's assumption of the title of emperor (May 1804), the royal cause appeared hopeless. In Oct. 1804 Louis met the comte d'Artois at Calmar in Sweden, whence they issued a protest against Napoleon's action. Warned that he must not return to Poland, Louis gained permission from the new tsar Alexander I again to retire to Mittau. After the treaty of Tilsit (1807), however, he was again forced to depart, and took refuge in England, where he stayed first at Gosfield in Essex, then, from 1809, at Hartwell in Buckinghamshire. In 1810 his wife died. When Avaray died (1811), Louis took the equally intransigent but abler Pierre Louis Casimir, comte de Blacas, as his favourite.

After Napoleon's defeats in 1813 the hopes of the royalists revived, and Louis issued a fresh manifesto in which he promised to recognize some results of the Revolution. Negotiations were also opened with Bernadotte (see CHARLES XIV John, King of Sweden and Norway), who seemed willing to support his cause, but was really playing for his own hand. In March 1814 the allies entered Paris, and thanks to Talleyrand's negotiations the restoration of the Bourbons was effected. Louis XVIII entered Paris on May 3, 1814, after issuing the declaration of St. Ouen (May 2), in which he promised to grant the nation a constitution. He did this on June 4 by his *Charte constitutionnelle*.

Louis XVIII was now nearly 60, wearied by adversity and a sufferer from gout and obesity. But though clear-sighted, widely read and a good diplomatist, his impressionable and sentimental nature made him too subject to personal and family influences. His concessions to the reactionary and clerical party of the *émigrés*, headed by the comte d'Artois and the duchesse d'Angoulême, aroused suspicions of his loyalty to the constitution, the creation of his "military household" alienated the army, and the constant presence of Blacas made the formation of a united ministry impossible. After the Hundred Days, when Napoleon's return to France (March 1815) forced Louis to flee to Ghent, the dismissal of Blacas was made one of the conditions of his second restoration. On July 8, 1815, he again entered Paris, "in the baggage train of the allied armies," as his enemies said, but in spite of this he was received with the greatest enthusiasm by a people weary of wars and looking for constitutional government. He was forced to retain Talleyrand and Fouché in his first ministry, but rid himself of them when the elections of 1815 assured him of a strong royalist majority in the chamber (the *chambre introuvable*, a name given it by Louis himself). At this time he came into contact with the young Élie Decazes (q.v.), prefect of the police under Fouché, who now became his favourite. Having obtained a ministry he could trust, with the duc de Richelieu at its head and Decazes as minister of police, the king gave it his

loyal support and did his best to shield his ministers from attacks by the royal family. In Sept. 1816, alarmed at the violence of the *chambre introuvable*, he was persuaded by Decazes to dissolve it. The Ultras (extreme royalists) failed in an attempt to regain their ascendancy over the king by conniving at the sudden return of Blacas from Rome to Paris.

The king's policy throughout was one of prudence and common sense. While Decazes was in power, the king's policy to a large extent followed his and was rather liberal and moderate. But after the assassination of his nephew the duc de Berry (1820), Louis saw that Decazes, who had been president of the council since Nov. 1819, could no longer carry on the government, and sorrowfully acquiesced in his departure. He then transferred his support to Richelieu, the head of the new ministry.

In the absence of Decazes a new favourite was found to amuse the king's old age, the comtesse du Cayla (Zoé Talon), a protégée of the vicomte Sosthène de La Rochefoucauld and consequently a creature of the Ultras. As the king became more and more infirm, his power of resistance to the intrigues of the Ultras became weaker. The birth of a posthumous son to the duc de Berry (Sept. 1820), and the resignation of Richelieu (1821), left him entirely in their hands, and after Villèle had formed a ministry of an ultra-royalist character, the comte d'Artois was associated with the government, which passed more and more out of the king's hands. The power of the Ultras was further strengthened by the success of the French military intervention in Spain in favour of Ferdinand VII and the absolutist party. Complete control over the chambers was brought about by the creation of 27 new Ultra peers and by the results of the general election of 1824, which produced in the chamber of deputies so strong a royalist majority that Louis, recalling the *chambre introuvable*, named it the *chambre retrouvée*.

Louis XVIII died at the Tuileries, in Paris, on Sept. 16, 1824. He had the Bourbon characteristics, their love of power, a certain nobility of demeanour and a great consciousness of dignity. He also showed tenacity of purpose during his exile and patience during the illness which preceded his death. But he was cold, unsympathetic and calculating, and had always greatly coveted the crown. He had a talent for intrigue, to which was added an excellent memory and a ready wit.

Louis XVIII's *Relation d'un voyage à Bruxelles et à Coblenz, 1791* was published in 1822. Some of his letters are contained in special collections such as *Lettres et instructions de Louis XVIII au comte de Saint-Priest*, edited by P. B. de Barante (1845); *Lettres d'Artwell: correspondance politique et privée de Louis XVIII*, addressed to Avaray (1880); and *Correspondance inédite du prince de Talleyrand et du roi Louis XVIII pendant le congrès de Vienne*, edited by M. G. Pallain (1881; Eng. trans. 1881).

(G. DE B. DE S.)

LOUIS I THE GREAT (1326–1382), king of Hungary from 1342 and of Poland from 1370, was born on March 5, 1326, the third son of Charles I of Hungary (Charles Robert or Carobert of Anjou-Naples) and Elizabeth, daughter of Wladyslaw I of Poland. Crowned king of Hungary in succession to his father on July 21, 1342, he was concerned for the greater part of his reign with Italian affairs, fighting against Venice for control of the Adriatic sea-board and against the Neapolitans for dynastic reasons. In 1346 he was defeated by the Venetians at Zara (Zadar), that city having put itself under Hungarian protection. Then in 1347 he led an expedition against the kingdom of Naples: his younger brother Andrew, consort of his second cousin Queen Joan I (q.v.) had been murdered there in 1345; and Joan had subsequently married another cousin, Louis of Taranto, a suspected accomplice in the murder. Though Louis of Hungary occupied Naples in 1348, he soon had to retire; a new invasion (1350) also came to nothing, though he was most unwilling to ratify the peace of 1352.

In 1353 Louis married Elizabeth, daughter of Stjepan Kotro-

manic of Bosnia. He next succeeded in forming, in 1357, a great league against the Venetians, who were forced to cede most of the Dalmatian towns to Hungary (treaty of Zara, Feb. 1358).

In central Europe, meanwhile, Louis maintained generally friendly relations with the Habsburgs (differences with Rudolf IV of Austria were peacefully composed at meetings in 1360) and cordial relations with his maternal uncle Casimir III of Poland. The latter, being childless, designated Louis as his successor; and after Casimir's death Louis was crowned king of Poland (Nov. 17, 1370). The Poles, however, never let him exert much real authority over them, though in 1374 he forced them to recognize his infant daughter Maria (*see below*) and her betrothed husband Sigismund of Luxembourg as their future queen and king.

Louis took little action against the growing Turkish threat to Hungary. Instead he reverted to his Italian concerns. When the papal schism of 1378 broke out, he helped his protégé Charles of Durazzo (*see CHARLES III*) to supplant Joan of Naples, after she had mistakenly declared herself for the antipope Clement VII; and at the same time he undertook a third war against Venice. This ended with the treaty of Turin (Aug. 18, 1381), whereby Venice virtually ceded Dalmatia and promised an annual tribute of 7,000 ducats to Louis.

Louis died suddenly at Nagyszombat (Trnava) on Sept. 10, 1382, leaving his daughters Maria (1371–95) and Jadwiga (1374–99) under his widow's guardianship (an elder daughter, Catherine, had died in 1378). Though he had intended that Jadwiga should have the Hungarian succession and Maria (with Sigismund) the Polish, this arrangement was eventually reversed.

LOUIS II (1506–1526), the last Jagiello king of Hungary and Bohemia, was born on July 1, 1506, the only son of Ulászló (Vladislav) II of Hungary and Bohemia and his French consort Anne de Candale. Prematurely born, he was a sickly child who needed all the resources of medical science to keep him alive, but his intelligence was good and he early learned several languages. In his infancy he was crowned king of Hungary (June 4, 1508) and of Bohemia (May 11, 1509) in order that the succession should be assured to him on his father's death, which took place in March 1516; and he was declared of age to rule on Dec. 11, 1521. Married on Jan. 13, 1522, to Maria of Austria, sister of the Holy Roman emperor Charles V, he embarked with her on a life of riotous pleasure which soon disqualified him for affairs. An object of ridicule at his own court, he was kept by the dominant magnates in such penury that he had often to pawn his jewels to raise money for food and clothing, while his kingdom was rent by faction. After precautions against Turkish invasion had been neglected for four years, Hungarian territory was attacked in the summer of 1526. With an inadequate force, Louis advanced against the Turks and was utterly defeated at Mohács on the Danube, on Aug. 29, 1526. He is said to have been drowned in flight from the battlefield. The German king Ferdinand I, husband of Louis II's sister Anna, then claimed the succession to Hungary and Bohemia.

LOUIS, the name of one king consort and of three titular kings of Naples.

LOUIS OF TARANTO (1320–1362) was born in Naples, the second son of Philip of Anjou, prince of Taranto, who was a younger brother of King Robert. After the murder, in 1345, of Andrew of Hungary, first husband of Queen Joan I (*q.v.*), Louis, who was probably implicated in the crime, himself married Joan in 1347; and when King Louis I of Hungary invaded Naples to avenge Andrew, Louis of Taranto fled with Joan to Pope Clement VI at Avignon. Restored in Aug. 1348, Louis withstood another Hungarian attack (1350–52) and then obtained papal consent to his being formally associated with the throne: he and Joan were crowned by a legate on May 27, 1352. On the first anniversary of this event he founded the Knightly Order of the Holy Spirit. His expedition to Sicily (1356–57) had recovered much of the island from the Aragonese when he was recalled to the mainland to suppress a baronial revolt. He died in Naples on May 24 (or 25–26), 1362.

LOUIS I (1339–1384), the first king of the Valois house of Anjou, was born at Vincennes on July 23, 1339, the second son of the future John II of France, from whom he received the count-

ship of Anjou in apanage before being created duc d'Anjou in 1360. Also in 1360 he was married to Mary of Brittany, daughter of Charles of Blois. Meanwhile he had commanded the French right wing at the battle of Poitiers (1356). Sent to England as a hostage under the treaty of Brétigny (*q.v.*), he escaped back to France; and when Anglo-French hostilities were resumed in 1369 he served his brother King Charles V well. When the papal schism of 1378 broke out, Queen Joan I of Naples, who supported the antipope Clement VII, asked Charles V, who also supported Clement, for help and at the same time named Louis as her heir; but Charles V's death (1380) and the needs of the ensuing regency in France prevented Louis from going promptly to Italy. In June 1382, however, having asserted his control over Provence, he advanced into Italy, gathering considerable forces; but Joan was already murdered by the rival claimant to Naples, Charles of Durazzo (*see CHARLES III*), before Louis reached the kingdom. Avoiding an encounter in Campania, Louis moved into Puglia, whither Charles of Durazzo advanced against him. Before the armies could meet, Louis died at Bisceglie on Sept. 21, 1384.

LOUIS II (1377–1417) was born at Toulouse on Oct. 7, 1377, the son of Louis I, whose titles and claims he inherited in 1384. Three years after Charles III's successor Ladislas (*q.v.*) had been expelled from Naples, Louis took possession of that kingdom (1390); but Ladislas defeated him at Taranto and took the city of Naples in 1399, whereupon Louis withdrew to Provence. He was married in 1400 to Yolande, daughter of John I of Aragon. In 1409, the Council of Pisa's pope, Alexander V, called on Louis for help in driving Ladislas out of the papal states; and after entering Rome with Alexander's successor John XXIII in April 1411 Louis moved southward and defeated Ladislas at Roccasecca on May 19. He failed however to exploit his victory and was driven back to Rome in July, whence he withdrew again to Provence in August. When Ladislas died (1414), Louis appealed to the German king Sigismund for recognition, but in vain. He died at Angers on April 29, 1417.

LOUIS III (1403–1434) was born in Anjou on Sept. 25, 1403, the son of Louis II. When Pope Martin V, in accord with a faction in Naples, recognized him as successor designate to the childless Joan II (*q.v.*), Louis in 1420 mustered support in Italy and sailed to blockade Naples, where Joan had adopted Alfonso of Aragon instead of him. War between Angevin and Aragonese ensued; and in 1423 Joan disinherited Alfonso and adopted Louis instead; but to keep him away from the capital she sent him to govern the duchy of Calabria. Disinherited by Joan in Alfonso's favour in April 1433 but readopted in the following June, Louis died at Cosenza on Nov. 15, 1434, during a campaign against Alfonso's partisan Gian Antonio Orsini, prince of Taranto. His titles passed to his brother René (*q.v.*).

See E. G. Léonard, Les Angevins de Naples (1954). (E. Po.)

LOUIS, king of Portugal: *see* LUIS I.

LOUIS OF NASSAU (1538–1574), one of the leaders in the revolt of the Netherlands against Spanish rule, was the most remarkable of the brothers of William the Silent (*q.v.*), prince of Orange. He was born at Dillenburg on Jan. 10, 1538. Very capable, a good diplomat and a wholehearted Protestant (Lutheran by birth, Calvinist in his later years), he was the right man to take care of his elder brother's relations with German princes and French Huguenots, with the lesser nobility or with the Protestant groups in the Low Countries, or again with the Gueux (*q.v.*) abroad. Living at Brussels from 1556, he became in 1566 one of the leaders of the malcontent gentlemen. Like so many others he went into exile in the following year, but in 1568 he came back at the head of an army invading the northern Netherlands. Victorious over a Spanish force at Heiligerlee, east of Groningen (May 23), an action in which his brother Adolphus was killed, he was himself decisively beaten by the duke de Alba at Jemmappe on the Ems (July 21). He then accompanied William of Orange in an equally abortive campaign in the south and thence to France. There he remained till 1572, fighting in the ranks of the Huguenots, establishing excellent relations with Gaspard de Coligny and through him with the king, Charles IX. A series of attacks on the Netherlands by the Orangists, in alliance with France, was

planned for 1572. The action of the Gueux precipitated events. Louis, with a small army, captured Mons in Hainaut (May 23), where he was besieged from June 3 till Sept. 19. Attempts at relief having failed and the massacre of St. Bartholomew's day (Aug. 24) having shattered all hopes of France's entering the war, he capitulated. Even so, by tying down the main Spanish army during the summer, he had given the rebels in Holland the opportunity to consolidate their positions. In order to lighten Spanish pressure on Holland, Louis in 1574, with a force raised in Germany, tried to cross the Meuse, but Sancho d'Avila, heading him off, crushed his troops on the Mookerheide, south of Nijmegen, on April 14. Both Louis and his younger brother Henry were killed.

LOUIS, JOE (JOSEPH LOUIS BARROW) (1914–), U.S. boxer, held the heavyweight championship of the world longer (1937–49) than any other champion in the division. Born May 13, 1914, at Lexington, Ala., he began his boxing career in Detroit, Mich. He won the lightweight championship in a national tournament in 1934 and was a Golden Gloves title holder; 43 of his amateur bouts were won by knockouts. In his prime Louis stood 6 ft. 1½ in. and weighed about 200 lb. He had his first professional fight in Chicago in 1934, winning by a first round knockout. In his first year as a professional he won 10 of his 12 fights by knockouts; a year later he fought five times in 25 days in one stretch.

Louis knocked out James Braddock in eight rounds to win the world title in Chicago, June 22, 1937, and become the second Negro heavyweight champion. He knocked out six world champions—Primo Carnera, Jack Sharkey, Braddock, Max Baer, Max Schmeling and Joe Walcott. He defended his title 25 times, or more times than the preceding eight champions together. He grossed an estimated \$4,225,000 and participated in three of boxing's \$1,000,000 gates. Louis retired in May 1949. The vacant title was won by Ezzard Charles over Jersey Joe Walcott, whom Louis had previously defeated. Louis challenged Charles and lost a 15-round decision in the title match. Louis served in the U.S. Army during World War II fighting exhibition matches to entertain the troops. He was elected to the boxing Hall of Fame in 1954. See also BOXING. For portrait see article NEGRO, AMERICAN.

(J. D. McC.)

LOUISA ULRICA (1720–1782), queen consort of Sweden from 1751 to 1771, was born in Berlin on July 24, 1720, the fifth surviving daughter of Frederick William I of Prussia and Sophia Dorothea of Hanover. She was educated with her brothers and sisters by French governesses and tutors. Her father's favourite, she was made coadjutor of Quedlinburg in 1743. Her marriage to the Swedish crown prince, Adolphus Frederick, which took place in 1744, was arranged by the empress Elizabeth of Russia; her brother Frederick the Great would have preferred the prince to marry Louisa's youngest sister Amalia. Louisa's eldest son, the future Gustavus III of Sweden, was born in 1746.

In 1750 Louisa Ulrica quarreled with her former friend Count Carl Gustaf Tessin, the most powerful representative of the nobles' interests. On her husband's accession to the throne in 1751 she became the leader of the "court party," seeking to abolish the existing constitution and to strengthen the monarchy against the nobles. Frederick the Great advised her to be more cautious and refused to lend her money to buy support for her plans. After the failure of a *coup d'état* in 1756, she was unable to prevent Sweden's entering the war against Prussia in 1757 (see SEVEN YEARS' WAR); but the disastrous course of the war strengthened her position, and she was instrumental in promoting negotiations for peace in 1762. On her husband's death, in Feb. 1771, she went to Berlin, where she stayed till 1772. Frederick tried to help her in her difficulties with her son Gustavus, now king of Sweden; but Gustavus showed himself increasingly antagonistic to her till her death, at Svartsjö castle near Stockholm, on July 16, 1782.

Louisa Ulrica encouraged the arts and sciences and did much to promote French cultural influence. She was a notable patron

of Linnaeus; she invited Voltaire to settle in Sweden; and in 1753 she founded the Royal Academy of Literature, History and Antiquities (from which, however, the brilliant Tessin was excluded).

Her memoirs and letters were edited by F. Arnheim and published in 1885 and 1909–10, respectively.

See O. Jägerskiöld, *Lovisa Ulrika* (1945).

LOUISBURG (LOUISBOURG), a national historic park in Cape Breton county, Nova Scotia, 26 mi. S.E. of Sydney. After 1713 the French constructed the continent's strongest and most costly fortress at that site. It was captured by New England volunteers in 1745, returned to the French by the treaty of Aix-la-Chapelle in 1748, and recaptured by Gen. Jeffrey Amherst and Adm. Edward Boscawen a decade later. The settlers, numbering about 4,000, were dispersed, and the fortifications were completely demolished. A major restoration of the fortress was begun in 1962.

The modern town of Louisburg (pop. [1961] 1,417) is situated across the harbour. It is a winter shipping port and a centre of fish processing and packing. (C. W. Rd.)

LOUISE OF SAVOY (1476–1531), mother of Francis I of France and twice regent for him, was born at Pont d'Ain on Sept. 11, 1476, the daughter of Philippe, comte de Bresse (later duke of Savoy as Philip II), and Marguerite de Bourbon, sister of three successive ducs de Bourbon. In 1488 Louise was married to Charles de Valois-Orléans, comte d'Angoulême, but he died in 1496, leaving her with two children: Margaret (q.v.), the future queen of Navarre; and the son who was to become king of France as Francis I (q.v.). The accession of her husband's first cousin to the French crown as Louis XII (1498) made Francis heir presumptive to it, and Louise then brought her children to the French court and received Amboise as her residence.

When Louis XII died, on Jan. 1, 1515, Francis became king. Devoted to her son, Louise thenceforward took a major part in the government. Created duchesse d'Angoulême, she was appointed regent when Francis undertook his expedition to Italy (1515–16).

Louise's niece Suzanne de Bourbon died in 1521, leaving all her heritage to her husband, Charles, the constable duc de Bourbon (q.v.). Louise, however, claimed part of this heritage, and this claim did much to push the constable into his treason (1523). Regent again in 1525–26 during the king's second Italian expedition and his captivity in Spain, Louise negotiated to detach Henry VIII of England from alliance with the Holy Roman emperor Charles V. On the other hand her insistence on receiving her personal income from the superintendent of finances, Jacques de Semblançay, when money was needed for the army in Italy, is said to have caused the deficiency for which Semblançay was charged with peculation and executed (1527). It was Louise who, with Margaret of Austria, negotiated the peace of Cambrai or "Ladies' peace" between Francis and Charles (1529). Louise died at Grez-en-Gâtinais, near Fontainebleau, on Sept. 22, 1531. An extensively edited version of her *Journal* is printed in the *Nouvelle Collection des Mémoires*, vol. v (1836).

LOUISIADE ARCHIPELAGO, a group of islands and coral reefs to the southeast of the easternmost promontory of the island of New Guinea, administered by Australia as part of the territory of Papua. Although the islands, which number almost 100, extend over 10,000 sq.mi. of sea, the largest, Sudest (Tagula), measures only about 40 by 7 mi. The principal interest of the islands lies in their structure; rugged and mountainous, they are nevertheless surrounded by the largest coral-fringed lagoons in the southwest Pacific. Misima Island, however, formerly a small gold-mining area, has no lagoon. The group contains no European-owned plantations, but there is a small production of coconuts from native growers. The population numbers about 4,000. Discovered by Luis Vaez de Torres in 1606, the islands were named by L. A. de Bougainville after Louis XV in 1768.

(D. W. F.)

LOUISIANA, one of the west south-central states of the United States at the mouth of the Mississippi river, on the north coast of the Gulf of Mexico. Shaped like a boot, it is bounded on the north by Arkansas; on the east by the Mississippi river and the state of Mississippi; on the south by the Gulf of Mexico; on the west by Texas. The state has an area of 48,523 sq.mi., of which 3,417 are inland water (including 1,060 sq.mi. of landlocked bays called lakes). It borders the Gulf of Mexico for 366 mi. It ranks 31st in size among the states and is popularly known as the "Pelican state"; sometimes as the "Bayou state" and the "Creole state." It was admitted to the union April 30, 1812, and was the 18th state to enter. The 64 political subdivisions called parishes correspond to counties in the other states (see *Governments*, below). Baton Rouge is the capital. The state flag consists of a field of dark blue bearing a white pelican feeding and protecting her brood and a white ribbon below with the state motto, "Union, Justice and Confidence." The unofficial state bird is the eastern brown pelican; the official state flower is the magnolia blossom and the official state tree is the bald cypress.

PHYSICAL GEOGRAPHY

Physical Features.—Louisiana lies roughly between 28° and 33° N. and between 89° and 94° W. Geologically it is a new creation and is classified as a coastal plain province. Its soils were formed as submarine deposits. The average elevation of the state is approximately 100 ft.; the highest point is in Bienville parish, 535 ft. above sea level. The physiographic features may be placed in five classifications: uplands, bluffs, alluvial plains, prairies and coastal marshes. These were successive stages in the geologic process of forming the state. The uplands, or pine hills, are divided into three areas: (1) north of Lake Pontchartrain and east of the Mississippi river; (2) west of Red river; and (3) the north Louisiana uplands lying between the Red and Ouachita rivers. The bluffs run through the second tier of parishes west of the Mississippi above the mouth of the Red river. The alluvial lands are in the flood plains of the rivers, especially the Mississippi, Ouachita and Red. The prairies become increasingly common south of the Red river and constitute the entire southwestern part of the state. The prairies are generally treeless except for marginal timber along the sluggish meandering streams. They are generally 20 to 30 ft. above sea level and shade off into the coastal marshes. The coastal marshes are generally 20 to 30 mi. wide but may reach a width of 60 mi. The alluvial lands and the coast swamps comprise about 20,000 sq.mi. or better than 40% of the area of the state.

Louisiana has within its borders about 7,500 mi. of navigable waters, including harbours, bays and sounds. The principal rivers are the Mississippi, which flows nearly 600 mi. through and along the border of the state, the Red, the Ouachita, the Tensas, the Atchafalaya, the Calcasieu, the Vermilion, the Sabine and the Pearl. Louisiana is the only state that is divided by the Mississippi river. There are a number of bayous which are of great economic importance for navigation, drainage and scenic beauty. The largest of these are Bartholomew, Dorcheat, Macon, Boeuf, Plaquemine, Lafourche and Teche. The alluvial portion of the state, especially below the mouth of the Red river, is an intricate network of these bayous: before their closure by a levee system they served partially, in time of flood, to carry off the escaping surplus of river waters.

The alluvial region of the state is mainly protected against overflow by a system of levees, or earthen walls, that hold the waters within the stream channels. The state and federal government co-operated in the construction and maintenance of this system, although the national government did not give aid, except for a grant of swamplands in 1850, until 1879, when it began acting through a board of engineers known as the Mississippi River commission. The levee system and flood-control projects represent an expenditure of upward of \$500,000,000. Some of the levees are 50 ft. high with a base 100-ft. wide. There are more than 1,700 mi. of levees in the state along the Mississippi, Red, Ouachita and Atchafalaya rivers and other streams.

Some of the lakes, such as Lakes Pontchartrain, Maurepas,

Borgne and Sabine, are merely landlocked salt-water bays, the waters of which rise and fall with the tides. Other lakes are cut-off meanders of the Mississippi and Red rivers, known as oxbow lakes. Others are the result of clogging or blocking the outlets of a river, which impeded the flow and forced the water into swamps and low places. Examples are found along Red river.

Climate.—The climate is semitropical and exceptionally equable over large areas. The mean temperature for southern Louisiana is 68.2° F. (20° C.), and is affected by prevailing southerly winds and the network of bays, bayous and lakes. The differences of mean annual temperature are almost wholly caused by differences of latitude or elevation. The mean annual temperature for northern Louisiana is 65.2°. The lowest temperature recorded at New Orleans is 7° (about -13° C.) and the highest 102° (about 33° C.). The lowest and highest temperatures recorded at Shreveport, about 300 mi. N.W., are -5° and 110° respectively. New Orleans has an average of 60 in. of rainfall annually and the mild climate makes possible a growing season averaging 330 days per year. Shreveport has an average precipitation of 44.8 in. and the growing season averages about 209 days. The first severe frost seldom comes before Nov. 15 in the Shreveport area, and the last one is usually before March 15.

Soil.—Louisiana lies entirely in the coastal plain and the soil was once marine sediments. The soil of the uplands, or rolling hills, is now relatively low in nutrient level. This soil is relatively coarse and adapted to forest growth, especially pine trees. It requires fertilizers to produce good crops of cotton and corn. The alluvial and bluff soils are fertile and produce abundant crops. The prairie soil is clay and clay-loam and is well adapted to rice culture and to pasturing. The coastal marshes are used primarily for the production of fur-bearing animals and for sanctuaries for birds and migratory fowl, for which the state is well known.

Vegetation.—The state has approximately 150 species of trees. The several kinds of pine are the most valuable. The cypress of the swamps; the tupelo gum, slash pine, sweet and black gums of the lowlands; the shortleaf and longleaf pines, the hickory, 15 varieties of oak and birch on the uplands; plus the trees of minor importance make up the state's forests. Although most of the virgin stands of pine, cypress and tupelo gum have been cut, farmers with woodland plots and owners of cutover tracts have engaged in reforestation and more than half the land area is in forests. The Kisatchie National forest, in the central part of the state, is one of the largest of the reforestation projects. Approximately 12,500,000 pine seedlings were planted there during one 12-month period.

Louisiana has a great variety of wild flowers and shrubs. Azaleas, camellias, crape myrtles, redbuds and magnolias bloom in profusion, both wild and cultured.

Animal Life.—The variety and number of wild animals and fowl give the state the reputation of being a hunter's paradise. The white-tailed deer is found throughout the state and the black bear and the wildcat inhabit the swamp forests. The smaller mammals include opossum, raccoon, otter, skunk, gray fox, squirrels, cottontail and marsh rabbit, weasel, mink, rats, muskrat and moles. Louisiana leads all other states in the number of fur-bearing animals and formerly led in the value of furs produced, but in the second half of the 20th century the value of Louisiana furs declined considerably.

It has been found that 108 species of amphibians and reptiles are native to the state. There are 42 amphibians with 18 belonging to the salamander group; the remaining 24 are frogs and toads. The native reptiles are represented by 66 species, of which the alligator is the largest. There are ten different kind of lizards and 35 species of snakes. Fortunately, only five species of snakes are poisonous. These are the coral snake, the copperhead, the water moccasin, the ground rattler and the canebrake rattler. Twenty species of turtle are native to the state.

The coastal marshes are the greatest winter resort in North America for wild ducks and geese. The commonest varieties of ducks are the mallard, teal, shoveler, gadwall and pintail. It is thought that most of the blue geese of North America winter in the marsh area of the state. The coastal area is visited by many

sea birds, such as the laughing gull, royal tern, brown pelican, plover, black skimmer and sandpiper. The area is the habitat, also, of the marsh wren, seaside sparrow, Louisiana heron, Wilson's snipe, woodcock and red-winged blackbird.

Among the swamp-loving birds are the American egret, wood duck, great blue heron, ivory-billed woodpecker, bald eagle, cardinal and warbler. In addition to the ducks and geese, the principal game birds are the turkey, bobwhite, upland plover and dove. The wild turkey is found on or near the bluffs adjacent to the stream bottoms. In the upland areas can be found the thrasher, wood thrush, blue jay, mockingbird, catbird, southern whippoorwill, flicker, redheaded woodpecker, Baltimore oriole, bluebird, tanager and bunting.

State and National Parks.—The most important of the state parks are Audubon, Abita Springs, Bogue Falaya, Chemin-A-Haut, Chicot, Fontainebleau, Ft. Macomb, Ft. Pike, Lake Bistineau and Longfellow-Evangeline. The state has a number of game preserves for wildlife and migratory fowl in particular. The most important of these are the Louisiana State Wild Life refuge, State Public Game and Fish preserve, the Terzia Wild Life refuge, Sabine Migratory Waterfowl refuge, Lacassine Migratory Waterfowl refuge, Russell Sage Wild Life Refuge and Game preserve, Rockefeller Wild Life Refuge and Delta Migratory Waterfowl refuge. There are a number of fish hatcheries, pine seedling nurseries and the state forest near Alexandria. Chalmette National Historical park was the scene of part of the battle of New Orleans (see also *Historic Sites*, below). The Caney Creek and Cornie Creek parks are recreational and forestry development areas under the supervision of the federal government.

Historic Sites.—The first permanent European settlement in the present state of Louisiana was Fort St. Jean Baptiste (Natchitoches) built in 1714 by Louis Juchereau de St. Denis. Fort Los Adais, near Robeline, was built in 1721 by the Spanish. Other historic sites include Fort Jesup in Sabine parish, Forts Jackson and St. Philip in Plaquemines parish and Fort Humbug in Caddo. Chalmette National Historical park is in the Chalmette battlefield and the Pleasant Hill and the Mansfield battlefields have areas set aside as parks. The *Vieux Carré* in New Orleans contains many historic buildings such as the Cabildo and St. Louis cathedral; the U.S. military barracks in Baton Rouge were constructed in 1822. The most noted Indian sites are the Indian mounds at Jonesville, Marksville and Poverty Point on Bayou Macon near Delhi.

HISTORY

Indians inhabited the northern portion of the state approximately 2,500 years before Columbus' voyages to the new world, as revealed by the mounds at Poverty Point on Bayou Macon. At the time and for a few hundred years preceding the arrival of Europeans in the region, various tribes of the Caddoan confederacy occupied the northern half of the state. At the time white men came, remnants of various other tribes were found in the eastern and southern portions of the state.

The Spanish knew of the land on the northern shores of the Gulf of Mexico by 1510 and it is possible that one or more Spanish explorers saw the mouth of the Mississippi river before the followers of Hernando de Soto. Alonso Álvarez de Piñeda was in the region in 1519, as was Cabeza de Vaca and the survivors of the Narváez expedition of 1528, but there is no positive proof that they saw the Mississippi.

De Soto crossed the river below Memphis and it is probable that he entered the present state of Louisiana before he died. Survivors of his expedition descended the river to its mouth in 1543. Having found no gold or silver mines, the Spanish made no effort to plant colonies on or near the Mississippi river. In 1682 René Robert Cavelier, sieur de La Salle, went down the river from the French possessions in Canada and claimed all the land drained by the river and its tributaries for Louis XIV of France and named it Louisiana. La Salle obtained permission to establish a colony in 1684, failed to find the mouth of the river and landed on the coast of Texas. His efforts to locate the river were futile and he was slain by some of his men in 1687. Eleven years later

Pierre le Moyne, Sieur d'Iberville (1661–1706), took up the task of colonizing Louisiana and in 1699 built a fort near the present city of Biloxi, Miss. The next year he erected a fort on the Mississippi 18 leagues (about 40 mi.) above its mouth. This was the first settlement in what is now the state of Louisiana. Antoine Crozat (1655–1738) was granted possession of Louisiana in 1712 for a period of 15 years. The proprietary contract was terminated in 1717, but the first permanent settlement in the present state was made in 1714 at Natchitoches, on the Red river. Louisiana was too much of a drain on the royal treasury and in 1717 the territory was granted to a company organized by John Law (*q.v.*), who did much for the colony before surrendering Louisiana to the crown in 1731. Jean Baptiste le Moyne, Sieur de Bienville (1680–1768), a younger brother of D'Iberville, was the guiding spirit of the colony from 1699 until 1743. It was he who founded New Orleans in 1718. The French began the cultivation of rice, tobacco and sugar cane, but it was not until 1795 that sugar cane became a commercial crop.

The Spanish Period.—The secret treaty of Fontainebleau, Nov. 3, 1762, transferred Louisiana from France to Spain. The next year England received that portion of Louisiana lying east of the Mississippi and Iberville rivers and Lakes Maurepas and Pontchartrain. Many colonists were unhappy over the transfer to Spain and the leaders resisted Spanish possession. When the director of Louisiana, D'Abbadie, issued the proclamation of transfer in 1764 the colonial leaders petitioned to remain French. The first governor Spain sent over, Antonio de Ulloa (1716–95), never took formal possession and was ordered to leave in 1768. Alexander O'Reilly, an Irish officer in the Spanish army, was sent to the colony with a force of about 3,000 men. His affability caused suspicion to subside until he had ascertained the identity of the leaders who opposed Spanish rule. He then invited them to a reception, arrested them, executed five and sent the others to prison in Havana, Cuba. The succeeding Spanish rulers were liberal and tolerant. While Spanish was the official language, the colony remained French in manners and customs. The Spanish governors, while neglecting to enforce the regulations of commerce, instituted a number of reforms that proved beneficial to the people and in the course of time the populace came to appreciate the benefits of Spanish rule. The Spanish officials received the French exiles from Acadia and granted them lands along Bayou Teche. These Acadians made a distinct contribution to the cultural and economic life of the territory.

Some of the Spanish governors endeavoured to induce the people living in the region east of the Mississippi river and west of the Appalachian mountains to secede and join Spanish Louisiana. The river, as the highway of transportation, was used as a bargaining weapon in these efforts.

In 1800 Napoleon coerced Spain into ceding Louisiana to France. The United States frowned upon the transfer because free navigation of the Mississippi was imperative to the people who lived in the valley. Napoleon sold Louisiana to the United States, which took formal possession Dec. 20, 1803. William C. Claiborne was appointed by President Jefferson to receive Louisiana from the French official, Pierre Clement de Laussat. A short time thereafter Claiborne was made governor of the territory. (See LOUISIANA PURCHASE.)

Territory and Statehood.—Congress provided a government for the territory on March 25, 1804. The act divided the Louisiana Purchase into two territories. The portion south of 33° N. became the Territory of Orleans, with an estimated population of 30,000. The act forbade importing slaves from foreign countries, made English the official language and provided a government less democratic than if the inhabitants had been Anglo-Saxon. The people desired immediate statehood. After the census of 1810, the people in the territory of Orleans held a convention to frame a state constitution and Louisiana became a state April 30, 1812.

Spain refused to surrender the area east of the Mississippi river, and this area south of 31° N., east to the Pearl river and north of Lake Pontchartrain, revolted in Sept. 1810 and established the Republic of West Florida. Three months later, however, it came under the jurisdiction of Governor Claiborne. A few days after

Louisiana was admitted to the union, congress added West Florida to the state. This area is often referred to as the "Florida parishes."

Claiborne was elected the first governor of the state in 1812 and in that year the first steamboat descended the Mississippi river to New Orleans. Gen. Andrew Jackson's forces defeated a British army under Gen. Edward Pakenham at Chalmette, near New Orleans, Jan. 8, 1815, two weeks after the treaty of Ghent was signed ending the War of 1812.

Up to 1860 the state increased in population and prospered from agriculture and commerce. During this period the sugarcane and cotton plantations were flourishing. The river steamboats dominated transportation and New Orleans was the gateway for the trade of the Mississippi valley. The capital was moved from New Orleans to Donaldsonville, 1828-31, and to Baton Rouge, 1849-64, and again after 1882. At other times New Orleans was the capital and a number of state offices have always remained there.

Civil War and Reconstruction.—Louisiana formally seceded from the union Jan. 26, 1861 and six weeks later joined the Confederate States of America. During 1861, many of the young men in military units were sent to Tennessee, Kentucky and Virginia to defend the borders of the Confederacy. New Orleans was taken in April 1862 by a naval force under David G. Farragut and an army commanded by Gen. B. F. Butler. Butler's military administration became so notorious that he was replaced in Dec. 1862 by Gen. N. P. Banks. The capture of Vicksburg and Port Hudson by Union forces in July 1863 opened the Mississippi to navigation. The attempt to capture Shreveport on the Red river resulted in the defeat of General Banks by the Confederates under Gen. Richard Taylor at Sabine Crossroads, near Mansfield, April 8, 1864.

The reconstruction of the state began in Dec. 1862, when President Lincoln ordered the Union military government to hold elections for congress. Those chosen were seated in Feb. 1863. Civil government superseded military rule in March 1864 and during the year a convention assembled to rewrite the state constitution. The reconstructed government represented half of the area, two thirds of the population of the state and was backed by the army.

The Confederate government under Gov. Thomas O. Moore (1860-64) and Gov. Henry W. Allen (1864-65) was at Shreveport. Thus Louisiana had two governments during most of the war. The people of Louisiana accepted military defeat and by 1866 the former Confederates had succeeded in gaining possession of most of the local government and most of the state offices, although not of the governorship. The radicals were not pleased with the situation and wanted to convene a convention to rewrite the constitution. Unable to call a convention through the medium of state government, they endeavoured to reconvene the constitutional convention of 1864. The effort to disperse the illegal convention in 1866 resulted in the death of almost 50 persons, mostly Negroes. The incident was used by politicians to overthrow presidential Reconstruction and institute congressional Reconstruction in 1867. The state constitution of 1868 gave suffrage to the Negroes and disfranchised a large number of white citizens. Probably no other southern state suffered as much as Louisiana under the corrupt carpetbag government of 1868-76, during the administrations of Henry Clay Warmoth (1868-72), P. B. S. Pinchback (one month in 1872) and William Pitt Kellogg (1872-76). The Democrats claimed the election of John McEnery in 1872, but the federal government supported the Republican, Kellogg. A number of clashes occurred between the factions, the most noted of which was Sept. 14, 1874, in New Orleans, when the White league briefly wrested control of the city from the Republican police. In 1876 the Democrats claimed that Gen. Francis T. Nicholls was elected but the Republicans claimed that S. B. Packard had won. Their claims were intertwined with the choice of presidential electors for that year. The Republicans manipulated the state returning board and sent two sets of election returns to congress and the Democrats sent their returns. The electoral commission accepted the Republican electors, just as it did those in dispute from South Carolina, Florida and Oregon. Both Nicholls and Packard took

the oath as governor in Jan. 1877 and set up rival government which continued until President Hayes ordered the withdrawal of federal troops from the capital on April 20, 1877, and the white Democratic party was left in control.

After 1877 the state began to reconstruct its economy. Efforts were made to attract settlers; a new constitution was written in 1879; the channel of the Mississippi river was deepened at its mouth by the construction of jetties to increase maritime shipping, and railroads were built to facilitate overland transportation; levees were constructed to prevent floods; and efforts were made to curb the ravages of malaria and yellow fever. By 1900 the state had made some headway and was on the threshold of spectacular economic developments through the exploitation of the state's abundant natural resources of oil, gas, sulfur, salt and timber.

20th Century.—In the spring of 1927 the most devastating flood in the history of the state inundated 1,300,000 ac., drove 300,000 people from their homes and destroyed millions of dollars' worth of property. The catastrophe proved the inadequacy of the existing levees and demonstrated that flood control of the Mississippi river was a responsibility of the federal government. In 1928 congress responded by appropriating \$325,000,000 for that purpose.

The government of Louisiana was dominated by landed gentry until 1928 when the election of Huey P. Long as governor challenged the old regime and a tumultuous political era began with the rural and working classes pitted against the urban leaders. Long won a vast following and built a formidable political machine. In the U.S. senate (1930-35) he attracted national attention with his Share the Wealth program before he was assassinated in 1935. He had modernized the highway system; expanded the Louisiana State university and hospitals; provided free textbooks for school children; constructed a new state capitol and governor's mansion; and built a sea wall, an airport, a bridge over the Mississippi river and a spillway at New Orleans. His political machine lost in the governor's election of 1940, after Oscar K. Allen and Richard W. Leche had been elected governor in 1932 and 1936, respectively, and Alvin O. King (Jan. to May 1932), James A. Noe (Jan. to May 1936) and Earl K. Long (June 1939 to May 1940) had served to fill unexpired terms.

The so-called reform administrations of governors Sam H. Jones and James H. Davis appeared to achieve some improvement. Earn K. Long, brother and political heir of Huey, was elected in 1944 and expenditures for education, hospitals and welfare were greatly increased. Robert F. Kennon defeated Long's candidate, Judge Carlos G. Spaht, in 1952 but Long was elected again in 1956. Governor Long, in three mental institutions within a period of a month in 1959, sought to circumvent the constitutional provision that a governor could not succeed himself but eventually fled as a candidate for lieutenant governor on the ticket of James A. Noe. The ticket was defeated in the primary. Long was subsequently nominated for congressman from the 8th district but died suddenly on Sept. 5, 1960, before the election. Governmental expenditures in Louisiana increased precipitously after 1930, in greater proportion than did those of neighbouring states.

In national politics the traditionally Democratic state was carried by the Dixiecrats in a three-cornered fight among the States' Rights Democrats, Democrats and Republicans in 1948. In 1952 both Democratic and Republican presidential candidates campaigned in the state for the first time in many decades. The Democratic candidate, Adlai Stevenson, carried the state. In 1956, with less than 40% of the electorate voting, a Republican presidential candidate, Dwight Eisenhower, carried the state for the first time since Reconstruction (1877). In 1960 Louisiana returned to the Democratic fold, voting for John F. Kennedy, but in 1964 again went Republican, for Barry Goldwater.

GOVERNMENT

The Roman law was the basis of legal procedure in Louisiana under both French and Spanish regimes. The French and Spanish had divisions of territory for religious administration. These religious divisions, known as parishes, were conveniently used for civil administration, hence the names of saints in parish names.

clature. The territorial act of 1804 used "county" to designate governmental subdivisions. In 1807 the nomenclature for these units was changed back to "parish" and that term still is used for 64 local units of government.

Louisiana has had ten constitutions since becoming a state in 1812; the present constitution, adopted June 18, 1921, has been amended more than 300 times.

The legislative branch of government consists of two houses—the senate with 39 senators elected from 33 districts and the house of representatives of 101 members. The regular session of the legislature, convening in May of the even-numbered years, is limited to 60 days. The session convening in May of the odd-numbered years is limited to 30 days and can only consider financial legislation unless three-fourths of the members consent.

The judicial authority is vested in a supreme court, 7 courts of appeal and 25 judicial district courts, with each police jury (parish governing body) authorized to establish justice of peace courts, and with municipalities having the power to create juvenile and municipal courts. The supreme court is composed of a chief justice and six associate justices, elected from six supreme court districts (district one elects two). Their term is for 14 years with the term of one expiring every two years. The state, exclusive of the parish of Orleans, is divided into two circuits, with three courts of appeal in each and an additional court for Orleans parish. Each court of appeal has three judges elected for a term of 12 years. There are 25 judicial districts, with one judge elected for a period of six years to serve each judicial district court, except three districts that have two or three judges each.

The executive branch of government consists of the governor, lieutenant governor, auditor, treasurer, secretary of state, registrar of the land office, commissioner of agriculture and labour, commissioner of conservation, attorney general and superintendent of public instruction.

Suffrage is granted to every citizen of the state who has attained the age of 21 and who has resided in the state two years, in the parish one year and in the precinct three months preceding the election; who is legally enrolled as a registered voter; and who is of good character.

Real-estate taxes have become a minor source of state revenue. The chief source of revenue is the general sales tax; other sources of revenue are severance taxes; mineral leases and royalties; gasoline, income, tobacco, beverage and gas-gathering taxes; vehicle licences and fees; corporation franchise taxes; excise licence taxes; and insurance licences and fees. The chief expenditures are for education, public welfare, highways, hospitals and institutions, homestead exemptions, debt service and general government.

Law.—Louisiana civil law is based to a great extent on the French and Spanish laws and especially the Code Napoléon. The other states base their laws on the common law of England. Louisiana was first of the southern states to abolish the poll tax and the first state to provide free textbooks and free lunches for elementary-school students. A law was enacted in 1936 to exempt from taxation homesteads up to a valuation of \$2,000.

POPULATION

The descendants of the French are found in the area bounded roughly by a line from the southwest corner of the state to the juncture of the Red and Mississippi rivers and from that point along the Mississippi to the Gulf of Mexico. Few Spanish came during the 35 years the colony belonged to Spain. St. Bernard has the largest Spanish influence. The Italians, the most numerous of the modern immigrant groups, are principally in the cities. Hungarians are found in the strawberry belt, Slovenians in the fishing and citrus-fruit districts and Germans in and near New Orleans.

The population of Louisiana has increased steadily since 1810 when it was 76,556; in 1850 it was 517,762; in 1900, 1,381,625; in 1950, 2,683,516; and in 1960 was 3,257,022. The population per square mile in 1960 was 67.1 as compared with 55.3 in 1950 and with 49.6 for the U.S. in 1960. The 1960 census gave 63.3% of the population living under urban conditions as compared to 54.8% in 1950 and 41.5% in 1940 which indicates a marked acceleration of the urbanization trend first noted about 1900. *Populations are reported as constituted at date of each census. †Ward 4 of Jefferson parish, which includes Westwego.
Note: A dash indicates place did not exist during reported census or data not available.

five standard metropolitan statistical areas (Baton Rouge, Lake Charles, Monroe, New Orleans and Shreveport) in 1960 contained about 50% of the total population of the state. The number of Negroes is not increasing as rapidly as the white race and the Negroes are moving to urban areas. Negroes constituted 31.9% of the population in 1960 and 33% in 1950. The number of people over 65 and the number under 15 years of age constitute a larger relative percentage of the total population; that is, the age group, 15 to 65, is not increasing in numbers as rapidly as the younger and older age groups. The number of births per 1,000 population in 1960 was 27.7% and in 1950 it was 29.7%.

EDUCATION

Elementary and Secondary.—Education was the function and responsibility of the church during the French period. During the Spanish period, although the church exerted the most powerful influence, the government did make a pretense of establishing a free public-school system in 1771 when four professors were sent from Spain and Governor Unzaga was ordered to pay their salaries out of the general fund until permanent taxes for the purpose could be provided. Only one such school was opened (in 1772) and it never enrolled more than 30 students.

During the early years of the American period the people were too busy developing the new country to devote much energy and attention to schools. This was especially true of the Anglo-Saxon Protestants who settled the uplands of northern Louisiana before 1860. The Anglo-Saxons who settled in the southern portion of the state were, generally speaking, sons of slave owners of Vir-

ginia and the Carolinas, who believed that education was the responsibility of parents and who hired tutors or sent their children to private schools. This class, together with the older French settlers, who considered education to be a function of the church, usually controlled the government of the state and never made a sincere effort, such as New England made, to establish a free tax-supported school system. Hence education received only token support and few free schools were opened outside New Orleans. John McDonogh, a wealthy New Orleans merchant and financier who died in 1850, left half his fortune for the promotion of education in New Orleans. Before the American Civil War most of the free schools there were supported from this fund.

A few tax-supported schools were opened in the 1880s but the economic conditions of the state did not make possible the development of a free-school system until 1910. Tremendous progress has been made since that time in the number of children in school; the number and training of the teachers; the financial expenditures; and the construction of school plants. Although earlier statutes authorized parish police jurors to provide free textbooks for the children of parents unable to purchase them, Governor Long in 1928 sponsored a free-textbook law for all the children of the state. Later governors instituted free-lunch programs and paper, pencils and other materials were provided from tax funds. The automobile and the development of good roads made possible the consolidation of schools so that better-trained teachers and modern library, laboratory and classroom facilities became generally available. The one-room school has disappeared. The first compulsory school attendance laws were enacted in 1916. By 1950 attendance in elementary schools was compulsory for children between the ages of 7 and 15, inclusive, and approximately 94% of the children between 6 and 18 years of age attended school; public high schools enrolled a larger proportion of the elementary school graduates than ever before and a greater proportion of high-school graduates entered college. Education had become the most important enterprise in the state and took the largest portion of the tax dollar. The annual state budget for education increased precipitously in the decade after 1950, reaching more than \$175,000,000 or about \$55 per child for the more than 900,000 children of school age in the state; expenditures per pupil in average daily attendance reached \$330.

Administration.—The head of the public-school system is the state superintendent of public education who is elected for a term of four years by popular vote. An 11-member state board of education, elected by popular vote for overlapping terms, has general jurisdiction over all tax-supported elementary, high, special and trade schools and institutions of higher learning except Louisiana State university, its branches in New Orleans and Chambers and its medical school, also in New Orleans, which are under the supervision of a special board of 15 members appointed by the governor for a term of 14 years, the term of two members expiring every two years. In addition, each of the parishes and three of the cities have school boards, with a superintendent.

In the second half of the 20th century there were about 24,000 teachers and principals in the tax-supported elementary and secondary schools. Of these approximately 16,000 were white, staffing about 850 schools with approximately 400,000 students; about 8,000 were Negroes staffing about 550 Negro schools with approximately 126,000 students. The salary schedule is the same for all teachers of equal training and experience. After World War II the state made impressive efforts to provide equal facilities for white and Negro children.

Private and parochial schools for white children numbered about 240 with about 3,000 teachers and approximately 95,000 students. There were about 100 such schools for about 23,000 Negro students, taught by about 650 teachers.

Segregation.—Following the U.S. supreme court decision (1954) declaring racial segregation in the public schools to be unconstitutional, the Louisiana legislature in 1956 exempted from the compulsory attendance laws any school ordered by the federal courts to desegregate, and the state constitution was amended, authorizing the legislature to maintain segregation. The 1960 legislature enacted additional measures but court decisions that

same year indicated that all such acts would be held unconstitutional, and while they might delay integration they could not prevent it. The courts ordered integration in New Orleans (Orleans parish) and in East Baton Rouge, St. Helena, St. Bernard and Tangipahoa parishes by 1964. Roman Catholic Archbishop Joseph F. Rummel ordered all Catholic parochial schools integrated as soon as the public schools in those parishes were integrated. Many Catholics objected and at least three of the segregation leaders were excommunicated.

Higher Education.—The growth and development of higher education was dependent upon the elementary- and secondary-school system and therefore lagged behind it. The State Seminary of Learning and Military institute opened near Alexandria in 1860 with William T. Sherman as president and eventually grew into the Louisiana State University and Agricultural and Mechanical college. It is one of the state's two land-grant schools, the other being Southern University and Agricultural and Mechanical college (for Negroes). The buildings burned in 1869 and the institution was moved to Baton Rouge where it was housed in the State School for the Deaf until 1885. The Agricultural and Mechanical college was moved from Donaldsonville to Baton Rouge in 1877 to be operated in conjunction with the university because of limited finances; the temporary union has proved to be permanent. Two brothers, David French Boyd and Thomas Duckett Boyd, directed the institution for most of the period, 1884-1927, the latter serving as president from 1896 to 1927. Gov. John McMilliken Parker advocated a greater Agricultural and Mechanical college in 1920 and purchased a plantation for the site. The university rejoined the college on its 4,700 ac. campus in 1925. The medical school was established in New Orleans (1934) as a branch of the university and in 1958 Louisiana State university in New Orleans was opened as another branch. A junior-college branch was established at Chambers in 1959. The university was ordered by the U.S. courts to admit Negroes to its graduate and professional schools (1951) and then to its undergraduate branch at New Orleans (1958). At various dates the courts ordered Negro admission to Southeastern Louisiana college, the University of Southwestern Louisiana (formerly Southwestern Louisiana institute), McNeese State college and the state trade schools.

The Louisiana State Normal school, opened at Natchitoches in 1884, was made a four-year college in 1917 and the name was changed. For 30 years it enjoyed a monopoly of training teachers for the public schools. After the other state colleges began training teachers, the Normal college expanded its services and the name was changed to Northwestern State College of Louisiana. It is divided into five schools: arts and sciences, applied arts and sciences, education, nursing and the graduate school.

Louisiana Polytechnic institute, Ruston, was established in 1884 as the Louisiana Industrial Institute and college. It was made a four-year college in 1917 and its name was changed in 1926. The organization consists of six schools: arts and sciences, agriculture and forestry, business administration and economics, education, engineering and home economics. The teacher-training program began in 1917 and a graduate program for the master's degree in 1958.

The University of Southwestern Louisiana, Lafayette, was opened in 1901 as the Southwestern Louisiana Industrial institute. The name was changed to Southwestern Louisiana institute in 1920 and to the present name in 1960. It is organized into schools of agriculture, commerce, engineering, home economics, liberal arts and nursing. With over 5,000 students, it has the second largest enrollment of any state-supported college. It began a graduate program for the master's degree in 1956.

Southeastern Louisiana college, Hammond, operated as the Tangipahoa junior college in the early 1920s, then as the Florida Parishes junior college and was taken over by the state and made a four-year college in the late 1930s. It is organized into three schools: liberal arts, applied sciences and education.

Northeast Louisiana State college, Monroe, had its origin in the Ouachita Parish Junior college in the early 1930s. It was taken over by the Louisiana State university in 1934 and operated as a branch junior college. In 1950 the legislature made it a full

year college and placed it under the jurisdiction of the state board of education with the name changed to the Northeast Louisiana State college. It has schools of arts and sciences, pure and applied sciences, education, fine arts and pharmacy.

McNeese State college, Lake Charles, began as a junior-college branch of Louisiana State university in 1939. The legislature, in 1950, changed its name, made it a four-year college and placed it under the jurisdiction of the state board of education.

The Francis T. Nicholls State college was authorized in 1946 as the Francis T. Nicholls junior college of Louisiana State university. In 1956 the legislature designated it as a four-year college and placed it under the state board of education. The instruction is divided into three divisions designated as colleges: applied sciences, arts and sciences and education.

The state operates two institutions of higher education for its Negro citizens: Southern University and Agricultural and Mechanical college and Grambling college. Southern university was founded in 1880 in New Orleans and was moved to Scotlandville (near Baton Rouge) in 1914. Progress was slow during the early years because the state was not in a financial condition to support higher education until around 1920 and relatively few students sought a college education before that date. Increasing prosperity enabled the state to provide more funds for buildings, equipment and salaries, the increase in funds being precipitous in the period 1940-60. The institution has divisions of arts and science, agriculture, home economics and industrial and technical education (formerly mechanic arts), health and physical education, business, music, a graduate school and a law school. The enrollment is more than 5,000. A branch of Southern university opened in New Orleans in 1961.

Grambling college had its origin in 1901 when Booker T. Washington, president of Tuskegee institute, sent one of his recent graduates, Charles Adams, to establish a private school for Negroes at Grambling. Lincoln parish assumed support of the school in 1918 and the state took it over in 1928 and operated it as a normal school to train teachers and leaders in agriculture. It was made a four-year college of liberal arts and a teachers college in 1940 and has had a phenomenal growth since the end of World War II. The institution is operated by departments under the immediate supervision of the dean of the college.

Private institutions of higher learning include four Roman Catholic schools in New Orleans: Loyola university (for men, founded 1912); Notre Dame seminary (for men, 1923); St. Mary's Dominican college (for women, 1920); and Xavier University of Louisiana (1925). Also in New Orleans are Dillard university (Congregational Christian and Methodist, 1930); Tulane university (nonsectarian, 1834); and Newcomb college (The H. Sophie Newcomb Memorial College of Tulane university) (for women, 1896). Centenary College of Louisiana (Methodist, 1825) is at Shreveport and Louisiana college (Louisiana Baptist convention, 1905) is at Pineville. Tulane was integrated in 1961.

HEALTH AND WELFARE

Beginning about 1906 Louisiana made rapid progress in eradicating and controlling disease. Laws were passed and enforced to destroy the breeding places of mosquitoes, thereby reducing malaria and yellow fever; rats were exterminated to reduce the spread of such diseases as bubonic plague; the hookworm disease was attacked; houses were screened; public drinking cups were outlawed to help control the spread of tuberculosis; and other measures in the interest of better health were enacted.

Hospitals.—The first charity hospital was built in New Orleans in 1736 with the bequest of a sailor, Jean Louis. This was the forerunner of the Charity hospital there constructed by the state in 1930 at a cost of \$13,000,000. Additions costing approximately \$7,500,000 have been made. Charity hospitals are found in all the larger urban centres, as, for example, the Confederate Memorial hospital in Shreveport, the E. A. Conway hospital in Monroe and the Huey P. Long Charity hospital in Pineville. The East Louisiana hospital for the mentally ill at Jackson is the oldest (1847) and largest of its kind in the state. The mentally ill also are provided for in the Central Louisiana State hospital at Pineville and

the Southeast Louisiana hospital at Mandeville and there are sections and wards for the mentally ill in most of the state hospitals. The federal government has two magnificent hospitals for veterans of the armed forces, at Pineville and Shreveport.

The Spanish Governor Miro (1785-92) was responsible for establishing a hospital for lepers (Hansen's disease) in New Orleans. This was the beginning of a state leprosarium, established at Carville in 1894 and taken over by the federal government in 1921. Officially designated the U.S. Marine Hospital No. 22, it is the only leprosarium in the continental United States.

In addition to the tax-supported hospitals there are a number of private- and church-supported institutions. The Roman Catholic Church has had unusual success in operating hospitals and the Protestant denominations, the Baptist in particular, have entered this field of service.

Welfare.—A state-wide poor law was passed as early as 1880 requiring every parish in the state to provide for its poor and infirm through local taxation. Various laws after 1900 provided pensions for dependent mothers, compensation to incapacitated workers and child welfare. The first state-wide system of relief grew out of the need resulting from the depression of the early 1930s. In 1932 an unemployment relief committee was set up to supervise the distribution of relief funds provided by the federal Reconstruction Finance corporation. Within a period of three years a local welfare agency was in existence in every parish. A state department of public welfare was created by act of the legislature June 26, 1936.

The welfare services have expanded to enormous proportions. The budget of the welfare department in the second half of the 20th century was almost equal to the budget for education. The largest items of expenditure were for old-age assistance, for dependent children, for the permanently and totally disabled and for general assistance. By the 1960s, 70% of the population age 65 and over were receiving some form of relief.

THE ECONOMY

Louisiana has a mild climate and more and more people have been attracted to the state to live, as is borne out by the number of adults who move into the state and by the growing population. The state also has attracted a number of industries since passing in 1946 a law granting new industry tax exemption for a period of ten years.

The trend toward better homes was pronounced after 1935. New construction was of better quality and more of the rural homes were painted. By the second half of the 20th century practically all urban homes had electricity, running water and indoor plumbing and an increasing number of rural homes had these conveniences. Most of the homes, even in the rural areas, were heated by natural or manufactured gas. The wood formerly burned for heating and cooking was sold for pulpwood and other uses.

Agriculture.—Agriculture was the chief occupation and the main source of income for the people until World War II. Agriculture is still important although it has been superseded by manufacturing as the leading industry in the state. The number of farm workers declined from about 200,000 at the end of World War II to about 150,000 in the second half of the 20th century. The number of farms also decreased from about 150,000 to about 110,000 while the average value of farms rose from about \$3,500 to almost \$10,000 and the size of the average farm increased from about 65 ac. to more than 100 ac. (but about 46% of the farms were less than 30 ac. in size). At the same time the number of acres that were harvested decreased from almost 3,500,000 ac. to about 2,500,000 ac. This trend was evident in the reduction of acres in row crops and the increasing acreage in pasture for livestock and for growing forests. In the second half of the 20th century the total annual value of Louisiana agricultural products reached \$400,000,000, of which livestock products accounted for about \$140,000,000, plus \$30,000,000 in government payments.

The major crops, ranked according to value, were cotton lint and cottonseed, rice, sugar cane, corn, hay and sweet potatoes. In the ten years after World War II the average acreage planted in cot-

ton was about 825,000 ac. with an average production of about 600,000 bales (500 lb. per bale) worth more than \$100,000,000. The acreage planted in cotton, however, was decreasing, in some years dropping to fewer than 400,000 ac. planted and a production of less than 300,000 bales. Louisiana has led all the states in the production of rice. During the post-World War II years an average of about 600,000 ac. were planted with the annual production exceeding 1,000,000,000 lb. worth approximately \$60,000,000. Louisiana produces most of the sugar from sugar cane in continental United States, with Florida producing a small amount. The average acreage planted in sugar cane in the post-World War II period was about 250,000 ac. which produced more than 5,000,000 tons of sugar worth more than \$33,000,000. The corn planted during the period averaged almost 800,000 ac. and production was about 14,000,000 bu. valued approximately at \$20,000,000; the hay crop averaged about 350,000 ac. with 434,000 tons valued at \$10,000,000. Louisiana ranks first in the production of sweet potatoes. The crop averaged about 90,000 ac. and produced 500,000,000 lb. worth more than \$15,000,000. Rice and sugar cane are the only field crops with restricted areas of production. The sugar-cane region is confined, almost exclusively, to the Mississippi delta and Bayou Teche regions, while the chief area of rice production is the prairie region of the southwestern part of the state.

The rice farms were almost the only farms irrigated until the second half of the 20th century. The water was procured from the streams flowing through the rice-growing area and from deep wells. During the 1950s lightweight aluminum pipe became available and enabled vegetable and even cotton and corn crops to be irrigated during dry years. The water was procured largely from streams and ponds.

The growing of vegetables has not been exploited to any great extent to utilize the soil and climate. It has developed most in the vicinity of New Orleans. With the growth of other large urban centres, the growing of vegetables in these vicinities has increased. Louisiana ranks first among the states in the production of strawberries. The strawberry area is in the Florida parishes, east of Baton Rouge, but the plant can be grown in most of the state. Other commercial vegetable crops are Irish potatoes, snap beans, green peppers, shallots, cabbages, tomatoes, watermelons, onions and cucumbers. The crop of oranges, grown south of New Orleans, is important. Peach growing in north Louisiana has proved profitable. Other important farm products are pecans, peanuts, figs, tung oil nuts and soybeans.

Livestock is playing an increasing role on Louisiana farms notwithstanding the rapid decline in the number of horses, mules, hogs and sheep. Mechanization is rapidly replacing the horse and the mule. In the ten years after World War II they numbered an average of 210,000. By 1960 the number decreased to less than 100,000. Hogs averaged 574,000 head in the post-World War II period. By 1960 the number was below 400,000. Sheep declined from an average of almost 120,000 to fewer than 100,000 head, but the value increased from less than \$1,000,000 to more than \$1,100,000. In livestock, cattle led in value followed by commercial broilers, hogs, horses and mules, chickens and sheep.

Industry.—The industries of Louisiana are those associated, for the most part, with petroleum, lumbering, sugar, rice and cottonseed. Manufacturing could be classified, also, as those processing: (1) food and kindred products; (2) petroleum; (3) forest products; and (4) chemical and allied products. Industries processing agricultural raw material are seasonal. Examples are cottonseed oil mills, sugar refineries, sirup mills and canning plants. Manufacturing increased at a rapid rate after World War II, especially in the rubber, petroleum-chemical, aluminum making and papermaking industries. In the second half of the 20th century there were more than 3,000 manufacturing plants operating in the state with almost 150,000 production workers and an annual payroll of more than \$600,000,000. The value added by manufacturing amounted to approximately \$1,500,000,000 annually.

While the amount of board feet of lumber produced declined in the second half of the 20th century the amount of wood pulp increased from 590,000 tons annually before World War II to approximately 1,500,000 tons. Louisiana has approximately 16,

000,000 ac. in forests with 41,436,000,000 board feet of standing timber; the annual growth is approximately equal to the amount harvested. The pine and cypress forests make up most of the softwoods while the leading hardwoods are oak, red gum and tupelo gum. It has been demonstrated that pine trees grow faster in Louisiana than anywhere else in the world. The soil, rainfall and long growing season of the state are ideally adapted to the growth and manufacture of timber and timber products.

Mining.—The principal minerals of the state are petroleum (including gas), salt, sand and gravel, and sulfur. The value of minerals produced in the second half of the 20th century was more than \$2,000,000,000 a year. Louisiana usually ranks second or third of all the states in the value of minerals and produces more than 10% of the total value of all minerals in the nation. Nineteenth of the total labour force in the mineral industry was producing petroleum, natural gas and natural-gas liquids. Petroleum production increased from 23,000,000 bbl. (42 gal. per barrel) in 1930 to more than 400,000,000 bbl. in the 1960s. Natural-gas production increased from about 700,000,000 cu.ft. after World War II to about 3,000,000,000 cu.ft. in the second half of the 20th century and natural-gas liquids rose from 17,000,000 bbl. to 26,000,000 bbl. The total proved reserves in the second half of the 20th century were petroleum, more than 5,000,000,000 bbl., natural gas, 72,000,000,000 cu.ft., and natural-gas liquids, 1,000,000,000 bbl.

Only Texas and California produce more petroleum and natural gas than Louisiana and they are the only states that have more proved reserves. Louisiana ranks fourth among the states in the production of salt, and sulfur production for industrial use began in the state. Louisiana has been surpassed by Texas, but the opening in 1933 of the Grande Écaille mine, about 50 mi. S. of New Orleans, and in the 1960s of a big offshore mine in the Gulf of Mexico greatly increased sulfur production in Louisiana. The mining of sulfur along the gulf coast by the Frasch process is accomplished by pumping superheated steam into the sulfur rock melting and forcing it to the surface through pipes. The sulfur is often hundreds of feet beneath the surface of the earth and sometimes there is a layer of quicksand above the sulfur. The annual average production of sulfur, about 1,000,000 tons before 1950, after 1950 reached more than 2,000,000 tons valued at more than \$50,000,000. Sulfur and petroleum form the base for the growing petroleum-chemical industry in the state. The average annual production of salt, about 2,000,000 tons before 1950, after 1950 rose to approximately 4,500,000 tons. There are a number of known untouched salt domes in the state. The best-known mines are at Avery Island, Jefferson Island and Winnfield. The average annual production of cement, about 4,500,000 bbl. before 1950, after 1950 increased to about 7,500,000 bbl. The cement is procured from clays and oyster shells. The mining of miscellaneous clays, which previously averaged about 300,000 tons, more than doubled in the second half of the 20th century.

The value of all mineral production in the state exceeds \$2,000,000,000 annually, with petroleum the most valuable, accounting for more than \$1,000,000,000, natural gas for \$250,000,000 and natural-gas liquids for \$80,000,000. The number of producing oil wells, fewer than 10,000 in 1948, increased to more than 25,000 in the 1960s. The average daily production per well, however, decreased from 54.7 bbl. to 41.3 bbl.

Fisheries and Wildlife.—Louisiana is widely known for the quality and great variety of its fresh- and salt-water fish. The value of the annual catch is approximately \$33,000,000 and 31,000 persons are employed in the industry. The leading salt-water fish are shrimp, oysters, crabs, pompanos, redfish, bluefish, Spanish mackerel, flounder, grouper (yellow bass) and drumfish. The fresh-water streams abound in perch, basses, barfish, catfish, gar, pergou (a fresh-water drumfish), sacalait (also known as crappie), warmouth and killfish), bullfrogs and buffalo fish. The annual catch of buffalo fish approaches 12,000,000 lb. and that of catfish approximates 5,000,000 lb. Louisiana supplies approximately 34,000,000 lb. of shrimp annually worth about \$10,000,000. The 10,000,000 lb. of oysters taken annually from 477,000 ac. of oyster beds have a value approximating \$3,000,000. The oyster shells are

important as a source of lime for making cement, and for liming or "sweetening" acid soils. The state is the leading producer, also, of diamondback terrapins, crabs and bullfrogs.

The original French settlers came to Louisiana for the fur trade and the state leads all others in the number but not in the value of furs produced. The annual yield approaches 2,500,000 pelts worth approximately \$3,000,000. The muskrat leads in number and value, followed in value by mink, nutria, otter, raccoon and opossum. The wildlife and fisheries commission spends approximately \$500,000 annually supervising the wildlife and fisheries.

Trade.—New Orleans ranks second among the ports of the U.S. in value of exports and imports; approximately 10% of the national foreign trade passes through the port. More than 100 steamship lines offer regular sailings from the port. Approximately 65 firms in the towing barge business operate through New Orleans with 15,000 mi. of commercial waterways converging on the city bringing over 150,000,000 tons of freight annually. The port annually handles more than 10,000,000 tons of foreign goods valued at more than \$1,500,000,000. The most valuable imports are bananas, coffee and molasses.

The ports of Lake Charles, Baton Rouge and Morgan City have, in the second half of the 20th century, become increasingly important in the foreign trade of the state. In the second half of the 20th century about 25,000 retail firms annually sold more than \$2,225,000,000 worth of merchandise and about 3,500 wholesale firms approximately \$150,000,000 worth. Business activity by 1960 was 70% above the average of ten years earlier. Over 600,000 persons were employed in the state, with average weekly earnings of about \$83; the per capita income for the state was a little over \$1,500 compared to the national average of about \$2,000.

Transportation and Communication.—In the second half of the 20th century there were ten major railroads, with 6,000 mi. of track; nine commercial airlines and more than 100 airports; 5,000 mi. of navigable streams; 1,100 mi. of intercoastal canals; and almost 50,000 mi. of vehicular roads, of which more than 15,000 mi. were under state control, and of these approximately 14,000 mi. were paved with asphalt or concrete. There are over 5,000 bridges in the highway system. Two bridges at New Orleans, one at Baton Rouge and one at Natchez span the Mississippi river. Other important bridges span the Red, Ouachita and Atchafalaya rivers at important points.

There are about 20 daily newspapers with paid circulation of more than 700,000. Practically every town of a few thousand population has a radio station and the larger cities have one or more television stations.

Culture and Recreation.—Most of the larger urban centres have little-theatre groups for the performance of amateurs on the stage. The New Orleans Opera association and similar organizations at most of the colleges and universities stage plays, produce operas and give concerts of creditable quality. A number of musical groups such as the New Orleans Symphony orchestra, the Shreveport symphony and others give excellent group and solo performances. The educational extension department of Louisiana State university has attempted to preserve the folklore, folk dances and arts and crafts of the Acadians. The Louisiana State library has promoted the establishment of parish libraries with bookmobiles to transport the books directly to rural families. The university, through its agricultural extension department, has endeavoured to organize "communities" of farm families throughout the state for recreational purposes.

There are a number of fairs to teach and demonstrate improved machinery, utensils, livestock and poultry. The largest of these is the state fair at Shreveport. There are a number of festivals with colourful pageants and ceremonies, such as the Shrimp festival at Morgan City, the Rice festival at Crowley, the Forest festival at Winnfield, the Yambilee at Opelousas and the Peach festival at Ruston. The Mid-Winter Sports carnival at New Orleans, which sponsors the Sugar Bowl football game on New Year's day, and the Christmas festival at Natchitoches are well known. The oldest and most famous of the festivals is Mardi Gras in New Orleans. See also references under "Louisiana" in the Index.

LOUISIANA PURCHASE. In 1803 the United States purchased from Napoleonic France the then vaguely delineated western half of the Mississippi river basin. This region was then known as "Louisiana," and its acquisition by the United States is referred to as the Louisiana Purchase. The term is commonly applied to the territory involved as well as to the act of purchase itself.

The Louisiana territory had been the object of old world interests for many years before 1803. Explorations and scattered settlements in the 17th and 18th centuries had given France control over the river itself and title to most of the Mississippi valley.

The first serious disruption of French control over Louisiana came during the Seven Years' War (q.v.). In 1762 France ceded Louisiana west of the Mississippi river to Spain and in 1763 transferred virtually all of its remaining possessions in North America to Great Britain. This arrangement, however, proved temporary. French power rebounded under the subsequent military leadership of Napoleon Bonaparte and on Oct. 1, 1800, Napoleon induced a reluctant King Charles IV of Spain to agree for a consideration to cede Louisiana back to France. King Charles gave at least his verbal assent on the condition that France would never alienate the territory to a third power. And with this treaty of retrocession, known as the treaty of San Ildefonso, would go not only the growing and commercially significant port of New Orleans but the strategic mouth of the Mississippi river.

Reports of the supposed retrocession soon were received by official Washington—and with deep misgivings. During the preceding 12 years, Americans had streamed westward into the valleys of the Cumberland, Tennessee and Ohio rivers. The very existence of these new settlers depended on their right to use the Mississippi river freely and to make transshipment of their exports at New Orleans. By terms of the treaty of San Lorenzo, Spain in 1795 had granted to the United States the

right to ship goods originating in American ports through the mouth of the Mississippi without paying duty and also the right of deposit, or temporary storage, of American goods at New Orleans for transshipment. But in 1802 Spain in effect revoked the right of deposit, and so it was in an atmosphere of growing tension in the west that Pres. Thomas Jefferson was confronted with the prospect of a new, wily and more powerful keeper of the strategic window to the Gulf of Mexico.

The news of the retrocession remained unconfirmed for months, and understandably so. Quite apart from persistent and conflicting rumours that would naturally surround secret negotiations of this magnitude, it was subsequently revealed that King Charles had put off signing the retrocession order until Oct. 15, 1802. But even though it was extremely difficult for American agents in Paris to ascertain the exact facts pertaining to the status of Louisiana, the information that did reach President Jefferson was disquieting. The president, sensitive to America's growing interests in the west, would look upon any foreign power that controlled the Mississippi river mouth as a "natural and habitual enemy" of the United States, and he was quick to view the possible possession of this region by Napoleon with added misgivings. "The day that France takes possession of New Orleans," the normally pro-French Jefferson wrote Robert R. Livingston, the U.S. minister at Paris, "... we must marry ourselves to the British fleet and nation."

Jefferson meanwhile instructed Livingston to take two steps: (1) to approach Napoleon's minister, Charles Maurice de Talleyrand, with the object of preventing the retrocession in the event this act had not yet been completed; (2) to try to purchase at least New Orleans if the property had actually been transferred from Spain to France. Direct negotiations with Talleyrand, however, appeared to be all but impossible. For months Livingston had to be content with tantalizing glimmerings of a possible deal between France and the United States. But even these faded as news of the Spanish governor's revocation of the right of deposit reached the U.S. minister. With this intelligence he had good reasons for thinking the worst: that Napoleon Bonaparte may have been responsible for this unfortunate act; that his next move might be to close the Mississippi river entirely to the Americans. Livingston had but one trump to play and he played it with a flourish. He made it known that a *rapprochement* with Great Britain might, after all, best serve the interests of his country, and at that particular moment an Anglo-American *rapprochement* was about the least of Napoleon's desires.

No one can write with certainty of the mental deliberations of the first consul. But there are good reasons for believing that French failure in Santo Domingo, the imminence of renewed war with Great Britain and financial stringencies may all have prompted Napoleon in 1803 to offer for sale to the United States the entire Louisiana territory. At this juncture, James Monroe arrived in Paris as Jefferson's minister plenipotentiary; and even though the two American ministers possessed neither instructions nor authority to purchase the whole of Louisiana, the negotiations that followed, with Barbé-Marbois acting for Napoleon, moved swiftly to a conclusion. A treaty was signed on May 2, but was antedated to April 30. By its terms the Louisiana territory, in the form France had received it from Spain, was sold to the United States. For this vast domain the United States agreed to pay \$11,250,000 outright and assumed claims of its citizens against France in the amount of \$3,750,000. Interest payments incidental to the final settlement made the total price \$27,267,622.

Minister Livingston, with the help of Monroe, had bargained well, and he knew it. As he was about to affix his signature to the documents, Livingston is reported to have said: "We have lived long, but this is the noblest work of our whole lives. . . . From this day the United States take their place among the powers of the first rank. . . ." Napoleon, too, reflected upon what he had done and remarked to Barbé-Marbois: "This accession of territory (by the Americans) affirms forever the power of the United States, and I have just given England a maritime rival that sooner or later will lay low her pride."

But what had the Americans really bought? According to

art. i of the terms of sale, "The colony or province" of Louisiana consisted of the "same extent" that it had under Spain at the time of the retrocession (1800) and that it had when France possessed it (prior to 1762); art. ii specifically took in all adjacent islands (and this would, of course, include the vital Isle of Orleans); "all public lots and squares, vacant lands and all public buildings, fortifications, barracks, and other edifices which are not private property"; and archives.

The wording of art. i was vague; it did not precisely describe the boundaries. It gave no assurances that West Florida was to be considered a part of Louisiana; neither did it delineate the southwest boundary. The American negotiators were fully aware of this. When Livingston later questioned Talleyrand on the matter, the reply was: "I do not know . . . I can give you no direction; you have made a noble bargain for yourselves, and I suppose you will make the most of it."

But before the United States could establish fixed boundaries to Louisiana there arose a basic question concerning the constitutionality of the purchase. Did the constitution of the United States provide for an act of this kind? The president, in principle a strict constructionist, thought that an amendment to the constitution might be required to legalize the transaction; but, after due consideration and considerable oratory, the senate approved the treaty by a 24 to 7 vote.

The setting of fixed boundaries awaited negotiations with Spain and Great Britain. The exasperating dispute with Spain over the ownership of West Florida and Texas was finally settled by the purchase of the Floridas from Spain in 1819 and the establishment of a fixed southwest boundary line. This line followed the Sabine river from the Gulf of Mexico to the parallel of 32° N.; ran thence due north to the Red river, following this stream to the meridian 100° W.; thence north to the Arkansas river and along this stream to its source; thence north or south as the case might be (the source of the Arkansas was not then known) to the parallel of 42° N. and west along this line to the Pacific ocean. The northern boundary was amicably established by an Anglo-American convention in 1818. It established the 49° parallel N. between the Lake of the Woods and the Rocky mountains as the American-Canadian border. The Rocky (then referred to as "Stony") mountains were accepted as the western limit of the Louisiana territory, and the Mississippi river was considered for all practical purposes the eastern boundary of the great purchase. The new territory, which comprised 828,000 sq. mi. and doubled the size of the United States, was acquired at a cost of less than three cents per acre. Much of the territory turned out to contain rich mineral resources, productive soil, valuable grazing land, forests and wildlife resources of inestimable value. Out of this empire were carved in their entirety the states of Louisiana, Missouri, Arkansas, Iowa, North Dakota, South Dakota, Nebraska, Oklahoma; in addition, the area included most of the land in Kansas, Colorado, Wyoming, Montana and Minnesota.

The acquisition of the Louisiana territory greatly strengthened the United States, materially and strategically. It provided a powerful new impetus to westward expansion of the American people, and in a constitutional sense it established in practice the doctrine of implied powers of the federal constitution. The Louisiana Purchase was what often has been said of it, the greatest bargain in American history. (See also LOUISIANA: History.)

BIBLIOGRAPHY.—The official literature is in the *American State Papers, Foreign Relations*, vol. II, IV; *Public Lands*, vol. II, 2d session (1903). Among the more useful secondary accounts are John K. Hosmer, *The History of the Louisiana Purchase* (1902); Henry Hitchcock, *The Louisiana Purchase and the Exploration, 1803-1804* (1903); Curtis M. Geer, *The Louisiana Purchase and the Westward Movement* (1904); Thomas M. Smith, *A History of the Western Boundary of the Louisiana Purchase, 1819-1841* (1914); E. S. Brown, *The Constitutional History of the Louisiana Purchase* (1920). Extremely interesting, but heavily weighted on Napoleon's venture in Santo Domingo, is Henry Adams, *History of the United States*, vol. I-II (1889).

LOUIS PHILIPPE (1773-1850), king of the French from 1830 to 1848, was born at the Palais Royal in Paris on Oct. 2, 1773, the eldest son of Louis Philippe Joseph de Bourbon-Orléans

at that time duc de Chartres, later duc d'Orléans, and Adélaïde de Bourbon-Penthièvre (for the allegation that he was a supposititious child see MARIA STELLA). At first styled duc de Valois, he was educated by Madame de Genlis. When his father became duc d'Orléans (1785), Louis Philippe became duc de Chartres, titular colonel of a dragoons regiment of that name, and titular governor of Poitou.

The Jacobin Officer (1790-93).—At the beginning of the French Revolution, following his ambitious father's example, Louis Philippe joined the Jacobin club in 1790 and was considered one of the most progressive members of the nobility, especially when he resigned command of his infantry regiment in 1791. In 1792 he joined the army of the north as colonel of the 14th dragoons. His exemplary conduct in the first engagements soon won him promotion to command of a brigade; and in September he became lieutenant general on Kellermann's staff and was present at the battle of Valmy (Sept. 20, 1792; see FRENCH REVOLUTIONARY WARS). His father, meanwhile, had changed his name to Philippe Égalité and had been elected to the National Convention in Paris. Louis Philippe subsequently served under Dumouriez in Belgium and was present at the victory of Jemappes (Nov. 6, 1792) and at the defeat of Neerwinden (March 18, 1793). Some weeks later, however, though his father in Jan. 1793 had voted for the execution of Louis XVI, Louis Philippe associated himself with Dumouriez in deserting the revolutionary cause and in coming to terms with the Austrians. But he did not put his services at the disposal of the enemies of France; instead, he went to Switzerland, for a short while joining his sister Adélaïde who had earlier gone there from Tournai. His father was then arrested in Paris.

Exile (1793-1814).—For a time the refugee Louis Philippe taught at the college at Reichenau in the canton of Graubünden (Grisons), using the assumed name of Chabaud de la Tour. The execution of Philippe Égalité in Nov. 1793 now made him duc d'Orléans and he became the centre of the Orleanist intrigues. But he refused to countenance any plan to set himself up as king in France, possibly because he was negotiating with the revolutionaries for the release of his two brothers, the duc de Montpensier and the comte de Beaujolais, who had been arrested at the same time as their father. Louis Philippe traveled in Scandinavia for about a year (1795-96); then he sailed to the United States and settled in Philadelphia, where in Feb. 1797 he was joined by his brothers. They spent more than two years in America, until, on hearing of Napoleon Bonaparte's *coup d'état* of 18 Brumaire (Nov. 9, 1799), Louis Philippe decided to return to Europe. But when he and his brothers reached England early in 1800, the power of the first consul was so well established that there was no hope of intervening in France. Instead, the house of Orléans became reconciled with the elder branch of the Bourbon family. Even so, Louis Philippe never took up arms to fight with *émigré* forces for the royalist cause against other Frenchmen, as the princes de Condé had done: perhaps Louis XVIII mistrusted Philippe Égalité's son too much to allow him any close contact with French troops; or perhaps Louis Philippe himself merely preferred to remain with his brothers, who had both developed tuberculosis (Montpensier died in 1807, Beaujolais in 1808).

After a long residence at Twickenham in Middlesex, Louis Philippe in 1809 went to join the Neapolitan royal family at Palermo in Sicily; and on Nov. 25 he married Marie Amélie (*q.v.*), a daughter of King Ferdinand IV of Naples. About this time there was some suggestion that Louis Philippe should join the English forces in the Peninsular War; but nothing came of it, probably because Louis XVIII again feared any activity that might further the Orleanist cause.

The Bourbon Restoration (1814-30).—Louis Philippe returned to France at the first Restoration (1814). Though Louis XVIII refused to grant him the style of royal highness (later allowed to him by Charles X), he received from the king the dignities traditionally held by the head of his family; *e.g.*, that of colonel general of hussars. More important perhaps, he regained possession of the family estates and forests that had not been sold after his own emigration and his father's execution. During the

Hundred Days (1815) he returned to England instead of following the court to Ghent.

Under the second Restoration the duc d'Orléans was a steady and more or less open adherent of the liberal opposition, entertaining its most prominent deputies and journalists at the Palais Royal and giving open patronage to the opposition newspaper *Le Constitutionnel* and tacit support to the more radical and Orleanist organ *Le National* (started in Jan. 1830). He may have had cognizance of various plots against the regime, such as that of Jean Paul Didier at Grenoble in 1816. Meanwhile, he sent his sons *en bourgeois* to be educated at the Collège Henri IV in Paris instead of employing private tutors as was customary among the nobility; he was a member of the Paris Philhellenic committee; and above all, he was occupied in recovering and restoring the estates and property that had belonged to his family before the Revolution. Though the indemnity granted in 1825 to the *émigrés* for estates seized during the Revolution was opposed by his political friends, the duc d'Orléans was one of its principal beneficiaries: it added several million francs to his fortune. Even so, he had to provide for six sons and three daughters (see BOURBON: Table IV) and thus was glad to help the baronne de Feuchères to win recognition at court in return for her services in persuading her lover, the last prince de Condé, to make Louis Philippe's son Henri, duc d'Aumale, his residuary legatee. Later when he had become king and his eldest son Ferdinand Philippe was heir to the royal domain, he could reserve the Orléans inheritance for his other sons, instead of merging it with the crown lands.

The July Revolution.—The publication by Charles X of the ordinances which provoked the July revolution of 1830 gave Louis Philippe his long desired opportunity. During the days of crisis he kept away both from the court at St. Cloud and from the revolutionaries in Paris, waiting first at his château at Neuilly and later at Le Raincy, where he was in less danger of sudden arrest by the king's guard. Late on July 30 he went to Paris. The next morning, wrapped in the tricolour flag beloved alike by Republicans and by Bonapartists, Orléans went to the Hôtel de Ville, where he was embraced by Lafayette, commander of the national guard and the veteran hero of the liberal opposition. Meanwhile the deputies of the existing legislature had elected him lieutenant general of the kingdom (July 31). Charles X confirmed him in this appointment two days later, before abdicating in favour of his ten-year-old grandson, the duc de Bordeaux (the comte de Chambord). On Aug. 7 the provisional government of deputies and peers present in Paris declared the throne vacant; following the terminology of 1791 Louis Philippe was, on Aug. 9, proclaimed "king of the French by the grace of God and the will of the people." A modified version of the charter of 1814 was issued, which the new king was obliged to accept.

The King of the French (1830-48).—The July monarchy, with its citizen king, could never command the support of Legitimists, Republicans or Bonapartists; and its opponents resorted to political intrigue, to insurrection and even to attempted assassination, such as the attack made by Giuseppe Fieschi (*q.v.*). Indeed, it was said that "for shooting kings there is no close season." Nevertheless Louis Philippe showed increasing determination to strengthen his own control over affairs; and when the Party of Resistance, which wanted to maintain the new order and to prevent any more radical development, came into office with Casimir Périer in March 1831, the speech from the throne proclaimed that, "France has desired that the monarchy should become national, it does not desire that it should be powerless." Republican and socialist agitation, culminating in a series of dangerous risings such as that at Lyons in Nov. 1831 and that at Paris in June 1832, enabled the king to represent himself as the defender of middle class interests; and since the middle classes alone were represented in the assembly, Louis Philippe came to regard his position as unassailable. The nature of the opposition that he encountered at home served to conciliate opinion abroad where this "king of the barricades" had at first been regarded as a usurper. The Russian and Austrian courts, however, never really overcame their doubts about him; the Austrians, for instance, refused to give the archduchess Maria

Theresa (a niece of the emperor Francis I) in marriage to his son Ferdinand, now duc d'Orléans and heir to the throne. Louis Philippe had eventually, in 1837, to accept as daughter-in-law the princess Helena of Mecklenburg, who thus became the first Protestant member of the French royal family for more than 300 years. The accidental death of the popular duc d'Orléans in July 1842 not only grieved Louis Philippe very deeply but also seriously weakened the dynasty: the new heir to the throne, the duc's son Louis Philippe Albert, comte de Paris, was an infant for whom a regency had to be prearranged.

It is difficult to assess the motives behind the king's changing attitude toward Great Britain. At first the marriage (Aug. 1832) of his daughter Louise with Queen Victoria's uncle Leopold I, king of the Belgians, established an excellent relationship between Paris and London, almost foreshadowing the Entente Cordiale. This was imperiled in 1840 when Louis Adolphe Thiers, as foreign minister, tried to achieve an exclusively French solution of the dispute between Turkey and Egypt. François Guizot, who succeeded Thiers, managed to repair the breach, and Queen Victoria visited France in 1843 and 1845; but the British were finally alienated by Louis Philippe's policy on the "Spanish marriages." In an attempt to revive the traditional family alliance between the French and Spanish Bourbons he had at first wanted to marry his sons, the duc d'Aumale and the duc de Montpensier, to the Spanish queen Isabella II and to her sister and heiress presumptive, the infanta Luisa, respectively. In view of British objections to this threat of French predominance in Spain he had in 1843 agreed that Isabella should marry neither Aumale nor the British nominee, Prince Leopold of Saxe-Coburg, but some Spanish Bourbon instead, and that Montpensier's marriage to Luisa should not take place until Isabella should have produced an heir or heiress apparent. Consequently the British government was enraged at French duplicity when, on Oct. 10, 1846, Montpensier was married to Luisa simultaneously with Isabella's marriage to Don Francisco de Asís, a cousin supposedly too decrepit to become a father.

By this time French opposition to the regime had become much more embittered. Louis Philippe's constant refusal of any electoral reform meant that many members of the lower middle class from whom he might still have drawn support remained without the vote. Finally, his narrow-minded conservatism and his unwillingness to seek any solution for pressing political and social problems drove many divergent interests into union against him.

The Revolution of 1848.—The July monarchy was but one casualty of the great revolutionary movement that swept through Europe in 1848. But in any case a change had come to seem unavoidable in France. In face of the "banquets campaign," begun in 1847 by those desiring parliamentary reform, Louis Philippe and his minister Guizot remained supine. Faced with insurrection, Louis Philippe abdicated on Feb. 24, 1848, in favour of his grandson the comte de Paris. With Queen Marie Amélie he escaped to Honfleur and thence to England. Under the incognito of comte and comtesse de Neuilly they settled at Claremont in Surrey, placed at their disposal by Queen Victoria. There Louis Philippe died, on Aug. 26, 1850.

Evaluation.—The July monarchy was really an anachronism. To the French people, for whom, whether or not they favoured the institution, monarchy meant the splendours and absolutism of the *ancien régime*, the spectacle of a sovereign who walked unattended in the streets, clad in a sober bourgeois suit and carrying a furled umbrella, and who shook hands with his subjects, soon aroused contempt. Louis Philippe's determination to amass estates and wealth could also be lampooned as a bourgeois quality and few who criticized it knew of his private generosity to individuals and charitable causes. He faced with great courage the frequent attempts made upon his life, showing the same steadfastness that had brought him through many vicissitudes to the throne. In power Louis Philippe strove to implement his desire to rule as well as to reign. But the political difficulties with which he was faced revealed in him the weaknesses of an obstinate man; increasingly his only response to crises was words and theories, and ultimately inaction lost him his crown.

Louis Philippe's own memoirs are contained in the *Journal du duc de Chartres, 1790–91* (1792); *Mon journal: Evénements de 1815*, two volumes (1849); *Discours, allocutions et réponses de sa majesté Louis Philippe, 1830–1846* (1847); and *Correspondance, mémoires et discours inédits de Louis Philippe d'Orléans*, edited by E. Dentu (1863).

LOUIS STYLES refer to the artistic trends during the reigns of Louis XIII, XIV, XV and XVI of France; the styles coincide roughly with the broader classifications of late Renaissance, baroque, rococo, and neoclassical art (*q.v.*), respectively. With Louis XIII (1610–43) the contemporary Italian influence, as exemplified in the Luxembourg palace, was strong. Under Louis XIV (1643–1715) the building of the Versailles palace, establishment of the academies and royal manufactory of tapestries, furniture and ceramics gained cultural hegemony for France. The sober restraints of the baroque grand manner were cast off with Louis XV (1715–74) in favour of the capricious, graceful rococo, which flourished in such smaller Parisian residences as the Hôtel Soubise.

The simple classic ideal, as seen in the Petit Trianon, once again reasserted itself in Louis XVI's reign (1774–93).

See also references under "Louis Styles" in the Index.

See S. F. Kimball, *The Creation of the Rococo* (1943). (Wm. F.)

LOUISVILLE, the largest city of Kentucky, U.S., and seat of Jefferson county, is the metropolitan centre of the state. It is located on the south bank of the Ohio river opposite the Falls of the Ohio, the rock ledge which divides the water levels, about 90 mi. S.W. of Cincinnati. The city spreads across the broad level shoulder of the Ohio flood plain between the river and the rim of knobs. This plain is a fertile area, which was once overflowed and enriched by the Ohio river. In the past the city has recurrent floods which caused heavy damage to property, notably the great flood of Jan.–Feb. 1937. In 1956, a 17-mi. levee was completed along the river front to seal out floodwaters.

Metropolitan Louisville spreads over almost three-quarters of the 375 sq.mi. of Jefferson county. Pop. (1960) city, 390,639; county, 610,947; standard metropolitan statistical area (Jefferson county, Ky., and Clark and Floyd counties, Ind.), 725,139. (For comparative population figures see table in KENTUCKY Population.)

History.—Legend has it that the sieur de La Salle visited the site in 1669, but this is doubtful. French and British traders stopped at the Falls of the Ohio before the middle of the 18th century, but details of their visits are unrecorded. On July 8, 1773, Capt. Thomas Bullitt reached the falls with a commission from William and Mary college in Virginia to survey lands in the area. Though the county surveyor refused to approve this survey, Lord Dunmore, the governor of Virginia, conveyed it in Dec. 1773 to his friend John Connolly. In June 1774 Daniel Boone and Michael Holsteiner came from Virginia to warn the survey party of the outbreak of Lord Dunmore's War against the Indians.

In May 1778, George Rogers Clark (*q.v.*) landed his militia company on Corn Island opposite the mouth of Beargrass creek and began preparation for the conquest of the British-held Old Northwest. Clark built blockhouses for his stores, and cabins for some of the colonists who had come with him. Most of the settlers moved to the mainland the following winter and established themselves in Fort-on-Shore (Ft. Nelson) within the present limits of Louisville. Trustees were appointed to lay out a town and a town government was organized in April 1779. On May 14, 1780, the Virginia legislature, petitioned by the town folk, declared that Connolly had forfeited his title (he had been actively pro-British during the American Revolution) and incorporated the settlement under the name of Louisville, in recognition of the assistance given by Louis XVI of France to the colonists in the Revolutionary War. Between 1780 and 1811 Louisville became an important frontier and flatboat trading place, and

growth was greatly stimulated by the successful introduction of steam navigation. Nicholas Roosevelt docked the "New Orleans," the first steamboat on the western waters, in 1811 and inaugurated the steamboat era which was one of the town's most dramatic. By 1820 Louisville had become a major river port and the development of its facilities was further stimulated by the construction (1825-30) of the canal around the Falls of the Ohio. The steamboat spread the city's commercial influence over a vast area. Louisville merchants were engaged in trade with both the south and the middle west and cotton planters depended upon them for supplies. The town's printers furnished books and periodicals to an ever-widening educational trade area, and its newspapers were read from Alabama to Illinois.

In 1828 the town was chartered as a city and received successive charters in 1851, 1870, 1893 and 1926.

In the American Civil War, Louisville was early occupied by Federal troops who made it a military headquarters and a major supply depot throughout the struggle. Though no fighting took place in the city, its war history constitutes one of its most exciting chapters. Except for the disruption of trade and the normal intercourse with the rest of Kentucky, Louisville escaped the ravages of war. Large numbers of slaves flocked to the town from the plantations seeking passes to enable them to cross the river to Indiana and freedom.

Immediately after the war, Louisville businessmen began a campaign to reclaim the South's trade. The Louisville and Nashville railroad was already directed toward the heart of the south, and this important rail line was extended to Mobile, Ala., and New Orleans, La., and then to Jacksonville, Fla. Both merchant and railway officials helped locate store sites in the south as outlets for goods transported by rail from Louisville distributors.

In March 1890 a tornado caused the loss of more than 100 lives and did extensive property damage. Louisville's economy remained stabilized but was given a boost during World War I with the building of Camp Zachary Taylor just outside the city and the influx of thousands of soldiers. Later the enlargement of nearby Ft. Knox (q.v.) had a similar effect. By mid-20th century newer industries, notably the 1,000-ac. manufacturing plant called Appliance Park, quickened the city's economic pulse.

Industry.—Since 1865 Louisville manufacturers have produced a highly diversified assortment of goods. Traditional manufactures are processed meats, flour, wagons and carriages, whisky, beer, tobacco products, plumbing fixtures, processed foods, wood products, chemicals, textiles, sporting goods, musical instruments, metal goods and clothing. Newer industries include automobiles, tractors, farm implements, rubber goods, electrical machinery and aluminum products. Louisville is still an important printing centre producing large numbers of magazines, comic books, catalogues, commercial brochures and beer and whisky labels. The American Printing House for the Blind, which publishes books in braille, is located there.

Culture and Recreation.—From its beginning Louisville was an important cultural centre. Its newspapers, especially the *Louisville Journal*, edited by George D. Prentice, 1830-68, and the *Louisville Courier-Journal*, edited 1868-1918 by "Marse" Henry Watterson, are distinguished in the history of U.S. journalism. Among the cultural institutions which have given the city character are the Louisville Free Public library, the Speed Memorial Art museum and the Filson club (founded 1884 as a historical library and museum).

The city's system of public education began in 1829. The University of Louisville (founded in 1798 as Jefferson seminary and chartered under its present name in 1846) has, among others, faculties of law, medicine and engineering, and is municipally owned. Among the other educational institutions are the Roman Catholic colleges Bellarmine (1950), Nazareth (1920) and Ursuline (established in 1921 as Sacred Heart junior college and chartered under its present name in 1938); and the Southern Baptist Theological seminary (1859) and the Louisville Presbyterian Theological seminary (1901). The Louisville public school system was one of the first large southern city systems to abandon the practice of racial segregation in compliance with the 1954

supreme court decision, which held segregation to be unconstitutional.

Louisville has abundant recreational facilities. Cherokee park, a 406-ac. woodland in the rolling hills east of the city, is a fine natural playground. Adjoining this tract is Seneca park which contains a golf course, a small lake and public playgrounds. Central park, in the heart of the city, has tennis courts, wading pools, a natural amphitheatre and other recreational facilities.

Louisville is a well-known sporting centre. Since 1875 it has been the scene of the annual Kentucky Derby, America's horse-racing classic, run at Churchill Downs. The Kentucky state fair, one of the oldest agricultural fairs in the U.S., features an annual horse show which almost rivals the derby in interest. The large armoury building and Freedom hall have been the scenes of numerous amateur and professional sporting events, including basketball, prize fights, wrestling matches and ice hockey. The Louisville Colonels, an American association baseball team until that league's suspension in 1962, had a history dating back to 1867 when the Louisville Eclipse team was organized. The city played an important part in the organization of the National league in 1876. Pete Browning, an early professional player, is credited with introducing the design for the "Louisville Slugger" baseball bat which is manufactured there. (T. D. C.)

LOURDES, a town of southwestern France famous for its Roman Catholic religious shrine. It is in the *département* of Hautes-Pyrénées, at the foot of the Pyrenees, on the banks of the Gave de Pau. Lourdes is 12 mi. S.S.W. of Tarbes on the main line of the railway from Toulouse to Bayonne. Pop. (1962) 15,691.

The origin of Lourdes is uncertain. From the 9th century onward it was the most important place in Bigorre, largely because of its famous fortress. In 1360 it passed by the treaty of Brétigny from the French to the English, who lost it to the French in 1406. During the religious wars the castle held out successfully against the Protestant troops. From the reign of Louis XIV to the beginning of the 19th century the castle was used as a state prison. After the visions of Bernadette Soubirous, between Feb. 11 and July 16, 1858, and the authorization by the pope of the cult of Our Lady of Lourdes, the quarter on the left bank of the Gave sprang up, and more than 2,000,000 pilgrims from all over the world annually visit the town. (See also *BERNADETTE, SAINT.*)

Lourdes is divided into an old and a new town by the Gave de Pau. The old quarter on the right bank surrounds a scarped rock, on which stands the fortress with its large square 14th-century keep. A tower of the 13th or 14th century, surmounting a gateway known as the Tour de Garnabie, is part of the old fortifications. The old quarter is united with the new by a bridge which is continued in an esplanade leading to the basilica, the church of the Rosary and the Massabielle grotto, where the Virgin Mary is believed in the Roman Catholic world to have revealed herself 18 times to Bernadette Soubirous. A statue of the Virgin stands on a rock projecting above the grotto, the walls of which are covered with crutches and other votive offerings; the spot is marked by a basilica built in 1876 above the grotto. The Byzantine church of the Rosary was built in front of and below the basilica from 1884 to 1889. Near the grotto are other caves, where prehistoric remains have been found. The underground basilica of Pope St. Pius X, large enough to hold 20,000 persons, was completed in 1958, the 100th anniversary of the visions, and was awarded the Grand Prix d'Architecture the following year.

The district has slate quarries; and the pastures support a breed of valuable Aquitaine cattle.

See René Laurentin, *Meaning of Lourdes* (1960); Fulton Oursler, *Happy Grotto* (1948). (Pr. L.)

LOURENÇO MARQUES, capital of Portuguese East Africa (Mozambique) and of the Lourenço Marques district, lies on the coast in the south of the country within 50 mi. of the boundary of the Republic of South Africa. It is situated on the north bank of the Espírito Santo river at its entrance to Delagoa bay fronting the Indian ocean, and is 395 mi. E. of Johannes-

A. D'ALPOIM GUEDES, MOZAMBIQUE

A PRIVATE HOME IN LOURENÇO MARQUES DESIGNED BY AMANCIO GUEDES

burg, S.Af., by rail. Pop. (1960, with suburbs) 183,798.

Lourenço Marques has a healthful climate. The mean annual temperature is 71° F.; the average in summer (November to April) is 78° F. and the heat is tempered by sea breezes. The average annual rainfall is 26 in., most of it in the summer.

The city is well laid out with many fine thoroughfares and modern buildings. From MacMahon square adjoining the railway station and docks, the main shopping and business streets (Rua Major Araujo, Rua Consiglieri Pedroso, Avenida da Republica) run parallel to the waterfront, from which at right angles the Avenida Joaquim de Aguiar leads to the imposing Mousinho de Albuquerque square. The square is flanked by the modern town hall and the Roman Catholic cathedral, a handsome modern building. There are Anglican and Methodist churches. The museum, housed in a building in the Portuguese Decorated style, contains collections (natural history, mineral, etc.) of Mozambique origin, and the military museum in the old fortress has many relics of the early colonial period. Schools include the imposing Lyceum Salazar adjoining the museum and two British educational institutions. The city and environs are notable for the work of the Portuguese architect Amancio Guedes, whose buildings in concrete (houses, flats, office blocks, factories) with their sculptural curves and mural decoration have affinities with those by Antonio Gaudi (*q.v.*). Lourenço Marques has excellent bathing beaches (notably the Polana with its shark-proof bathing enclosure), several excellent hotels, theatres and good recreational facilities. Since World War II it has become increasingly popular as a holiday resort for South Africans and Rhodesians. It has attractive botanical gardens near the city centre and a zoological park on the outskirts. The principal suburbs are Ponta Vermelha, Polana, Alto Mahé, Malhangalene and Somerschields.

Lourenço Marques is the seaport nearest to the Rand, the great gold mining and industrial centre of South Africa. The port is well equipped, with more than 1 mi. of concrete wharves, warehouses and electric cranes, a small dry dock and tugs. There are plants for loading ships with export coal (chiefly from Witbank, S.Af.) and a jetty for tankers at Matola, a few miles upriver. The great bulk of the traffic is that in transit with the Republic of South Africa, and most of the imports (foodstuffs, iron and steel, fuel oils, timber and livestock) figure also as exports, being forwarded to the Transvaal. The chief local import is wine and the chief exports by sea are coal, cotton, sugar, sisal, oilseeds, copra, hardwoods and fruit. Much of the trade is handled by British firms, although retail and native trade is largely in the hands of Indians. Industries include brewing and the manufacture of cement, pottery, furniture, footwear, soap, rubber and macaroni. A number of factories as well as a grain mill and timber yards are at Matola.

Several shipping lines schedule regular calls at Lourenço Marques. The main railway connections, of 3 ft. 6 in. gauge, are northwestward into Transvaal, S.Af., through Komatipoort; northward into Southern Rhodesia; and southwestward to Goba near

the Swaziland frontier. Motor roads run through Stegi, Swaziland to Durban (425 mi. S.S.W.); through Komatipoort, S.Af., to Johannesburg and Pretoria (357 mi. W.); and through Vila Luiza to Inhambane (388 mi. N.E.). Lourenço Marques airport, 5 mi. N.W. of the city, is served by international and local airlines.

Lourenço Marques (which derives its name from a Portuguese trader who first explored the region in 1544) was created a corporate town in 1887 and superseded the old town of Mozambique as the capital of Portuguese East Africa in 1907. The administrative district of Lourenço Marques had a population (1960) of 441,363 and an area of 4,009 sq.mi. For the history of the city see DELAGOA BAY. (N. C. P.)

LOUSE, a name commonly applied to small wingless insects parasitic upon birds and mammals and belonging to the orders Mallophaga (biting lice) and Anoplura (sucking lice). The word louse is also applied in a popular sense to many animals other than the true lice, *e.g.*, wood louse, fish louse (*see* CRUSTACEA), book louse of the insect order Psocoptera (*q.v.*), plant louse (*see* APHID) and bark louse. The true lice are hairy, flattened insects with short, three- to five-segmented antennae; the eyes may be reduced or wanting; and the tarsi are one- or two-segmented with strongly developed claws for clinging to their hosts. The eggs are attached to hairs, feathers or clothing, and the young lice are active as soon as they emerge. In structure and habits the immature lice resemble the adults, but they pass through several molts before reaching sexual maturity. When lice are numerous they cause great irritation to the hosts, upon whose bodies their whole life is passed.

The Mallophaga or biting lice constitute a separate order of insects, although they were previously classed as a suborder of the Anoplura. Biting lice attack birds chiefly, and some mammals however, they are not parasites of man, except perhaps accidentally and then only temporarily. They are rarely over one-fourth inch in length, and range in colour from whitish, through yellow, red and brown, to black (*see* MALLOPHAGA).

The order Anoplura (also known as the Siphunculata) is restricted to the sucking lice, all of which have extrusible mouthparts adapted for piercing and sucking. They live by imbibing blood or tissue fluids of mammals. None are parasitic on birds or reptiles. They are usually smaller than biting lice, all being less than one-third inch in length, and range in colour from whitish to yellow.

Sucking lice show distinct host specificity; that is, one species of louse is restricted to a species or a small group of species of hosts, usually within a single genus. Genera of lice are characteristic of certain families or related families of mammals. The louse family Pediculidae is peculiar to the primates (monkeys, apes, man), the Echinophthiridae to the marine carnivores (seals, sea lions, walruses) and the Haematopinidae to the rodents, rabbits and ungulates with very few exceptions. Vernon L. Kellogg has suggested that the presence of related lice on related groups of hosts is evidence of parallel evolution of parasites and hosts.

In addition to man and his domestic mammals a wide variety of wild mammals are infested by these insects, each host genus or species having its own characteristic parasites. A few hosts such as man, the domestic cow and some rodents have two characteristic species of sucking lice, but usually only one species is found on a host. Although sucking lice are largely restricted to old world primates, marine carnivores, rodents, rabbits and ungulates, several species are known from insectivores. The domestic dog is one of the few land carnivores parasitized by sucking lice. No species of Anoplura are known from monotremes (platypus, etc.), Australian marsupials (kangaroo, etc.), bats, elephants or cetaceans (whales, dolphins, etc.).

The best-known species of louse is the sucking louse of man *Pediculus humanus*, which infests the human race wherever modern hygienic practices have not been instituted. Its distribution is almost coextensive with that of the human race and the antiquity of this association is demonstrated by the presence of lice on ancient mummies from Egypt and the southwestern United States. This species has apparently been inherited by man from his remote primate ancestors. There are two varieties of the common human

louse, namely, *Pediculus humanus* var. *capitis*, the head louse, and *P. humanus* var. *corporis*, the body louse or "cootie." The human louse in heavy infestations may cause serious skin irritations, but far more serious is its role as the carrier from man to man of the pathogenic agents of epidemic typhus fever (see TYPHUS FEVER), trench fever of World War I and louse-borne relapsing fever (in contrast to tick-borne relapsing fever) (see RELAPSING FEVER). The terrible role of these diseases in the history of man is related by Hans Zinsser in *Rats, Lice and History* (1935).

Epidemic typhus fever has been a scourge whenever populations have been disrupted or concentrated by war, famine or floods and the attendant insanitary conditions.

The only other louse that infests man is the pubic or crab louse, *Phthirus pubis*, which is occasionally found in the hair of the armpits, in the eyebrows and beard as well as in the pubic regions. It is not known to be an important disease vector.

Related species of lice are *Pediculus schäffi* of the chimpanzee and *Phthirus gorillae* of the gorilla. The other lice from old world primates are included in the genus *Pedicinus*. *Pediculus mjobergi*, which is almost indistinguishable from the human louse, is recorded from several species of new world monkeys. It is generally considered that these monkeys have acquired the parasite by contact with man, although it may be established on wild monkeys. Some of the common lice of domestic animals are *Haematopinus suis* of the pig, *H. asini* of the horse, *H. eurytetrus* and *Linognathus vituli* of the cow and *L. setosus* of the dog.

In infestations on man DDT, lindane and other chemical dusts have proved effective insecticides for lice, and poisonous gases, chemical solutions and heat sterilization have been used to de-louse infested clothing. Chemical dips or sprays are used on infested domestic animals.

See INSECT; see also references under "Louse" in the Index.

See C. F. Craig and E. C. Faust *Clinical Parasitology*, thoroughly rev. by E. C. Faust and P. F. Russell, 6th ed., chap. 38 (1957); U.S. Department of Agriculture, "Insects," 1952 *Yearbook of Agriculture* (1952). (W. L. J.; X.)

LOUTH (CONTAE LUGHBHAIDH), a maritime county in the northeastern corner of the province of Leinster, Republic of Ireland, is bounded northeast by Carlingford lough, east by the Irish sea, southwest by Meath, northwest by Monaghan and north by Armagh (N.Ire.). The smallest county of Ireland, its area is 317 sq.mi., with a population (1961) of 67,378, of whom two-thirds are in towns, notably Dundalk and Drogheda, both of which are ports and industrial centres of Norman origin and long-standing significance.

Louth is one of the most interesting and varied of the Irish counties. It includes the hilly, scenically attractive Carlingford peninsula, named from the historic town of Carlingford (*q.v.*), which faces the lough of the same name. On the north side of the lough is the fine range of the Mourne mountains in County Down. The Carlingford peninsula has a remarkable double line of crests, formed of gabbros, with Carlingford mountain (1,935 ft.) as the highest point, and of granites which are smoother, more rounded hills such as Clermont Carn (1,674 ft.). There are granite basins between the gabbro crests. On the granites there are deep peat bogs, actively cut in recent years, but the gabbros form craggy slopes almost devoid of vegetation. The lowland fringe of the peninsula is made up of Carboniferous and Silurian beds (the latter on the Carlingford lough side), thickly plastered with glacial drifts. The rest of the county is part of the central lowland, and

ROSS E. HUTCHINS

HUMAN BODY LOUSE (*PEDICULUS HUMANUS*), ABOUT 20 TIMES ENLARGED

floored by Silurian strata, generally about 200 ft. above sea level but rising to more than 800 ft. in the Callow hills between the Dee and Boyne valleys. Everywhere a plastering of glacial drift occurs and away from the crest it gradually assumes the form of drumlins, though these merely diversify rather than dominate the lowland of County Louth. Only one-eighth of the area is unimproved agricultural land, of which the largest continuous stretch is in the mountains of the Carlingford peninsula. Glacial drifts have given varied soil and drainage conditions, but many of the small patches of peat bog have long been cleared and the land used for pasture or even crops such as potatoes.

History.—Louth was the scene of some of the great mythical or semimythical exploits of the hero Cú Chulainn, perhaps about the beginning of the Christian era. It was the scene of the *Táin Bó Cúailnge* or "cattle raid of Cooley," which gave rise to the seven years struggle between the men of Ulster and those of Connaught.

The kingdom of Oriel was established in the 4th century, comprising Monaghan, Louth and Armagh, and Louth was for many centuries associated with Ulster rather than with Leinster. The kingdom of Oriel was finally wiped out by Anglo-Norman invaders. In 1185 Prince John annexed to the crown the barony of Louth. He established Theobald de Verdun (or Verdon) as lord of Dundalk and Roger de Pippard as lord of Ardee. Under Richard II Louth was included in the English Pale, and it remained part of the small area which the Dublin government could still effectively rule during the later middle ages. The towns of Drogheda and Dundalk were of considerable importance, and parliaments were sometimes held in them as well as in Dublin. In Tudor times, when Ulster had become the core of resistance to extending English rule, Dundalk was a frequent marshaling place for armies which advanced north through the Dundalk gap. Like other parts of the Pale, Louth had its own rather turbulent landed nobility, many of whom were ruined and replaced during the 17th century.

There are some fine relics of the monastic period of the Celtic Church, notably at Mellifont and Monasterboice. Castles of the Anglo-Norman phase are relatively numerous and include some small ones apparently intended for the defense of the Pale. Of the towns, Ardee, Drogheda and Dundalk possess Norman charters, but Collon and Dunleer are apparently later foundations.

Administration and Economy.—A county council meets at Dundalk, the county town, and there is a county manager. Drogheda (pop. [1961] 17,085) and Dundalk (19,790) are urban districts, and Ardee is administered by town commissioners. The county returns three members to *dáil Éireann*.

Agriculturally, the county shows the transition from the small-

BORD FÁILTE ÉIREANN

RUINS OF MELLIFONT, THE FIRST CISTERCIAN ABBEY IN IRELAND, FOUNDED 1142

farm regimes of Counties Down and Armagh to the large grazing farms of County Meath. In the Carlingford peninsula many of the farms are of 30–50 ac., with somewhat intensive production of a mixed type. Much of the land in the peninsula is used for crops, notably potatoes, oats, barley and turnips, with lambs, young cattle, poultry and butter as the main cash staples. Through the lowland from the Dundalk area southward there is a gradual increase of farm size: near Dundalk, for example, there are medium-sized holdings with cattle grazing and arable cropping, largely for oats, but farther south toward Drogheda there are large grazing farms. In the whole county over one-quarter of the improved land is used for crops, the biggest of which is wheat, followed by barley, potatoes, oats and turnips.

Dundalk and Drogheda are on the main railway line from Dublin to Belfast. Dundalk has a wide range of industries including brewing (a new brewery producing lager was opened in 1962); mineral water (soft drink) production, grass seed purifying, milling and bacon curing, with tobacco and textile works—the last providing a variety of cotton and linen goods. Larger modern factories have been established for the footwear industry. Drogheda has a line of factories along the Boyne, of which several use the port; they include shoe factories, a chemical manure works, various mills for grain, and linen mills. On the Boyne outside Drogheda there is a large cement works. Ardee is a quiet market town in a fertile agricultural area. (T. W. Fr.; Hu. S.)

LOUTH, a market town and municipal borough in the Parts of Lindsey, Lincolnshire, Eng., lies 26 mi. E.N.E. of Lincoln by road on the river Lud where it flows out of the Wolds. The Greenwich meridian passes through the town. Pop. (1961) 11,556. Louth is the chief marketing centre for agricultural and general produce in north Lincolnshire, and its weekly cattle market is the busiest in the county. Near the town hall (1853) are the chief market buildings, the Market hall (1866–67) and the Corn Exchange (1854). The town's industries (e.g., the making of agricultural machinery) are mainly connected with agriculture and horticulture; but plastics and packaging materials are also produced.

Louth owed its early prosperity to the nearby Cistercian abbey founded in 1139 by Alexander, bishop of Lincoln. It received its charter in 1551 from Edward VI. Among the pupils at King Edward VI grammar school (first mentioned in 1276) where John Smith, an early settler of Virginia; the poet Alfred, Lord Tennyson, and his brother Charles; and Sir John Franklin, discoverer of the northwest passage. The Perpendicular parish church of St. James was built between 1500 and 1515. About 1 mi. W. of the town is the 40-ac. park of Hubbards hills. (WA. H.)

LOUTHERBOURG (LUTHERBURG), PHILIPPE JACQUES DE (1740–1812), landscape painter, engraver and especially successful theatrical scene designer of Polish origin who became a naturalized Englishman, was born at Fulda, Ger., on Oct. 31, 1740. He received his first training under his father, a miniature painter. Later, about 1755, he worked at Paris under Charles van Loo and Francesco Casanova. He was received into the academy in 1767 and exhibited battle scenes, landscapes and marine paintings at the Salon, where he won the praise of Diderot who considered him as an inferior Vernet with an admixture of Berghem. In 1771 he went to London with an introduction to David Garrick who paid him £500 a year as his regular adviser on scenic effects at Drury Lane theatre from 1773. In 1781 he turned his talents to the Eidophusikon, an elaborate moving panorama combined with dramatic lighting effects and music, which enjoyed considerable success. Later he retired to Hammersmith where he practised as a faith healer. He also devised a system for reproducing paintings in colour which occasionally deceives even modern critics. He died on March 11, 1812.

Loutherbouurg had a marked talent for ingenious dramatic effects in oil paintings, but as he seldom referred to nature, his theatrical work was probably better adapted to his abilities than landscape painting.

See W. T. Whitley, *Artists and Their Friends in England 1700–1799*, vol. 2 (1928); E. K. Waterhouse, *Painting in Britain 1530 to 1790* (1953). (F. J. B. W.)

LOUVAIN (Flem. LEUVEN), a town of Belgium on the Dyle (Dijle) river in the province of Brabant, of which it was the capital from 1190 until the rise of Brussels, 16 mi. to the east by road. Pop. (1961) 32,524. Local tradition attributes the establishment of a camp there to Julius Caesar, but Louvain only became important in the 11th century as a residence for the counts of Louvain, afterward the dukes of Brabant. The name is derived from the Low German *loo* ("bushy height") and *veen* ("swamp"). In 1356, at the time of the famous *Joyeuse Entrée* (q.v.) of Wenceslas, the principal charter of Brabant, Louvain had a population of at least 50,000 and was a centre of the cloth trade. The guild of weavers numbered 2,400 members. The old walls, 4½ mi. in circumference, have been replaced by boulevards. Soon after the *Joyeuse Entrée* a feud began between citizens and patricians. After a struggle of more than 20 years' duration, the White Hoods, as the citizens called themselves, were crushed. In 1379 they massacred 17 nobles in the town hall, but this brought the vengeance of the duke, to whom in 1383 they made the most abject surrender. Many weavers fled to Flanders and England, the duke took up residence in the strong castle of Vilvorde, and Brussels prospered at the expense of Louvain.

What it lost in trade it partially recovered as a seat of learning, for in 1425 Pope Martin V founded at Louvain the first university in the Netherlands, which has always been renowned for its Catholic teaching. From 1432 the university occupied the old Cloth Workers' hall, a building dating from 1193 and many times restored, with long arcades and graceful pillars supporting the upper stories. In the 16th century there were about 6,000 students and 50 colleges attached to the university; there are now seven faculties and 21 affiliated institutes with a student membership exceeding 13,000. The aula and the university library were burned in the German invasion of 1914. A new library (designed by the U.S. architect Whitney Warren) was built (1921–28) with American funds, and books and fittings were donated by many nations. It was again destroyed by fire during the German attack in May 1940 but has been restored and restocked with about 800,000 volumes.

The town hall, one of the richest examples of pointed Gothic, was built by Mathieu de Layens, master mason (1448 to 1463), of three stories, each with ten pointed windows facing the square. The church of St. Peter, originally dating from the early 11th century, was twice destroyed before being restored as a Gothic structure (1425–97); it was again damaged in World Wars I and II. It has seven chapels, in two of which are fine pictures by Diener Bouts, formerly attributed to Memling. Much of the iron and brass work is by Quentin Massys. Other interesting buildings include the churches of Ste. Gertrude, St. Quentin, St. Michael, St. Jacques, the two *béguinages* and the "Round Table" (former meeting place of merchant guilds).

Industries include flour milling, brewing and radio valve (tube) manufacture. Mirrors are made, mainly for export, and there is a bell foundry. (R. M. Ax.)

LOUVER (LOUVRE, LUFFER), in architecture, was originally a lantern or cupola built on the ridge of the roof of the great hall of a medieval house to let out the smoke. The term was later generally applied to a system of slanting boards, sheets of metal or glass, or other material, so arranged as to permit the passage of air while restricting the view, the sun, rain water, or any combination thereof. Three large adjustable horizontal louvers were used in each room of the Ministry of Education building in Rio de Janeiro (Oscar Niemeyer, 1936) as sun protection. In modern adjustable vertical aluminum louvers, one story high (repeated on each story) serve as sun protection on all four sides of the building (American Life Insurance building, New Orleans, La. (Skidmore Owings and Merrill, 1951). Since louvers are practical and usually attractive they have become a popular feature of temporary architecture. (H. M.)

LOUVET (DE COUVRAY), JEAN BAPTISTE (1760–1797), French man of letters prominent as a Girondin during the Revolution, was born in Paris on June 12, 1760, a poor merchant's son. For a few years he used the additional name "Couvrai" or "de Couvray" to distinguish himself from other Louvets. He was working for a bookseller when he won the

with a licentious novel, *Une année de la vie du chevalier de Faublas*, 5 parts (1786–87), supplemented by *Six semaines de la vie* . . . 2 volumes (1788). Later completed with *La Fin des amours du chevalier de Faublas*, 6 volumes (1790–91), the work was many times reprinted as *Les Amours* . . . or as *Les Aventures du chevalier de Faublas*. A jeweler's wife, Marguerite Denuelle, whom he abducted and to whom he gave the name Lodoiska, shared in all the future vicissitudes of his life.

At Nemours when he heard that the Parisians had stormed the Bastille (July 1789), Louvet was the first to sport the tricolour cockade there. He was at Versailles when the Parisian marchers arrived to take the royal family back to Paris (October); and when J. J. Mounier denounced these proceedings, Louvet defended them in a pamphlet. A member of the Jacobin club, he yet continued his frivolous writing for some time. In Dec. 1791, however, he presented to the Legislative Assembly the petition from the Lombards section of Paris which was answered by the decree of Jan. 2, 1792, against the king's brothers and other émigrés. Elected to the Jacobins' correspondence committee, he launched a poster newssheet, *La Sentinelle*, in March 1792, to combat the court's policy. This newssheet was soon subsidized by the ministry of the interior, then under J. M. Roland, and its success helped Louvet's election to the Convention as deputy for Loiret. By now a member of Madame Roland's circle, Louvet took the side of the Girondins (*q.v.*) in the Convention: his attack on Robespierre (Oct. 29, 1792) was sensational; and to Robespierre's reply (Nov. 5) he retorted with a pamphlet, *À Maximilien Robespierre et à ses royalistes*, full of misrepresentations. At Louis XVI's trial he voted for the death sentence with a suspension. On the overthrow of the Girondins (June 2, 1793), he went into hiding in Paris before joining his friends in Caen. After withdrawing to Brittany and then by sea to the Gironde, he went secretly to Paris in Dec. 1793 but next took refuge in Switzerland until the Thermidorian reaction allowed his return to Paris in Oct. 1794. Readmitted to the Convention on March 8, 1795, he remained a republican while other Girondins turned royalist. He protested against the excesses of the reaction after the rising of Fauriel (May 1795). Under the Directory he sat for Haute-Vienne in the council of 500. Louvet died in Paris on Aug. 25, 1797. (A. So.)

LOUVOIS, FRANÇOIS MICHEL LE TELLIER, MARQUIS DE (1639–1691), French statesman, secretary of state for war and the most influential minister of the middle period of Louis XIV's reign. He was born in Paris and baptized on Jan. 18, 1639, of a family of modest origin, being the son of Michel Le Tellier (*q.v.*), whose unpretentious manner did much to induce Louis XIV to accept the young man's services. Granted the *survenance* or right of succession to his father's secretaryship of state for war in Dec. 1655 (during Cardinal Mazarin's ministry for Louis XIV), Louvois was authorized to sign himself secretary of state in Feb. 1662, soon after the beginning of the king's personal Marriage (March 1662) to Anne de Souvré, marquise de Montpensier, raised him in the social hierarchy.

In strictly military matters Louvois acknowledged the superiority of the great Turenne and for a time showed great humility in matters to him, though his authoritarian temperament rebelled against the need for such deference. In Feb. 1672, however, Louvois was admitted to the king's upper council, with the title of minister of state; and then his strong personality could assert itself. When Louis XIV opened his war against the United Provinces of the Netherlands in March 1672 (see DUTCH WARS), alterations between Louvois and Turenne ensued. A notable one arose over the right to be addressed as *Monseigneur* instead of *Monsieur* in official letters. When Louvois persuaded the king that secretaries of state, writing on the king's behalf, should no longer write *Monseigneur* to dukes or to persons enjoying the rank of "foreign prince" at the French court, Turenne, a "foreign prince" of the house of La Tour d'Auvergne, protested so forcefully that he retained the distinction for his house; but Louvois conversely obtained that secretaries of state should themselves be addressed as *Monseigneur* except by dukes or princes. Turenne's death in battle (1675) and the great Condé's retirement in the

same year left Louvois free to conduct the war in his own way. Thenceforward it was usually he who composed the king's directives to the generals.

Le Tellier, who had provisionally resigned his own secretaryship of state in 1667, resigned it definitively in 1677, on becoming chancellor of France. Louvois thus became sole secretary of state for war. Year by year his influence grew till he emerged as the king's indispensable adviser, prime minister in all but name for his last ten years. From the beginning of Louis XIV's personal rule, however, Louvois and J. B. Colbert (*q.v.*) had been rivals for the king's favour—although not to the extent alleged by malicious contemporaries or to the detriment of their work. Even so, some difficulty arose over the secretaryship of state for foreign affairs. When Hugues de Lionne died (1671), his destined successor, Simon Arnauld de Pomponne, was absent from France as ambassador to Sweden; and Louvois, put in temporary charge of foreign affairs, acquired such a taste for them that he continued to correspond directly with ambassadors even when Pomponne had taken up his duties. Pomponne complained, and angry disputes took place in the king's council. Louvois and Colbert, who also disliked Pomponne, together prevailed at last on the king to dismiss him; but Louvois was not pleased to see the post taken by Colbert's brother, Charles Colbert de Croissy.

Louvois maintained his influence over the king largely because he was always ready to second his schemes for aggrandizement (whereas Colbert never stopped arguing for economies) and constantly proposed military solutions for problems. Moreover, though he never commanded an army in the field, he had a remarkable talent for military administration. Since his father had already reorganized the army, Louvois had nothing much to create; but he knew how to maintain discipline and to ensure that armies were never without munitions, rations or pay. In 1688, when a new European war was breaking out (see GRAND ALLIANCE, WAR OF THE) he introduced a type of compulsory military service: for every levy of troops, every *généralité* in the kingdom was to elect a quota of unmarried men between the ages of 20 and 25, who would then be equipped with arms and clothing at the expense of their parishes and enrolled in "provincial militias." The system of election, however, soon gave rise to abuses and was replaced by the drawing of lots.

The duc de Saint-Simon, author of the *Mémoires*, recognized the capacity of Louvois but resented his part in the humiliation of the dukes and described him as "a haughty man, brutal in all his ways." Brutality was indeed a salient characteristic of Louvois. During the Dutch War he received complaints about the cruel treatment of civilians by French soldiers, but wrote to the general in command: "I pray you not to relax your ruthlessness, but to push things forward, in this respect, with all imaginable vigour." He also played a part in promoting the system of *dragonnades* for the harassing of Huguenots before the revocation of the Edict of Nantes. Louvois died at Versailles on July 16, 1691. A *Testament politique de Louvois*, published in 1695, is of doubtful authenticity. His bad handwriting makes his manuscripts, in the archives of the Ministère de la Guerre, very hard to decipher.

LOUÏS, PIERRE (pseudonym of PIERRE LOUIS) (1870–1925), French novelist and poet who sought to express pagan sensuality with stylistic perfection. He was born in Ghent, of French parents, Dec. 10, 1870, and was educated in Paris at the École Alsacienne, where he met André Gide. He frequented Parnassian and Symbolist circles and was a friend of Debussy. He founded *La Conque* (1891), one of the first reviews to publish poems by Paul Valéry (*q.v.*). His *Chansons de Bilitis* (1894), prose poems about Sapphic love purporting to be translations from the Greek, deceived even experts. *Aphrodite* (1896), a novel depicting courtesan life in ancient Alexandria, made him famous. His best work is *La Femme et le Pantin* (1898), a psychological novel set in Spain. LouÏs spent his last years in semiseclusion, and died in Paris, June 4, 1925.

LOVAT, SIMON FRASER, 11TH BARON (c. 1676–1747), Scottish Jacobite, chief of clan Fraser, noted for his violent feuds and changes of allegiance, was the eldest surviving son of Thomas, fourth son of the 7th Lord Lovat. Educated at King's college, Aberdeen, Simon combined culture with barbarity—his main fascination for posterity. His ambition was "to be the greatest Lord Lovat that ever was," and his endeavours to win the estates and title largely explain his tortuous career. He persuaded the weak 9th Lord Lovat to settle the liferent of his estates on Thomas Fraser in 1696, but the destination of the estates had already been settled in favour of Lovat's daughters. On the death of the 9th lord, Simon Fraser tried to solve this problem by a politic marriage with the eldest daughter, Amelia, but his design failed. He then forcibly married the dowager Lady Lovat and thus incurred a long and bitter feud with her kinsmen, the Murrays of Atholl. As a consequence in 1698 Simon was tried and sentenced to death, but through the intercession of the earl of Argyll he won a pardon from William III. It was not a complete pardon, however, and in 1701 Fraser was tried for the "rapt" of Lady Lovat. For failing to stand trial he was once more outlawed. After spending some time in London he crossed to France where he soon made contact with the court of the exiled Stuarts.

In 1702 young Amelia Fraser of Lovat married Alexander Mackenzie, son of Lord Prestonhall; the honours of Lovat were confirmed to her, and in an unsuccessful bid to win the affections of clan Fraser her husband assumed the designation of Mackenzie of Fraserdale.

Simon Fraser returned to Scotland in 1703 on a Jacobite mission which he betrayed to the duke of Queensberry, head of the Scottish ministry. Lovat's treachery leaked out and on his return to France he was held captive for ten years, first at Angoulême and then at Saumur. He escaped and returned to Scotland in 1715 where he found that Fraserdale had joined the Jacobite rebels. This decided Lovat's allegiance for the time and he rendered good service to the government. For this he was pardoned and granted a liferent of the coveted estates. Not content with this he strove to gain the full title, aided by the eminent lawyer Duncan Forbes of Culloden. To enlist government support Fraser co-operated with Gen. George Wade in his efforts to pacify the Highlands after 1725, but at the same time he did much to revive the flagging spirit of clanship. He received the title in 1730 but did not gain complete possession of the estates until 1733.

Lovat hoped for greater rewards if the Stuarts were restored, and he was largely instrumental in founding (1739) the Jacobite association. In 1740 he was secretly created duke of Fraser by James, the Old Pretender. But Prince Charles Edward's failure to bring arms and troops with him in 1745 nonplussed Lovat. He forced his son Simon to join the rebels while he himself pretended loyalty to George II. After the Jacobite victory at Prestonpans, however, Lovat openly espoused the Stuart cause although he played no appreciable part in the rebellion. After the Jacobite defeat at Culloden he urged Charles Edward to continue the campaign; but all was lost and Lovat was eventually captured. He was condemned by the house of lords on March 18, 1747, and, with a great show of bravado to the last, he was executed on April 9, 1747, on Tower hill, London.

LOVEBIRD: see PARROT.

LOVEJOY, ELIJAH PARISH (1802–1837), U.S. abolitionist, was born at Albion, Me., on Nov. 9, 1802, and graduated at Waterville (now Colby) college in 1826. The following year he moved to St. Louis, Mo., where he established a school and entered journalism. Later he began to publish a religious paper called *The Observer* in which he strongly condemned slavery and recommended gradual emancipation. A letter in 1835 signed by a number of the important men of St. Louis requested him to mod-

erate the tone of his editorials. He replied in an editorial reiterating his views and his right to publish them. Threats of mob violence forced him to move his press across the Mississippi river to Alton, Ill. There his press was destroyed by mobs several times in one year, and on the night of Nov. 7, 1837, when a mob attacked the building, Lovejoy was killed in its defense. The news of his death stirred the people of the north profoundly and led greatly to the strengthening of abolitionist sentiment.

LOVELACE, RICHARD (1618–1657), described by Edward Phillips in *Theatrum Poetarum* (1675) as "Souldier, Gentleman & Lover, and a fair pretender to the Title of Poet," came of an old Kentish family but was probably born in Holland, where his father was in the Dutch military service, in 1618. He was educated at Charterhouse and at Gloucester hall, Oxford, when, according to Anthony à Wood's *Athenae Oxonienses*, he was "accounted the most amiable and beautiful person that ever eye beheld." After leaving Oxford he retired "in great splendor to the Court." At 16, according to Wood, but possibly a little later, he wrote *The Scholars*, a comedy acted at Whitefriars, of which the prologue and epilogue survive. He took part in the two expeditions to Scotland (1639–40) and during the second wrote *The Soldier*, a tragedy never acted and now lost.

Returning to his estates in Kent, Lovelace, who had torn up a disloyal petition at the quarter sessions at Maidstone, was chosen to present (1642) a royalist petition to a hostile house of commons. For this he was imprisoned in the Gatehouse, London, where he wrote "To Althea, from Prison." Released "upon good Security" after about seven weeks, he probably went to Holland. He passed much of the next four years abroad and was wounded fighting for the French against the Spaniards at Dunkirk in 1646.

On Oct. 26, 1647, with Thomas Rawlins and Peter Lely, Lovelace, now a colonel, was admitted to the freedom of the Painters company—an unusual and significant honour. In 1648 he was again imprisoned. James Thompson, a lawyer, writing on Oct. 26, said that soldiers searching for Lovelace's brother Francis seized "divers Delinquent Jewells" in Richard's cabinet and that the incensed poet, taking it upon him "stiffly to argue property," was arrested on the pretense that something had been found in his papers (see *The Oxinden and Peyton Letters*, 1642–70). During his imprisonment, Lovelace prepared *Lucasta* (1649) for the press. Wood identified *Lucasta* with one Lucy Sacheverell, but if a real person, as is probable, she is as likely to have been a Lucas.

Lovelace continued to write commendatory verses for various publications, a practice he began at 20. Wood says he died in misery and poverty in 1658 and was buried in St. Bride's church, London, but an elegy on him was printed in 1657. He had certainly sold much of his estates, and he who was noted for generosity to ingenious men was himself helped in need by Charles Cotton, but none of the elegies supports John Aubrey's story of his unhappy death.

That Lovelace was himself planning a second volume is shown by Eldred Revett's lines "On his second poems," but *Lucasta. Posthume Poems of Richard Lovelace Esq.* (1659) was edited by his brother Dudley, assisted by Revett, and includes *Elegies*, dated 1660.

Lovelace was the friend of musicians, painters and writers such as Henry Glapthorne, who named his daughter Loualis after him, James Howell, Alexander Brome, Andrew Marvell and John Hall, the last of whom liked people who were "celebrated for some excellent endowment," but was so far from being a royalist that *Mercurius Elencticus* (1648) asked if he could be a fit associate for such ingenious and candid souls as Lovelace. John Sherburne, James Shirley or Thomas Stanley, who includes the other three in his "Register of Friends." Lovelace was scholarly and cultured, interested in languages, literature, music, painting, hunting, falconry and everything thought befitting a gentleman.

In his poems Lovelace generally follows the "conceited" fashions of his time, though his best songs owe much to a simplicity of thought and diction which possibly led Sir Walter Scott, when misquoting "To *Lucasta*, Going to the Warres" in *The Talesman*, to claim it for the earl of Montrose. Obvious criticism is summed up by John Ferriar's "Lovelace strikes, by fits a note divine," but

even when Lovelace's verses are only exercises in ingenuity there is audible the voice of one whose conversation was "witty and incomparably graceful," and who succeeded in giving to plain emotions the utterance that is most effective and memorable in song.

See *The Poems of Richard Lovelace*, with an introduction by C. H. Wilkinson, 2 vol. (1925). (C. H. Wn.)

LOVELL, FRANCIS LOVELL, VISCOUNT (1454-1487?), English politician and supporter of Richard III, was a son of John (d. 1465), 8th Baron Lovell of Tichmarsh, an adherent of Henry VI. Francis was knighted by Richard, duke of Gloucester (later Richard III), during the Scottish expedition of 1480 and was created viscount in Jan. 1483. After the death of Edward IV in 1483 he was made chief butler of England in May; chamberlain of the household from June 1483 to August 1485; and at Richard's coronation in July 1483, he bore the third sword. As one of Richard's most trusted ministers he was denounced in William Collingbourne's celebrated couplet:

The catte, the ratte, and Lovell our dogge
Rulyth all Englande under a hogge.

Lovell fought for Richard at Bosworth and after the battle fled to sanctuary at Colchester. The following year he escaped to organize a dangerous revolt in Yorkshire. When this was put down, he escaped to the Netherlands, where Margaret of York helped him. He accompanied John de la Pole, earl of Lincoln, and Martin Schwartz, with a force of men to Ireland in May 1487 in support of Lambert Simnel's imposture. They then crossed to England and were defeated by Henry VII's forces at Stoke in June 1487. Lovell was seen fleeing after the battle, but was never heard of again. In 1708 there was found in a secret vault at Lovell's house at Minster Lovell, Oxfordshire, the skeleton of a man seated at a table, on which were a book, paper and a pen. It is thought that Lovell had hidden himself there and died of starvation.

See J. H. Ramsay, *Lancaster and York*, vol. ii (1892); J. D. Mackie, *The Earlier Tudors: 1485-1558* (1952); *Notes and Queries*, vol. 1, 2nd series (1856) and vol. 10, 5th series (1878). (A. R. M.)

LOVETT, WILLIAM (1800-1877), English Chartist leader mainly responsible for the drafting of the People's Charter (see CHARTISM), was born at Newlyn, near Penzance, on May 8, 1800. He was apprenticed to the trade of ropemaking, but turned to carpentry and moved to London in 1821. He established himself as a cabinetmaker, not without difficulty, but spent all his available spare time in self-education, particularly in the study of economics and politics. He was a follower of Robert Owen and in 1829 became honorary secretary to the British Association for the Promotion of Co-operative Knowledge, a seminal organization in the development of working-class radicalism. After losing all his savings in the failure of an attempt to set up a shop he became storekeeper of the London Co-operative association. He met many London radicals, and was one of the group that sponsored *The Poor Man's Guardian* and later the London Workingmen's association (1836). It was this body that launched the People's Charter in 1838. Lovett was a zealous and high-minded Chartist, who found it impossible to work with or under the leadership of Feargus O'Connor (*q.v.*). His role in Chartism, therefore was limited, but he was secretary of the Chartist convention of 1839 and was arrested after Chartist disturbances in Birmingham when the convention moved there in May. He was sentenced to 12 months' imprisonment in Warwick jail. While there he wrote jointly with John Collins, his fellow prisoner, a little book *Chartism: A New Organization of the People*. Lovett now identified political advance with education. He had always disliked and despised talk of political force, and he put his trust increasingly in voluntary "self-improvement." In 1841 he created the National Association for Promoting the Political and Social Improvement of the People, to which he devoted most of his energies. He kept open a "national hall" until 1857, after which he wrote a number of textbooks designed for working-class students. He also wrote his autobiography, published in 1876. He died in London on Aug. 8, 1877. (A. BRI.)

LOW, SIR DAVID ALEXANDER CECIL (1891-1963), one of the most outstanding of modern political cartoonists

REPRODUCED BY PERMISSION OF LONDON "EVENING STANDARD"

(LEFT) LOW, PHOTOGRAPHED AT HIS DRAWING BOARD, (RIGHT) "VERY WELL, ALONE," A LOW CARTOON THAT APPEARED JUNE 18, 1940, DURING THE BATTLE OF BRITAIN

and caricaturists, was born at Dunedin, N.Z., on April 7, 1891, of Scottish and Irish parentage. Briefly educated at Christchurch High school and a self-taught artist, he was already contributing cartoons to a local weekly paper at the age of 11. At 17 he set out as a full-time freelance artist, combining this work from 1911 with a post on the *Bulletin* of Sydney, Austr. Having acquired a certain notoriety with some highly successful and impudent cartoons of Australia's Labour prime minister "Billy" Hughes (*The Billy Book*, 1918), Low was invited to England by the *Daily News* in 1919. He found himself on the *Star*, however, remaining there until 1927, when he joined the *Evening Standard* at the invitation of Lord Beaverbrook. Thriving in opposition to this paper's right-wing political views—a situation cleverly encouraged by its proprietor—Low produced work perhaps unequalled in this field. He reached his peak with the political cartoons of the years before and during World War II which earned him world fame and the especial hatred of Adolf Hitler. His immortal fictional character "Colonel Blimp" also was born in the *Evening Standard*. Of all newspaper cartoonists, Low came to terms most successfully with the limitations of topicality, newsprint and the reader. The melodramatic simplicity of his conception and the almost oriental facility of his brushwork combined with telling effect, especially when dealing with the black and white issues of fascism and oppression. Much work on these themes is contained in *The Years of Wrath* (1949). Thirty Low collections were published, from *Low's Annual* (1908) to *The Fearful Fifties* (1960). Low's *Autobiography* appeared in 1956. He left the *Evening Standard* for the *Daily Herald* in 1950—a flirtation as unsatisfactory as it was short-lived. In 1953 he joined the *Guardian*, with which he had long been associated, contributing three cartoons weekly from semi-retirement. He was knighted in 1962 and died in London on Sept. 19, 1963. (RD. S.)

LOW, SETH (1850-1916), U.S. municipal reformer, university builder and philanthropist, was born in Brooklyn, N.Y., Jan. 18, 1850. He graduated as valedictorian of Columbia college in 1870, thereupon entering his father's prosperous importing business and becoming a leader in the silk trade.

Low was twice elected mayor of Brooklyn, and his administration (1882-85) was characterized by civil service reform, administrative efficiency, public school reorganization and advocacy of home rule, all of which attracted national attention.

Low served as president of Columbia from 1896 to 1901, transforming Columbia from a small college on a crowded city block to a large university on an impressive campus on Morningside heights. He gave coherent form to the university spirit, organized the university council, the graduate faculties of philosophy and pure science, and by absorption or alliance brought the College of Physicians and Surgeons, Barnard college, Teachers college and other important components more closely into the Columbia university system. He set an example of philanthropy by his gift of the imposing central building on the new campus, by his support of professorships and by his aid, through Barnard, of education for women. In 1899 he was a delegate to the first Hague Peace conference.

Elected mayor of greater New York in 1901, Low eliminated plaguing paternalism and demonstrated municipal administration

on business principles. Failing re-election in 1903, he nonetheless continued outstanding public service, furthering education for Negroes as chairman of the trustees of Tuskegee institute from 1907 until his death, and labour-management relations as arbitrator in major disputes. He served also as president of the National Civic federation and the New York Chamber of Commerce.

Low died Sept. 17, 1916, at his home in Bedford Hills, N.Y.

LOWDEN, FRANK ORREN (1861–1943), U.S. lawyer and politician, governor of Illinois from 1917 to 1921, was a nationally prominent advocate of reforms in governmental administration and of improvements in the social and economic condition of farmers. He was born at Sunrise City, Minn., Jan. 26, 1861, but from the age of seven grew to manhood in Hardin county, Ia. There he worked as farm hand and schoolteacher, and graduated from the state university in 1885. Quick success as an attorney followed his move to Chicago in 1886 and his graduation the next year from the Union College of Law. His marriage in 1896 to Florence, daughter of George M. Pullman (q.v.), had an important influence on his career. During the next decade, while counseling, directing or organizing business corporations, he established his home at "Sinnissippi," an estate near Oregon, Ill. There and on his Arkansas plantations he experimented with field crops, livestock and forestation.

His long apprenticeship in Chicago politics ended in 1904 in an unsuccessful bid for the Republican gubernatorial nomination. From then to 1912 he was a moderately progressive national committeeman of his party. In congress, 1906–11, he sponsored measures to improve the foreign service and benefit agriculture.

As governor of Illinois, in addition to vigorously upholding Pres. Woodrow Wilson's war policies, Lowden initiated a widely-imitated state budgetary and administrative structure, centralized under executive control. Although his political career climaxed in a deadlock with Leonard Wood for the Republican presidential nomination in 1920, which resulted in their both being by-passed in favour of Sen. Warren G. Harding, Lowden declined the vice-presidential nomination in 1924, sought the presidential nomination in 1928, and, as "Sage of Sinnissippi," often advised politicians and political scientists until his death at Tucson, Ariz., March 20, 1943.

Following 1920, however, farmers' welfare was Lowden's principal concern. In frequent speeches and articles and through many organizations he championed marketing co-operatives, purebred dairy cattle, and improved methods of tillage. After 1925, with the agricultural depression deepening, he supported the McNary-Haugen bills for extending federal aid to farmers. The Domestic Allotment law of 1936 embodied his proposal, made seven years previously, to tie in government assistance with soil restoration.

Lowden's papers are in Harper Library, The University of Chicago.

See William T. Hutchinson, *Lowden of Illinois*, 2 vol. (1957).

(W. T. HN.)

LOWE, SIR HUDSON (1769–1844), English general and governor of St. Helena at the time of Napoleon's exile, was born at Galway in Ireland on July 28, 1769. He was an ensign in the East Devon militia in his 12th year and in 1787 was gazetted ensign in the 50th Foot. Throughout the war with France after 1793, Lowe was continually on active service, holding many important commands. He was knighted in 1814. Charged with the duties of quartermaster general of the army in the Netherlands in 1814–15, he was about to take part in the Belgian campaign when he was transferred to the command of the British troops at Genoa. While in the south of France he received (Aug. 1, 1815) news of his appointment to the position of custodian of Napoleon I. Soon after he was made governor of St. Helena, the place of the emperor's exile, and he arrived in the island in April 1816.

The appointment was considered by many people, including the

duke of Wellington, as unsuitable. Lowe was a man of little education and no imagination. The responsibility of his position weighed on him unduly with the result that he was excessively punctilious in carrying out his orders. Friction soon arose between Lowe and his prisoner. The news that rescue expeditions were being planned by the Bonapartists in the United States led to the enforcement of stricter regulations in Oct. 1816. Nevertheless Lowe recommended that the government allowance of £8,000 a year to the Longwood household should be increased by one-half. After the death of Napoleon in May 1821, Lowe returned to England and received the thanks of George IV, although his treatment of Napoleon aroused widespread criticism. He commanded the forces in Ceylon (1825–30), but was not appointed to the governorship when it fell vacant in 1830. Lowe died in London on Jan. 10, 1844.

LOWELL, ABBOTT LAWRENCE (1856–1943), U.S. educator, president of Harvard university from 1909 to 1933, was born in Boston, Mass., on Dec. 13, 1856. He graduated from Harvard, A.B. 1877, LL.B. 1880, and practised law in Boston for 17 years before turning to teaching at Harvard. In 1909 he succeeded Charles William Eliot as president. Within a few years he had realized a new scheme of "concentration and distribution" to modify Eliot's "free elective" system, devised general examinations to de-emphasize isolated course-credits, and set up a tutorial plan to supplement undergraduate lectures. During his administration Harvard more than doubled student enrollments, nearly trebled the faculty, increased endowments from \$22,000,000 to \$130,000,000, and added new professional schools of architecture, business administration, education and public health. Beginning in 1930 he reorganized the Harvard undergraduate body of about 3,200 students into seven separate, self-contained residential "Houses." He also originated and endowed the Society of Fellows, a selected group of younger research scholars, freed from conventional restrictions on graduate study. Author of several textbooks on European governmental systems, his influence on U.S. education is better typified by *Conflicts of Principle* (1932, rev. ed. 1956) and *At War with Academic Tradition in America* (1934), both illustrative of his lifelong concern for academic freedom. He died in Boston on Jan. 6, 1943.

LOWELL, AMY (1874–1925), U.S. poet, critic and lecturer, an exponent of the poetic doctrines of Imagism (q.v.), was born on Feb. 9, 1874, in Brookline, Mass., of a prominent and public-spirited family. She was educated by her mother and in private schools, afterward traveling widely abroad. At 28 she began to devote herself seriously to poetry, but published nothing until 1910, when a poem appeared in the *Atlantic Monthly*. Her first volume, *A Dome of Many-Coloured Glass* (1912), was succeeded by *Sword Blades and Poppy Seed* (1914), which included her first poems in *vers libre* and "polyphonic prose"; *Six French Poets* (1915); *Men, Women and Ghosts* (1916); *Tendencies in Modern American Poetry* (1917); *Can Grande's Castle* (1918); *Pictures of the Floating World* (1919), which reflected her new preoccupation with oriental poetry; *Legends* (1921); *Fire-Flower Tablets* (1921), with Florence Ayscough; *A Critical Fable* (1922); a biography of John Keats (1925); *What's o'Clock* (1925); *East Wind* (1926); and *Ballads for Sale* (1927). Throughout this period she wrote critical articles for periodicals and frequently lectured. After several years of illness, she died suddenly on May 14, 1925, at Brookline.

During her later years Miss Lowell was the most striking figure in American poetry. Her vivid and powerful personality, her independence and zest made her conspicuous, as did her scorn of convention in such defiant gestures as smoking cigars. Having been displaced by her as the leader of the Imagists, Ezra Pound promptly restyled them the "Amygists" in tribute to her dominating qualities. A bold experimenter in form and technique, she remained conservative at the core, retaining conventional verse forms and in her last years severing connections with all radical schools

of poetry. Characteristic qualities of her work include her mastery of the free verse technique, her brilliant use of sensuous impressions in depicting the external world, and the restrained beauty of many of her shorter poems.

BIBLIOGRAPHY.—Miss Lowell's complete poetical works appeared in 1955. For her own definitions of the principles of *vers libre* and "polyphonic prose" see the prefaces to *Sword Blades and Poppy Seed* and *Can Grande's Castle*, articles in *North American Review* (Jan. 1917) and *Dial* (Jan. 17, 1918). Biographies include W. Bryher, *Amy Lowell: A Critical Appreciation* (1918); R. Hunt and H. Snow, *Amy Lowell* (1921); S. F. Damon, *Amy Lowell: A Chronicle* (1935); Horace Gregory, *Amy Lowell: Portrait of the Poet in Her Time* (1958). For bibliography see Robert E. Spiller et al. (eds.), *Literary History of the United States*, 3rd ed. (1963).

LOWELL, JAMES RUSSELL (1819–1891), U.S. poet, critic and diplomat, who wrote extensively on a wide variety of subjects, but whose major significance probably lies in the interest in literature he helped develop through his writing, editing and teaching. Born in Cambridge, Mass., Feb. 22, 1819, he was the grandson of John Lowell and a member of the distinguished New England family which in the 20th century produced the poets Amy Lowell (q.v.) and Robert Lowell. His lifelong love of nature was nurtured by his rearing in the open countryside, and he had read avidly in Alexander Pope as well as in Spenser, Scott and the old ballads before he entered Harvard, where he followed his enthusiasms more than the instructions of the faculty. He graduated in 1838 and in 1840 took his degree in law, which helped fit him for his later diplomatic

THE GRANGER COLLECTION

LOWELL, DETAIL OF PHOTOGRAPH BY MATHEW BRADY

posts, although he did not care to practise law as a profession. His first period, up to about 1850, was dominated by humanitarian interests, notably abolition, in accord with the pressures of the era in New England. In 1844 he was married to the gifted poet Maria White, who was also an ardent humanitarian and who had helped inspire his poems in *A Year's Life* (1841). After a three-months' editorship (with Robert Carter) of the abortive periodical *The Pioneer* in 1843, attracting work by Hawthorne, Poe and Whittier, Lowell published the appreciative *Conversations on Some Old Poets* (1845), in which literary discussion did not exclude sentimental pleas for freeing the slave and for utopianism transcending nationalism. From 1845 to 1850 he wrote about 50 antislavery articles for such periodicals as the *Pennsylvania Freeman*, the *London Daily News* and the *National Anti-Slavery Standard*. Even more effective were his *Biglow Papers* which he began to serialize June 17, 1846 (the first series of which was collected in book form in 1848); written in New England dialect, these satirized the Mexican War as an attempt to extend the area of slavery. This "miraculous year" 1848 also saw the publication of the somewhat Tennysonian *Vision of Sir Launfal*, with its humanitarian theme that "the gift without the giver is bare," and the rollicking and witty *Fable for Critics*, urging American readers to "forget Europe wholly" in glorifying native humanitarian poets such as Whittier.

Lowell's second period, roughly from 1850 to 1867, shows him gradually turning from his earlier antitraditional humanitarianism to nationalism or Unionism, in response to new pressures of the time, notably secession. A trip to Italy and England (July 1851–Oct. 1852) made him less antitraditional, as "Leaves from My Italian Journal" (1854) suggests; and the death of three of his children, followed by the death of his beloved wife in 1853, gave him a taste of sorrows beyond the remedy of legislative reform. In 1855 his lectures on English poets before the Lowell institute led to his appointment as Smith professor of modern languages at Harvard, succeeding Longfellow; these lectures were richly ap-

preciative of the older poets but centred (as "The Function of the Poet") on the theme that America has ample resources to inspire great poetry. Again he went to Europe to study in Germany and Italy, returning in Aug. 1856 for his fruitful professorship of 20 years. In 1857 he married Frances Dunlap, who had cared for his only remaining child, Mabel; and in that year he began his four years' editorship of the new *Atlantic Monthly*, to which he attracted nearly all the major New England authors who (partly through association at the Saturday club) provided mutual stimulation and ushered in a golden day of American literature. As editor, Lowell encouraged them to find the ideal in the real, in the "simply natural" American scene and vernacular as he tried to illustrate in his second series of *Biglow Papers*, devoted to Unionism and collected from the periodicals in 1867. These include "Sunthin' in the Pastoral Line" which, along with "New England Two Centuries Ago" (1865), illustrates the way in which, in the face of the threat to the Union, he drew upon his native Puritan heritage of ordered liberty, which he contrasted to what seemed to him the program of anarchy involved in disunion. His central hope in this period was that "a strong nation begets strong citizens," that (as he says in the "Ode Recited at the Harvard Commemoration" of her dead) the mutable many might find worthy perpetuation in the immutable One, a coercive Union, which he glorified in essays such as "E Pluribus Unum." "Washers of the Shroud" (1862) had warned that the nation could be preserved only if Americans subordinated "the Many's plaudits" and "Opinion's Wind" to "Knowledge, Will," and especially to obedience to the divine "Law before all time." The "Commemoration Ode," glorifying "the pith and marrow of the nation," had included the moving tribute to the martyred Lincoln in whom there was "nothing of Europe"—Lincoln who was the product of "the unexhausted West" which was to interest Lowell increasingly as one of the chief nurseries of what he regarded as distinctive national traits—self-reliant individualism, equality and optimism.

Lowell's third period, from about 1867 to the end, was inspired by the growing proof, in the corruptions of the Grant administration, that the Union's having been preserved did not automatically beget morally strong citizens. He saw that he must now change emphasis again and centre his work on ways and means of making the individual man "sole sponsor of himself," on self-mastery in the midst of greed and perpetual temptation. One of the chief means Lowell used to help a new people, which he thought unduly optimistic and without steadying aids, was tradition, the examples of the heroes of the entire past, especially as embodied in literature. Thus, partly through his editorship (with C. E. Norton) of the *North American Review* (1864–72), Lowell published his successive critical essays on the great masters such as Dante, Chaucer, Spenser, Shakespeare, Cervantes, Calderón, Milton, Dryden, Pope, Fielding, Lessing, Gray, Wordsworth, Carlyle and Emerson. Guided by Edmund Burke's view of an organic tradition and by Coleridge (the "first of critics"), Lowell sought to winnow and sift ideas of the past which could fruitfully be brought to bear with all their "plastic force" on the needs of contemporary Americans. Thus he exalted the Greeks' "sense of proportion, their distaste for the exaggerated"; Dante's sense of free-willed responsibility in the face of the individual's inward conflict between appetite and aspiration; and Shakespeare's view that this conflict can be resolved not so much on the theological as on the sunlit human plane. Historical tradition ("clarified experience") teaches "the value of personal character as a chief factor in what used to be called destiny." In his long reflective poem, "The Cathedral," in which he spoke of God as being "so far above, yet in and of me," Lowell wistfully concluded that the supernatural faith of the middle ages is "irrecoverable," but he concluded that modern science, agnostic as it seems, can be made to accord with a modified religious faith, that the "cure-all equality" and the "brute's license of unfettered will" need the reinforcement of "private virtue strong in self-restraint." His "Three Memorial Odes" held that true freedom is the fruit of self-control guided by the human ideal synthesized by culture and a sense of the steadying power of tradition; these lofty "public" poems called for "symmetry of self-control," for self-discipline, for "making

man sole sponsor of himself," for "rounding a whole life to the circle fair of orb'd fulfillment." His achievement was rewarded by honorary degrees from Oxford (1873) and Cambridge (1874).

Lowell's literary cosmopolitanism was crowned by diplomatic responsibilities: Pres. Rutherford Hayes rewarded his support in the Republican convention in 1876 by appointing Lowell minister to Spain (1877–80) and ambassador to England (1880–85). Few diplomats have had Lowell's personal success in creating international good will and understanding. In England he served as president of the Wordsworth society, succeeding Matthew Arnold, with whom he is often compared in his idealism and many-sided social criticism; he was popular as a speaker on many notable cultural occasions, and as president of the Birmingham and Midland institute in 1884 he delivered his remarkably wise and persuasive discourse on "Democracy," centring on the elements common to the British and U.S. governmental traditions which he contrasted in the vein of Burke with the antitraditionalism of the French Revolution. His only difficulty during his responsibility in England was with a small number of Irishmen in English prisons (during the Fenian turmoil), who tried to get Lowell to intercede on the pretense that they had been U.S. citizens. In the change of administrations Pres. Grover Cleveland appointed a successor and Lowell returned home in June 1885, his wife having died in February. He made four more summer visits to England. He died in the house of his birth in Cambridge, Mass., on Aug. 12, 1891.

Lowell's tolerant defense in reviews of such realists as W. D. Howells and Henry James (who wrote two eulogistic essays on him), his long succession of critical disciples such as Barrett Wendell, George Woodberry and Edmund Clarence Stedman, not to mention writers devoted to the use of the racy vernacular, such as George Eggleston and J. C. Harris, attest to the vitality of his influence. Norman Foerster in 1928 concluded that in combining impressionism, historical understanding and judicial criticism, Lowell's literary creed "is the most representative of man's artistic experience through the ages yet attained in America."

BIBLIOGRAPHY.—The most comprehensive collection of his works is the Elmwood edition of *The Complete Writings of James Russell Lowell*, 16 vol. (1904), ed. by C. E. Norton, including the *Letters* (3 vol.); *Lowell: Representative Selections* (1947), ed. by H. H. Clark and N. Foerster, contains an extensive critically annotated bibliography of studies about Lowell, as well as a documented introduction of about 140 pages including Foerster's essay on his criticism. H. E. Scudder's *Lowell: A Biography* (1901) is supplemented by Leon Howard's *Victorian Knight-Errant* (1952), which covers the period up to 1855 and makes use of fresh manuscript material, and by R. C. Beatty's *James Russell Lowell* (1942), which reflects the southern attitude toward his political work. M. Duberman's *James Russell Lowell* (1966) is a reappraisal extolling Lowell's personal qualities above his merits as a poet. (H. H. CL.)

LOWELL, PERCIVAL (1855–1916), U.S. astronomer and founder of the Lowell observatory, was born in Boston, Mass., on March 13, 1855. A member of a brilliant family, he graduated with honours at Harvard in 1876 and after a year of travel returned to Boston where he was active in business. From 1883 to 1893 his energies were chiefly devoted to literature and travel, much of the time in the far east, which he pictured in *Choson* (1885), *The Soul of the Far East* (1888), *Noto* (1891) and *Occult Japan* (1895). During part of this period he was counselor and foreign secretary to the special mission from Korea to the U.S. In the 1890s, inspired by Schiaparelli's discovery of the "canals" on Mars, he determined to devote his fortune and energy to a study of the planets and after careful scrutiny of desirable sites founded the Lowell observatory at Flagstaff, Ariz.

Lowell held the theory that intelligent inhabitants of dying Mars are struggling to keep alive by a planet-wide system of irrigation from the water of the melting polar snowcaps and that the canals are bands of cultivated vegetation dependent on such irrigation. Among his books on this subject, *Mars and Its Canals* (1906) is a good example. Early in the 20th century he made an elaborate mathematical study of the perturbations of Uranus which he attributed to the action of an unseen planet beyond Neptune (*Memoir on a Trans-Neptunian Planet*, 1915); and in 1905 he organized a systematic search for such a planet by the staff of his observatory. Fourteen years after his death, this search

culminated successfully in the discovery of Pluto (1930). Although Lowell's Martian theory met with opposition, the value and sincerity of his work were recognized and he received numerous honours. Lowell died at Flagstaff, Nov. 12, 1916.

See L. Leonard, *Percival Lowell* (1921); J. A. Paterson, "Percival Lowell—His Life and Work," *Journ. Roy. Ast. Soc. Canada*, vol. 16, pp. 230 ff. (1922); A. Lawrence Lowell, *Biography of Percival Lowell* (1935). (J. C. DS.)

LOWELL, a city and one of two seats of Middlesex county (the other is Cambridge) in the northeast section of Massachusetts, U.S., 25 mi. N.W. of Boston and 7 mi. from the New Hampshire boundary, is on the Merrimack river at the mouth of the Concord river. It is a leading manufacturing city, one of the oldest in the United States. Pop. (1960) 92,107; standard metropolitan statistical area (Lowell city and six towns in Middlesex county) 164,243. (For comparative population figures see table in MASSACHUSETTS: Population.)

At the close of the 18th century there was only a small village at the juncture of the Merrimack and Concord rivers. A carding mill was built in 1801, and in 1804 the Middlesex canal was completed around Pawtucket falls, where the Merrimack drops 35 ft. Water power provided by these falls was an important factor in the city's location and industrial development. The town was incorporated in 1826 and was named for Francis Cabot Lowell, regarded as the originator of American cotton manufacturing. In 1836 the town was chartered as a city. A city-manager form of local government was adopted in 1944. The canal system, important in the growth of Lowell, comprises about 15½ mi. of waterways, parts of which run at right angles to the rivers and divide the city into sections. The waterways, along with a network of highways, compose an interrelated transportation system for industry and commerce.

In the 19th century large numbers of foreign workers were attracted by the textile industry which reached its peak in the early 1920s and decreased thereafter. Many mills had moved to the southern states by the 1950s, causing a decline in population. However, new industries began to replace textiles and Lowell's economy became more diversified.

About 200 ac. were set aside as an industrial park under the control of a commission, and new industries located there include electronics, plastics and light metals. Other manufacturing establishments produce a wide range of goods including chemicals, machine parts, electronic equipment, fabricated rubber, household tools, cloth and art supplies.

Lowell as an early 19th-century industrial city aroused the interest of Europeans and prompted many to journey across the Atlantic to visit and write of their impressions. Michel Chevreton, the French scholar, came in 1834. Two English observers, Charles Dickens and Anthony Trollope, followed a decade later. For a greater part of the 19th century Lowell was known as the "spindle city" and the "Manchester of America." Although best known for its pioneering textile industries, Lowell is also famous as the birthplace of the American artist, James Abbott McNeill Whistler, whose house has been converted into a museum. The city has provided two governors for Massachusetts—Benjamin F. Butler (1883–84), and Francis T. Greenhalge (1894–96).

Lowell has a state teachers college (1894); Lowell Technological institute (1895), which offers research facilities to local industry; a city hospital and two private hospitals; one of the largest libraries in New England; and a city memorial auditorium (1950) for community cultural and civic assemblies. (L. G. H.)

LOWER AUSTRIA: see AUSTRIA, LOWER.

LOWER CALIFORNIA: see CALIFORNIA, LOWER.

LOWER SAXONY (NIEDERSACHSEN), one of the *Länder* (states) of the Federal Republic of Germany, was established on Nov. 1, 1946, by merging the Prussian province of Hanover with the historical *Länder* of Brunswick, Oldenburg and Schaumburg-Lippe. Area 47,383 sq.km. (18,295 sq.mi.). Pop. (1961) 6,640,855. Lower Saxony extends eastward from the Netherlands border to the German Democratic Republic, bounded on the north by the North sea and the *Länder* of Bremen, Hamburg and Schleswig-Holstein and on the south by the *Länder* of North Rhine-Westphalia and Hesse.

Rhine-Westphalia and Hesse. The capital is Hanover.

The three main divisions are the large lowland of heath, bog and polders in the north; a narrow east-west zone of loess and loam (the *Börde*) farther south; and, in the south of the *Land*, a large portion of the Mittelgebirge or central uplands. The northern lowland is blanketed by glacial sands called *Geest*. The low-lying part, the *Moor* (swamp), with the water table near the surface, is covered with bogs of sphagnum grasses. The more elevated part, on better drained sands, is clothed with heather, juniper, scattered woods of oak and birch and pine plantations; its highest (330–500 ft.) and most characteristic area is the Lüneburger Heide (*q.v.*) between the Weser and lower Elbe rivers. The coastal belt of drained and diked polders (*Marschen*) is dominated by the great ports of Bremen and Hamburg (which form separate *Länder*) and by the lesser and more recent Emden and Wilhelmshaven.

The *Börde*, a belt of treeless arable land which includes the foothills of the Harz mountains, supports a dense farming population on its fertile soils. Rural and urban settlement is mostly on the border of the central uplands, where many small towns were established at the junction of land routes in medieval times.

Wide valleys lead southward through the central uplands between the Rhine plateau and the Thuringian highlands. This southern section includes the Weser uplands, which extend from the Teutoburger Wald eastward to the Harz mountains and are drained by the Weser and Leine rivers. These occupy wide fertile troughs between wooded hills and formed historic natural route-ways to Frankfurt am Main and southern Germany.

In the period 1939–56 the population of Lower Saxony increased by 43%, principally from the influx of more than 2,000,000 refugees and expellees. The population density exceeds 360 per square mile, the greatest concentration being in the *Börde*—notably in Hanover and Brunswick. The other chief towns are Emden, Wilhelmshaven and Cuxhaven on the coast; Oldenburg and Delmenhorst in the northern lowland, with Lüneburg and Celle, respectively, north and south of the Lüneburger Heide; Osnabrück, Hameln, Hildesheim, Wolfsburg, Salzgitter, Goslar and Göttingen in the *Börde* and central uplands. (See also articles on the various towns.)

The name Lower Saxony applies to a geographic cultural entity that took shape in the middle ages but had no political connotation until 1946. The nucleus is the 19th-century kingdom of Hanover, with its strong ties with England (*see* HANOVER). Administratively the state is divided into 8 districts (*Regierungsbezirke*), 60 rural districts (*Kreise*), 16 municipalities and 4,267 communes. It is governed within the framework of the federal constitution by a state diet of 159 members under a minister president. Institutes for higher education include the famous University of Göttingen with about 7,500 students, technical universities (*technische Hochschulen*) at Hanover and Brunswick, a veterinary college at Hanover, a college of social studies at Wilhelmshaven and a mining academy at Clausthal.

About 30% of the labour force works in agriculture or fishing, 36% in manufacturing and building, 15% in commerce and transport and 18% in private or public service.

The sparsely peopled northern lowland has a predominantly farming population on holdings seldom exceeding 50 ac. The northern marshland, diked and drained, is partly rich meadows and partly arable, producing good wheat crops. Dairy farming and the raising of beef cattle are important. Farm holdings of great antiquity are situated on the sandy *Geest* soils. The bogs were reclaimed after the 17th century by removing the peat or by burning the heather and grass and sowing buckwheat, or (later) by deep plowing to mix the peat with the underlying sands. The holdings are chiefly family ones producing rye, oats and potatoes and raising cattle and pigs. Pine plantations are numerous in the north; sheep raising and beekeeping are traditional.

The farmsteads of the *Börde* are clustered in large villages. Wheat and sugar beet are grown in rotation, and beef and dairy cattle are raised. Amid the Weser uplands, with their varied relief, are numerous lowlands on clay and loess, where wheat and sugar beet are grown.

Lower Saxony has important natural resources. Low-grade iron

ores are mined in the Salzgitter area and output is about one-third of the Federal Republic's production. There are iron and steel plants at Salzgitter and also at Peine, between Brunswick and Hanover. These plants use Ruhr coal brought by the Mittelland canal. Lignite is mined near Helmstedt, but most of the deposit lies east of the Democratic Republic's border. Petroleum is obtained near Celle and Peine and in the Emsland (*q.v.*) area between Bentheim and Papenburg; the *Land* is one of the chief European producers of crude oil amounting to about 5,000,000 tons annually.

Both Hanover and Brunswick have a diversity of manufacturing and processing industries. One of the largest automobile plants in Europe is at Wolfsburg, about 50 km. (31 mi.) N.E. of Brunswick. These industrial centres, together with the iron and steel plants, owe much to the Mittelland canal opened in the late 1930s.

(R. E. Dr.)

LOWESTOFT, a municipal borough, North sea port and resort town in the Lowestoft parliamentary division of Suffolk, Eng., is 44 mi. N.E. of Ipswich and 27 mi. S.E. of Norwich by road. Pop. (1961) 45,730. In 1086 Lowestoft was a hamlet in the demesne of the royal manor of Lothingland. A weekly market on Wednesdays was granted in 1308 to John, earl of Richmond, together with an eight days' fair. In 1442 William de la Pole, earl of Suffolk, received a further grant of the same market and also two yearly fairs. In 1643 Lowestoft supported the royalist cause but Cromwell carried off the chief supporters. For several centuries Lowestoft was in dispute with Yarmouth over the herring fisheries until the matter was finally settled in the house of lords in 1662. In 1665 the Dutch under Adm. Jacob Opdam were defeated off Lowestoft by the English fleet commanded by James, duke of York. Lowestoft china, of soft-paste porcelain, specializing in table and tea wares often bearing Chinese patterns, was made in the town from 1757 to 1802. The old town stands on a declivity (Lowestoft Ness, the most easterly point of Great Britain) to the north of the present harbour, which was constructed by the Norwich and Lowestoft Navigation company in 1831 and considerably extended by Samuel Morton Peto in 1846. Following the improvement of the harbour and the opening of the railway link with Norwich and London in 1847 Lowestoft developed rapidly as a port and coastal resort. The population increased from 4,671 in 1831 to 21,905 in 1885 when it was granted borough status. There are good sands as well as a fine esplanade and two piers; South pier has a pavilion. Oulton Broad within the borough boundary provides yachting, motorboating and a swimming pool. The parish church of St. Margaret dates from the 15th century.

The outer and inner harbours have quays for the important herring and trawl industry, and for general trade. On the south bank of the inner harbour six construction slips for vessels up to 300 ft. in length were added to the shipbuilding facilities of the port. Other industries include canning and food preservation, and the manufacture of television sets, marine radios, electrical apparatus, motor coaches and footwear.

LOWIE, ROBERT HARRY (1883–1957), U.S. anthropologist, a leading figure in the development of cultural anthropology, was born June 12, 1883, in Vienna, and was brought to New York at the age of ten. He graduated from the College of the City of New York at 18 and, while teaching elementary school for three years, studied under Franz Boas at Columbia university, where he received his Ph.D. in anthropology in 1908. From then until 1921 he was affiliated with the American Museum of Natural History in New York and undertook many of his major field trips to the Plains tribes, *inter alia* to the northern Shoshone, Assiniboin, Blackfoot and Crow. From 1921 to 1950 he was professor of anthropology at the University of California in Berkeley, serving as chairman of the department for 14 years. His honours and duties included: editorship of the *American Anthropologist* (1924–33); presidency of the American Folklore society (1916–17), the American Ethnological society (1920–21) and the American Anthropological association (1935); and election to the National Academy of Sciences (1931). Awards were the Viking medal (1947) and the Huxley medal (1948).

Lowie's most original ethnographic contributions are contained

in about 18 monographs on American Indians. Of these his studies on the Crow Indians engaged his most enduring interest and became classic. Later in life he turned to South American ethnography and then to the German culture in which he had been steeped in his youth. Although strongly empirical by conviction, he made distinguished theoretical contributions to the fields of kinship and social organization and folklore and religion. In his younger years he had a strong philosophical bent and wrote widely for liberal, intellectual journals. He died on Sept. 21, 1957, in Berkeley, Calif.

His outstanding books are *Culture and Ethnology* (1917), *Primitive Society* (1920), *Primitive Religion* (1924), *Origin of the State* (1927), *Crow Indians* (1935), *The History of Ethnological Theory* (1937), *Social Organization* (1948), *Toward Understanding Germany* (1954), and, published posthumously, *R. H. Lowie, Ethnologist: a Personal Record* (1959), and *Selected Papers in Anthropology* edited by Cora Du Bois (1960).

See P. Radin, "R. H. Lowie," *American Anthropologist*, vol. 60 (1958). (C. D. B.)

LOWIN, JOHN (1576–1653), English actor, the son of a carpenter and a colleague of Shakespeare, was baptized on Dec. 9, 1576. A goldsmith's apprentice for eight years, he joined Worcester's men as an actor in 1602. By 1603 he was a member of the King's company. He is known to have specialized in the roles of comic soldiers as well as downright villains. He created Bosola in Webster's *The Duchess of Malfi*. Shakespeare is said to have coached him in the part of Henry VIII. Lowin was also remembered for his Falstaff and the Jonsonian parts of Morose (*Epi-coene*), Volpone and Mammon (*The Alchemist*). After the death of John Heminge, Lowin became, with Joseph Taylor, co-manager of the King's company. As such he received payments for the company's appearances in court performances. He also acquired shares as a housekeeper in the Globe and Blackfriars theatres. At the outbreak of the English Civil War, after the theatres' closing, Lowin became an innkeeper at Brentford. He was buried on Aug. 24, 1653. (A. M. N.)

LOW SUNDAY, first Sunday after Easter. It is called in Latin *Dominica in albis* (*depositis*), "Sunday in white garments (laid aside)," in allusion to the fact that those who were baptized on Easter have put aside their white robes.

See also CHURCH YEAR.

LOW-TEMPERATURE PHYSICS (CRYOGENICS) is that branch of physics which is concerned with the measurement and the interpretation of natural phenomena at low temperatures. This definition cuts across the classification of physics according to the kind of system under investigation; e.g., one speaks of low-temperature nuclear physics, low-temperature solid state physics, etc.

Strictly speaking any measurement below room temperature falls into one of these categories, but it has become customary to restrict the term low-temperature physics (often called cryogenics, although this word more correctly refers to the production of low temperatures) to physical research carried out at temperatures at or below the boiling point of oxygen; i.e., at temperatures below about 90° K. All temperatures in this article will be given on the absolute scale in degrees Kelvin (° K.). The reader is reminded that on this scale the absolute zero of temperature is at 0° K., corresponding to -459.7° F., or -273.2° C. (See THERMOMETRY.)

Basic Phenomena.—The discovery of techniques for reaching and sustaining very low temperatures opened a new frontier in the study of matter.

Since heat is created by the random motion of molecules (see HEAT), the elimination of it involves bringing matter as close to a static and ordered condition as nature permits. In the close-to-absolute-zero state, the opportunity for new investigation is comparable to the one that was opened when the content of the bulb used in cathode-ray experiments was brought close to a perfect vacuum.

At extremely low temperatures, the electric, magnetic and thermal properties of most substances are found to be greatly altered. Among the phenomena sometimes encountered perhaps the most

striking are superfluidity and superconductivity. Some metals, when cooled below a characteristic critical temperature, are perfect conductors of electricity; a current induced in them will continue indefinitely without being maintained. Liquid helium, below a certain temperature, can flow without apparent viscosity through channels a few millionths of an inch in width.

Energy Levels and Order.—Some basic theories commonly accepted up to the turn of the 20th century were casualties of low-temperature physics. The most striking example is the classical law of P. L. Dulong and A. T. Petit, predicting that the specific heat of solids should remain constant at all temperatures. It is indeed reasonably constant at high temperatures. However, it decreases with lowering temperature and finally vanishes in the limit of the absolute zero of temperature. The article QUANTUM MECHANICS describes this more fully and discusses how first A. Einstein and subsequently P. J. W. Debye drew up quantum modes to explain this unexpected low-temperature behaviour.

These models form part of the modern view that the microscopic components of any physical system can have only certain discrete amounts of energy; i.e., they can occupy only certain definite energy levels. This means that at the absolute zero, where a system in such a theory contains the smallest possible amount of energy, its components should all either occupy the single lowest energy level available to them, or at least, if this is not permitted by the Pauli exclusion principle, they should occupy the fewest possible and lowest possible levels. In terms of quantum mechanics the degree of disorder of a system is related to the number of energy levels occupied by the system's components in excess of the allowed minimum. According to this, therefore, the absolute zero of temperature is the point at which a system achieves its state of highest order. This is equivalent to the statement of the third law of thermodynamics (*q.v.*) that the entropy of any system vanishes at absolute zero, since the entropy is a measure of the disorder of a system. The rise in temperature of a system above the absolute zero is equivalent to its gradual disordering as its microscopic components occupy an increasing number of energy levels above the lowest possible ones. The manner in which this occurs depends uniquely on the values of these energy levels which in turn are determined by the detailed nature and behaviour of the individual components of the system in question. Thus the importance of cryogenic research arises from the fact that experimental observation of the low-temperature characteristics of a system furnishes vital clues to its spectrum of energy levels and understanding of which forms part of a theoretical analysis of the system.

A system will become disordered when the thermal energy available to its components becomes comparable to the spacing between their energy levels. This thermal energy is equal to kT , where T is the absolute temperature and k , Boltzmann's constant, is about 10^{-4} electron volt (ev) per degree. The spacing between the levels, however, depends, as was just mentioned, on the characteristics of the system and will thus be different for different systems. Thus what is a low temperature for one system may be a high temperature for another; e.g., in the absence of an external magnetic field the spacing between the levels of a system of nuclear magnetic dipoles is of the order of 10^{-7} ev, that between the levels of a system of ionic magnetic dipoles at least 10^{-5} ev. As a result, the thermal energy available at about 0.01° K. (10^{-6} ev) is high enough to distribute nuclear dipoles almost equally among the available levels, but is barely sufficient to excite a few nuclear dipoles. This means that for the former system 0.01° K. is a high temperature, while for the latter it is a low one.

Experimental Details.—When it is desired to measure the properties of a substance at a certain temperature it is necessary to place this substance in good thermal contact with a reservoir at the desired temperature. The simplest and most convenient kind of reservoir is of course a bath of liquid, and indeed low-temperature measurements are carried out as much as possible by this means, using the liquefied form of one of the substances listed in Table I.

In liquefaction, the cooling of the gas to its boiling point occurs by two methods, used singly or in combination. After a gas has

been compressed isothermally, it can be cooled either by adiabatic expansion, in which the gas pushes against a piston while it is thermally isolated, or by Joule-Thomson (isenthalpic) expansion, in which the gas expands through a throttle valve into a low-pressure space. The volume of gas cooled a small amount by either of these processes then precools the next batch of incoming, compressed gas in a counterflow heat exchanger, so that the next expansion begins at a slightly lower temperature and cools a little further. This process is repeated until the boiling point is finally reached. A thermodynamic discussion of the two expansion processes can be found in THERMODYNAMICS; detailed descriptions of various liquefiers are given by J. G. Daunt and S. C. Collins in their contributions to vol. xiv of the *Encyclopedia of Physics* (see *Bibliography*).

For experimental purposes the liquid which has been obtained is transferred into a so-called Dewar vessel, a double-walled, silvered glass (or highly polished metal) flask, with an evacuated space between the walls, very similar except for size to the conventional Thermos bottle. Liquid air, oxygen, nitrogen and even hydrogen can be kept in such a vessel without further thermal protection for several hours; liquid helium has such a low specific

Hence the order of the system has been increased. If this process has occurred while the system was in thermal equilibrium with some external bath at a fixed temperature, this means thermodynamically that the entropy of the system has been decreased isothermally. As discussed in THERMODYNAMICS, a system can change its entropy only by absorbing or releasing an amount of heat. Thus if the system is now isolated from its surroundings so that it cannot absorb any heat, and the external variable is then returned to its original value, the spacing of the energy levels is again what it was in fig. 1(A), but the entropy or the degree of order is still that in fig. 1(B), since the entropy has not changed in the second part of the process. Hence the system has been returned to the original external conditions with a lower degree of disorder, which means that the temperature of the system has been decreased.

This two-step operation is basic to all physical cooling processes. For a system consisting of a given number of gas molecules, the external parameter affecting the spacing of the energy levels is the volume in which the system is contained. Isothermal compression of the gas lowers its entropy, and its subsequent expansion to its original volume under conditions such that its entropy remains constant will leave the gas at a lower temperature than the initial one. For a variety of reasons, it is often both more convenient and more efficient to expand a gas under conditions such that its entropy changes by a small amount during the second step, as in Joule-Thomson expansion. However, the final state of the gas is always one of lower entropy than its initial value. In general, any cooling process involves the change of some external variable, first one way and then back to its original value, in such

TABLE I.—The Substances Commonly Used as Liquid Baths in Low-Temperature Research

Substance	Boiling point (° K.)	Melting point (° K.)
Air	86	49
Nitrogen	78	63
Hydrogen	20	14
Helium	4.2	—

heat that it can be kept for any length of time only if the Dewar flask is in turn surrounded by a similar, larger flask containing liquid nitrogen or air.

If provisions are made to seal the flask containing the liquid hermetically; e.g., by means of a metal cap and neoprene O-ring gaskets, the pressure over the liquid can be reduced with large vacuum pumps, resulting in a decrease of the temperature of the liquid, down to the freezing point of all the substances listed in Table I except helium. Temperatures between the freezing point of one substance and the melting point of the next lower one can be obtained with apparatus in which the flow of heat in and out of the sample under investigation can be controlled and varied. Helium, as will be discussed in some detail in a later section of this article, does not freeze at all under any pressure less than about 25 atm., so that in principle the liquid could be pumped down to arbitrarily low temperatures. However, the vapour pressure of the liquid becomes so low at about 1° K. that this temperature represents approximately the lower limit which can be achieved by this means.

Thus it is seen that various liquids, under atmospheric or reduced pressure, provide readily available experimental temperatures down to about 1° K. Although the bulk of low-temperature research is being carried out in this range, we have mentioned that for certain systems 1° K. is actually a rather high temperature, so that it is a matter of considerable physical interest to cool them further. In order to understand how this can be done it is well to return to the considerations of the state of order of a system.

The Principle of Cooling.—Consider an arbitrary system in equilibrium at some temperature T such that the thermal energy is large enough to excite most of the system's components into energy levels above the ground state. The distribution of the components among the different energy levels depends on the product of two factors, one the exponent of the ratio of the energy of a level to kT , the other an increasing function of this energy. This means that the level at which the energy is most nearly equal to kT will be most heavily populated, with a gradually lessening number of components occupying the levels of higher and lower energy on either side, as illustrated in fig. 1(A). If now there exists some external variable, such as the volume or the magnetic field, by means of which the spacing of the energy levels can be varied, then a change of this variable such as to increase the spacing of the levels will result in a redistribution of the components of the systems among fewer levels, as shown in fig. 1(B).

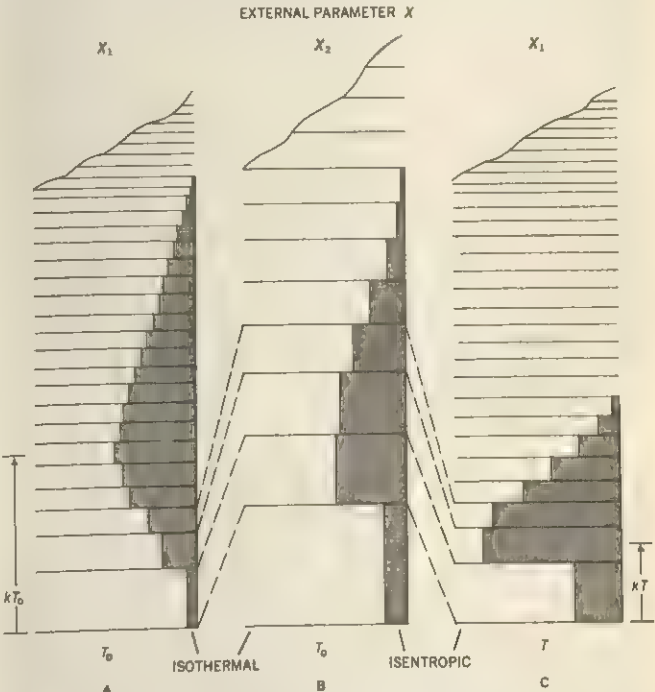

FIG. 1.—SCHEMATIC REPRESENTATION OF COOLING PROCESS. HORIZONTAL LINES REPRESENT VALUES OF ENERGY THAT COMPONENTS OF SYSTEM MAY HAVE. THE LOWEST LINE CORRESPONDING TO LOWEST ALLOWED ENERGY LEVELS. EXTERNAL PARAMETER X IS CHANGED FROM VALUE X_1 TO X_2 ISOTHERMALLY, AND BACK TO ORIGINAL VALUE X ISENTROPICALLY, REDUCING TEMPERATURE FROM T_0 TO T . VALUES OF CORRESPONDING THERMAL ENERGIES ARE SHOWN BY LENGTH OF VERTICAL ARROWS

a way that the spacing of the energy levels is first increased and then returned to its initial configuration. All this is done so that the final degree of order of the system is higher, which corresponds to a lower temperature.

Adiabatic Demagnetization.—In the case of the isothermal compression and adiabatic expansion of a gas, the ordering of the molecules is due to their taking up increasingly regular positions and to the fact that there is less room for movement. But the dis-

order of microscopic particles can be due not only to their random location, but also to varying orientation of certain directional quantities, such as the electric or magnetic dipoles which may be associated with the particles. Consider, for example, a crystal of a paramagnetic salt in which associated with each molecule there is a magnetic dipole. Although the spatial disorder of the molecules has to all intents and purposes disappeared at 1°K. , the orientation of the magnetic dipoles in the absence of an external magnetic field is still completely random. This is so because the spacing between the finite number of energy levels associated with the possible directions of the dipoles is so small compared with the thermal energy that all these levels are essentially equally populated. This situation, however, can be changed by applying an external magnetic field of 5–10,000 oersted, which will increase the spacing of the energy levels so much that most particles will occupy the lowest one. In terms of direction this simply means that the external magnetic field has aligned the majority of the magnetic dipoles parallel to itself. This corresponds to a high degree of order. If the salt is thermally isolated and the external field is then removed, the energy levels return to their original spacing without a change in the degree of order, which corresponds to a very low temperature for the system of dipoles. If good thermal contact exists between this and the salt as a whole, the salt will thus achieve a temperature which, depending on experimental details and the kind of paramagnetic salt used, can lie anywhere between 0.0015° and about 0.3°K. This method of cooling, called adiabatic demagnetization, was independently suggested by Debye and W. F. Giaque.

Limits of Low-Temperature Research.—We have seen that any cooling process requires two things: some system which at the initial temperature is still in a high degree of disorder, and some external variable by means of which the spacing of the energy levels of that system can be increased. At the lowest temperatures reached by adiabatic demagnetization of a paramagnetic salt with its system of ionic magnetic dipoles, there is still the system of nuclear magnetic dipoles which even at 0.01°K. are quite randomly oriented. Furthermore, this system is affected in the same manner as the ionic dipole system by the application of an external magnetic field, so that in principle the adiabatic demagnetization of a system of nuclear dipoles can be used to achieve much lower temperatures, estimated to be of the order of 0.00001°K. or even lower. In spite of considerable technical difficulties much progress is being made in this field, especially as nuclei whose magnetic dipoles are ordered in this fashion can be used for much fundamental research; e.g., research on the degree of symmetry of the physical universe.

Inevitably the question of even lower temperatures arises, and the answer is clearly that if at a temperature reached by nuclear demagnetization there is still some as yet unsuspected system with much disorder, i.e., high entropy, and in addition if this system can be ordered by means of some external variable, then even lower temperatures could be achieved. The reason for trying to achieve them would be to discover this as yet unknown system, as it is always true that much can be found out about a system from studies of that range of temperature in which it changes from great disorder to a high degree of order. If, on the other hand, there is no system which is still disordered at nuclear demagnetization temperatures, then not only would it be impossible to achieve lower temperatures, but it would be quite pointless to try, as nothing further could be found out about any system or set of systems once a perfect degree of order had been achieved.

The Measurement of Temperature.—The thermometers used at low temperatures are in principle the same as those used in any other range: they contain or consist of some substance of which one readily measurable parameter varies with temperature in a systematic and reproducible fashion. At room temperature such a device is the mercury thermometer, in which the length of the column of mercury varies linearly with temperature. Thermometers used at lower temperatures include the liquid bath itself, with its temperature-dependent vapour pressure; an amount of gas kept either at constant volume or at constant pressure; and thermocouples, electrical resistors or a paramagnetic salt. The

details of these devices, their accuracies and their limitations, are discussed in THERMOMETRY.

Each of these thermometers must of course initially be calibrated, which requires that for each range of temperature one must at one time or another determine the absolute temperature of some thermometric substance from first principles. Sometimes this can be done from a detailed understanding of the substance in question, from which one can then calculate the absolute temperature corresponding to any measured value of the temperature-dependent property. If such an understanding does not exist it is necessary to invoke the fundamental thermodynamic definition of temperature, namely, that it is the ratio of the amount of heat put into a system at that temperature to the resulting change in the entropy of the system, and to determine the temperature by measuring these changes.

AREAS OF LOW-TEMPERATURE RESEARCH

As was indicated in the introductory paragraphs of this article low-temperature physics includes theoretical and experimental research on all natural phenomena at temperatures below about 90°K. It therefore covers so many areas of investigation that it is impossible to give an adequate description of the entire field in this article. This is especially true as the relevance and importance of much low-temperature work can be understood only in terms of an over-all description of behaviour at all temperatures. The following, therefore, constitutes only a brief and inadequate summary of the principal areas of low-temperature physics. Technical but still general background information can be found in the reviews by D. K. C. MacDonald, P. G. Klemens, P. H. Keesom and J. van den Handel in the *Encyclopedia of Physics* (see Bibliography), and these articles in turn contain the references needed for a thorough study.

Low-Temperature Specific Heats.—The specific heat of any substance is, by definition, the temperature times the derivative of entropy with respect to the temperature. For a single system, therefore, the specific heat will be appreciable only in that region of temperature in which the entropy changes; i.e., in that range in which the system changes its degree of disorder. Most substances contain several such systems, and their specific heat is the sum of the specific heats of the individual systems. In order to separate the individual contributions it is necessary to extend specific-heat measurements to sufficiently low temperatures so that one or more of the systems reaches a state of order and thus an essentially vanishing specific heat. For example, the specific heat of a metallic conductor consists of two parts, one due to the metal lattice and one due to the conduction electrons. Although at normal temperatures the former is much larger than the latter, it becomes quite small at temperatures of the order of 10°K. This makes it possible to obtain the electronic specific heat of a metal.

Electronic Transport Phenomena.—In a metal at room temperature, the current- and heat-carrying motion of the electrons is impeded by the vibration of the lattice even in a perfect crystal. As is indicated by the decrease of the lattice specific heat, the spacing of the vibrational energy levels of the lattice is such that at temperatures of the order of 10°K. a considerable degree of order is attained. At such low temperatures, therefore, the scattering of the electrons by the lattice is much decreased, and both the electric and thermal resistivities are due mostly to the presence of lattice imperfections, impurities and strains. Low-temperature measurements of these resistivities make possible the separate evaluation of these various contributions, and have shown the great effect which crystal defects have on the characteristics of a metal and, for that matter, of any solid. Such investigations, together with specific-heat measurements, are among the most important in the continuing attempt to reach a satisfactory understanding of the solid state.

Magnetic Phenomena.—At various times in the preceding material we have spoken of systems of magnetic dipoles associated with microscopic particles. It is these which determine the magnetic behaviour of a substance. The low-temperature study of magnetism concentrates on two aspects of the characteristics of a

magnetic dipole system. There are, in the first place, extensive investigations in which the direction of these dipoles becomes ordered when the thermal energy becomes small compared to the spacing of their directional energy levels. This spacing, in the absence of any external fields, depends on the strength and the kind of interaction of these dipoles with the electric and magnetic fields created by the surrounding microscopic particles. The determination of the temperature at which the system changes from complete disorder (even distribution of the dipoles over all available levels) to some degree of order (preferential occupation of a few of these levels) thus yields information about the strength of these interactions. Depending on the kind of interaction there are different ways in which this directional ordering can occur. In addition to the kind of ordering of the dipoles into a single direction which gives rise to ferromagnetism and occurs at the temperature called the Curie point, after its discoverer, the dipoles can line up in more complicated patterns to give rise to antiferromagnetism, as predicted by L. Néel, or ferrimagnetism, as discovered by J. L. Snoek, E. J. W. Verwey and others.

It is, of course, also possible to change the degree of order of the magnetic dipoles by means of an externally applied magnetic field. Once this field is again removed the dipole system finds itself at a temperature different from that of the surrounding medium. It will then tend to return to the temperature of the surroundings by exchanging with the latter sufficient energy to re-establish a suitable degree of disorder. This process is called relaxation. The time necessary for complete relaxation clearly depends again on the interaction of the dipole system with its surrounding, and this interaction will in turn be affected by the degree of order of the various systems which make up the surrounding. Much useful information not only about the dipole system but also about the neighbouring systems can thus be obtained from a study of magnitude and the temperature dependence of these relaxation times.

In addition to the many areas of physical research in which the use of low temperatures forms only a part of a general investigation and analysis of a basic phenomenon, there exist two fields of study unique to cryogenics: the behaviour of liquid helium and the phenomenon of superconductivity. A detailed description of these two is, therefore, particularly germane to this article.

The Behaviour of Liquid Helium.—When H. Kamerlingh Onnes achieved the liquefaction of helium in 1908, he did not expect this element to have much intrinsic interest, and was mainly concerned with the extension of the experimentally available temperature range to lower values. It soon became apparent, however, that liquid helium was not only very useful to cool other substances, but had itself such unusual and unexpected properties as to warrant extensive and detailed investigation. In fact, these investigations, carried out for almost 20 years exclusively at Leiden, and later in cryogenic laboratories in many other countries,

uncovered behaviour so unlike that of any other substance that a full theoretical understanding is still lacking. This behaviour and its possible explanations will be discussed in terms of three aspects: the fluidity of helium under moderate pressures down to absolute zero; the existence of a phase transition to a second liquid phase; and the highly anomalous transport characteristics of this phase.

The Fluidity of Helium at 0° K.—Fig. 2 shows the phase diagram of helium, which is quite different from that of a normal substance. At atmospheric pressure the latter is in the gaseous phase at sufficiently high temperatures, condenses into a liquid upon cooling and finally freezes into a solid at some rather low temperature. This is, of course, to be expected from the concept of the relation between the temperature and the degree of disorder of a substance, from which one would conclude that with decreasing temperature, the molecules of a substance would acquire increasing order in space. The phase diagram of helium, however, shows that for pressures below about 25 atm. helium remains liquid down to the absolute zero. In fact, the horizontal melting-pressure curve shows, by application of the Clausius-Clapeyron equation (see THERMODYNAMICS), that at sufficiently low temperatures the entropy and therefore the degree of order of the liquid is the same as that of the solid phase.

Clearly this cannot be an order in space, which is precluded by the high mobility of the molecules even in a normal liquid. Instead there must occur, in liquid helium, an ordering of velocities, a possibility which follows from and is in this case actually dictated by the fundamental principles of quantum mechanics (*q.v.*). According to this modern view of the physical universe, the velocity and the position of any particle are of equal importance, and our instinctive emphasis on position is really only due to the fact that spatial ordering is more common and easier to visualize than ordering of velocities. The basic Heisenberg uncertainty principle of quantum mechanics goes one step further in stating that it is impossible to determine simultaneously the position and the velocity of a particle with arbitrary precision, and that the more accurately we measure the one, the more uncertain we become about the other. This means, therefore, that the close definition of the position of molecules upon freezing is accompanied by an uncertainty about their velocity; *i.e.*, the more narrowly a molecule is confined to a certain location, the greater the magnitude of the velocity with which it oscillates about this point. Another way of saying this is that any attempt to minimize the potential energy of a particle, by placing it in the most favourable position with respect to other bodies which either repel or attract it, is accompanied by an increase in the kinetic energy of the particle, which is the greater the more the particle is localized.

This means that at absolute zero a substance still has some potential and kinetic energy, adding up to what is called the zero-point energy. This is in sharp contrast to the classical view that at absolute zero a substance has lost all energy by having all its particles immobile in the position of minimum potential.

The increase in the particle's kinetic energy due to localization can easily be shown to be inversely proportional to the mass of the particle. With a helium atom, therefore, this energy is unusually large, while at the same time the weak forces existing between helium atoms render quite small the decrease in potential energy gained by having an atom in its most favourable position. It is thus energetically not favourable to localize the helium atoms, and thereby to create order in space; instead a lower total energy can be obtained by minimizing the kinetic energy, which is equivalent to reducing and hence ordering the velocity, at the cost of a small increase in potential energy.

The Phase Transition (λ point).—When liquid helium is cooled under its own vapour pressure, it undergoes a transition from one liquid phase into another at about 2.18° K. These phases are designated by Roman numerals, and one speaks, respectively, of liquid helium I and liquid helium II, the latter denoting the phase existing at lower temperatures. Several of the characteristic variables of the liquid undergo an abrupt change at this transition; in particular its specific heat has a discontinuity, as shown in fig. 3. The resemblance of the shape of this curve to a reversed

FIG. 2.—PHASE DIAGRAM OF HELIUM

Greek letter lambda has led to the designation of the transition point as the λ point. The dotted line in fig. 2 is called the λ line and indicates the different pressures and temperatures at which phases I and II are in equilibrium with one another. The highly unusual behaviour of liquid helium II will be discussed presently.

Certain features of the λ transition led F. London (1935) to suggest that it is a so-called order-disorder transition, similar to the Curie point of ferromagnetic substances. Between the normal boiling point and the λ point the ordering which occurs in liquid helium is much like that occurring in any liquid with decreasing temperature: the molecules are distributed over fewer and fewer of the energy levels corresponding to different velocities. At all these temperatures, however, the distribution is such that only an infinitesimal number of the molecules occupy the lowest or ground state. Below a certain quite sharply defined temperature, however, a finite number of the molecules are "condensed" into the ground state, corresponding to the lowest permitted velocities.

It is well to remember that this so-called zero-point velocity is not zero, since the partial localization of the atoms by the walls of the box in which they are contained precludes, according to the uncertainty principle, a vanishing and hence sharply defined velocity.

Below this transition, therefore, the liquid can be considered as consisting of two entirely intermixed components, one comprising all the atoms still distributed over the higher energy levels, and the other consisting of the atoms in the ground state. The former component is qualitatively similar to any liquid, and is therefore in this phenomenological view called the normal component.

The second component, however, should exhibit very astonishing features, since by inverting the uncertainty principle argument just used to show that the ground state velocity is finite, it is clear that the position of these atoms in the ground state is only defined by the walls containing the liquid as a whole. In a way, therefore, these ground-state atoms must be considered as being everywhere in the container at once, and hence should be able to move throughout the container without any friction. Because of this, this component is called the superfluid one. As the temperature decreases from the transition point an increasing number of atoms are condensed into the ground state and hence the superfluid component comprises an increasing fraction of the liquid as a whole, until at the absolute zero the entire liquid is superfluid.

London's phenomenological model of the λ transition received

FIG. 3.—THE SPECIFIC HEAT OF LIQUID HELIUM UNDER ITS VAPOUR PRESSURE AS A FUNCTION OF TEMPERATURE

much support with the discovery, isolation and investigation of a rare isotope of helium of mass 3. The condensation of many atoms into the ground state is possible only if these atoms follow Bose-Einstein statistics, and such a process is called Bose-Einstein condensation. The atoms of the prevalent isotope of helium, with mass 4, do follow such statistics, but the atoms of He^3 follow Fermi-Dirac statistics for which, according to the Pauli exclusion

principle, any energy level can only be occupied by a single particle. Thus, according to London, He^3 should not have a λ transition, although it too should remain liquid down to the absolute zero since the arguments for this fluidity are independent of statistics.

Indeed it has been found experimentally that down to the lowest temperatures at which it has been investigated (about 0.29° K.) He^3 does remain liquid but does not change into a superfluid phase.

At sufficiently low temperatures there begins to occur instead spontaneous alignment of the atomic magnetic dipoles.

These highly qualitative arguments of course do not constitute an explanation for the behaviour of liquid helium but at best indi-

cate a possible mechanism for the λ transition and the peculiarities of helium II. In particular it must be remembered that the division of this liquid into two components is highly artificial, as of course it is not possible to label any one atom as normal and some other as superfluid. The only distinction between them is that one carries a quantum of energy which the other does not. Any interaction between such atoms results in the transfer of this quantum from the one to the other, with a resulting exchange of identity with respect to being normal or superfluid. In fact a most fruitful systematic approach to a theory of liquid helium from first principles is that of L. Landau, who considers these freely interchangeable quanta of energy (generally called elementary excitations) separately as an independent system superimposed on a sea of particles all in the ground state.

The Characteristics of Helium II.—The principal features of liquid helium II are its ability to flow through narrow slits and capillaries without apparent viscosity, its almost unlimited thermal conductivity and its formation of thin films by means of which it flows over the rims of beakers, etc., to the lowest attainable level. Qualitatively, at least, the mechanism for most of these effects can be deduced from the two-component model described above. The nonviscous flow through narrow apertures is a consequence of the frictionless flow of the superfluid component. This also explains the film flow. The anomalously high ability to conduct heat arises from the fact that at any given temperature the liquid can be thought of as containing a certain fraction of superfluid which decreases with increasing temperature. If some heat is introduced into the liquid at one place, the fraction of superfluid there will decrease, with a corresponding increase in the number of normal atoms. Equilibrium will be re-established by an internal convection process in which superfluid atoms will travel toward the hot spot, and normal atoms away from it. As this counterflow occurs without viscosity due to the nature of the superfluid, it is all but impossible to establish a thermal gradient in liquid helium II. A spectacular demonstration of this is the fact that whereas liquid helium I in a Dewar vessel boils violently the liquid becomes completely quiescent as soon as the λ point is passed. This is because the boiling in a normal liquid is due to bubbles created at local hot spots, and these do not exist in liquid helium II. (See also PHASE EQUILIBRIA.)

Full descriptions and illustrations of the fascinating and often amusing behaviour of liquid helium II can be found in the first two books listed in the bibliography.

The Phenomenon of Superconductivity.—One of the first experimental uses to which Kamerlingh Onnes put his newly acquired liquid helium was the investigation of metallic conductors at low temperatures. While measuring the electric resistance of mercury he found, in 1911, that this variable at first decreased gradually with decreasing temperature, as expected, but that at about 4° K. the resistance fell very abruptly to a very low value. All attempts to measure this resistance failed, and he concluded that below this transition point mercury was what came to be called a superconductor with vanishing electric resistance.

Extensive experimental work since that time in many different laboratories has established that 22 metallic elements and a large number of intermetallic compounds become superconductive at temperatures ranging from about 17° K. down to about 0.1° K. The superconductive elements and their transition temperatures are listed in Table II. There is some reason to believe that at temperatures below 0.1° K. five more elements become superconducting, namely molybdenum, tungsten, ytterbium, scandium and protactinium.

While there is no room here for a detailed description of the characteristics of a superconductor, it is possible to discuss briefly the three major experimental discoveries which ultimately led to an understanding and theoretical analysis of the phenomenon.

Destruction of Superconductivity by a Magnetic Field.—A few years after the initial discovery of superconductivity, Kamerlingh Onnes and co-workers found out that the superconducting properties of a substance below its transition temperature could be destroyed by the application of an external magnetic field. Detailed investigation showed that this so-called threshold field in-

creased from a zero value at the transition temperature to a maximum at the absolute zero, varying in this range approximately

as the square of the difference between the transition temperature and the temperature of measurement.

It was realized several years later that this property made possible a thermodynamic treatment of superconductivity with the assumption that the transition from the normal to the superconductive state is reversible, but without any further knowledge of the details of the superconducting mechanism. If one considers the normal and the superconductive state of a metal as two phases which are in equilibrium at any point on the threshold magnetic-field curve, then the free energies of the two phases must be equal at any point on this curve. This makes it possible to relate the difference of the free energies of the two phases to the threshold field, and in turn allows one to express the difference in the entropies and the difference in the specific heats of the normal and superconductive phases in terms of the temperature derivatives of the threshold field, which can be experimentally determined. The relation for the entropy difference immediately shows that the superconductive entropy is less than the normal one at all finite temperatures below the transition, which means, as expected, that the degree of order of a superconductor is higher than that of the same metal in the normal phase. A further consequence, also experimentally verified, is that the specific heat shows a discontinuity at the transition.

The Meissner Effect.—The application of a simple thermodynamic treatment to superconductivity depends, as was mentioned, on the reversibility of the transition. This condition is not fulfilled for a perfect conductor, as indicated in the following example. Consider a potential superconductor at some temperature above the transition, and in an external magnetic field. When the temperature is lowered below the transition and the magnetic field removed, the sample will be superconductive, and if the transition is indeed reversible it should make no difference which of these steps is taken first. With a perfect conductor, however, it does matter: if the temperature is lowered in the presence of the field and the field is then removed, Faraday's law of induction, together with the ability of the substance to maintain currents without dissipation, requires that the magnetic induction inside the sample remain at the value which it had when the external field reached the threshold value. If, on the other hand, the field is first removed, and only then the temperature lowered, the magnetic induction inside the sample will be zero.

W. Meissner and R. Ochsenfeld showed in 1933 that in a superconductor the magnetic induction is zero regardless of the path along which the transition has occurred. They concluded that the vanishing of the magnetic induction inside a superconductor (called the Meissner effect) is a basic characteristic. It has, in fact, come to be considered more fundamental than the property of infinite conductivity.

The Meissner effect not only ensures the reversibility of the superconductive transition and thus allows the application of simple thermodynamic treatment, but has also enabled F. and H. London to draw up a set of very successful phenomenological equations governing the electromagnetic characteristics of superconductors.

The Isotope Effect.—Our understanding of superconductivity was further greatly increased when C. Reynolds, B. Serin and co-workers, and E. Maxwell discovered independently in 1950 that the superconductive transition temperature of an element depends

on its isotopic mass. As this mass is a property only of the metallic lattice, and the superconductive behaviour obviously involves the conduction electrons, this so-called isotope effect indicates beyond any doubt that the fundamental mechanism responsible for superconductivity involves the interaction between these electrons and the lattice. H. Fröhlich had suggested this possibility in 1950 on theoretical grounds without being aware of the concurrent experiments.

That this interaction should be responsible for superconductivity is in a sense quite remarkable, for it was mentioned earlier that it is just this interaction which in normal metals inhibits conductivity and is responsible for electrical resistance. However, J. Bardeen and co-workers in 1957 were able to show from first principles that under certain conditions and at sufficiently low temperatures this interaction affects the electronic energy levels in such a way as to make energetically favourable a type of condensation into low-lying levels with a resulting ordering of the velocities. The behaviour of these condensed electrons had previously been shown by Bardeen to lead to the basic superconductive characteristics, including the vanishing of the magnetic induction and the perfect conductivity.

BIBLIOGRAPHY.—The best nontechnical discussion of low-temperature physics is F. Simon *et al.*, *Low Temperature Physics* (1952). Best starting point for a more detailed study of the subjects mentioned in this article is vol. xiv and xv of the *Encyclopedia of Physics (Handbuch der Physik)*, ed. by S. Flügge (1956). These volumes contain articles in English on the production of low temperatures, low-temperature transport, thermal and magnetic properties of solids, superconductivity and liquid helium. Each of these articles in turn contains a full list of more detailed references. Of interest also is *Progress in Low Temperature Physics*, 3 vol., ed. by C. J. Gorter (1955–61) which contains up-to-date reviews of current research. See also J. G. Daunt *et al.* (eds.), *Low-Temperature Physics*, 2 vol. (1965); C. M. DeWitt *et al.* (eds.), *Low Temperature Physics* (1962); J. R. Dillinger (ed.), *Low Temperature Physics and Chemistry* (1958); L. Mackinnon, *Experimental Physics at Low Temperatures* (1965); K. Mendelsohn (ed.), *Progress in Cryogenics*, 4 vol. (1959–64); A. C. Rose-Innes, *Low Temperature Techniques* (1964); H. M. Rosenberg, *Low Temperature Solid State Physics: Some Selected Topics* (1963); M. Sittig and S. Kidd, *Cryogenics, Research and Applications* (1963); M. W. Zemansky, *Temperatures Very Low and Very High* (1964).

LOWTH, ROBERT (1710–1787), English bishop and student of Hebrew poetry, was born at Winchester on Nov. 27, 1710. He was educated at Winchester college, and New college, Oxford, and in 1741 was appointed professor of poetry at Oxford. Lowth was consecrated bishop of St. David's in 1766 and in the same year was translated to Oxford and in 1777 to London. He died at Fulham palace on Nov. 3, 1787.

Lowth's *Lectures on the Sacred Poetry of the Hebrews* (Eng. trans. from Latin, with notes, 1793), his chief work, had a great influence in England and on the continent. Their chief importance lay in the idea of looking at the sacred poetry as poetry, and examining it by the ordinary standards of literary criticism. He described the typical forms of Hebrew poetry as these occur in the Psalms. Lowth defined the principle of parallelism as the fundamental principle in Hebrew poetry, in contrast with the principle of metre which is fundamental in European poetry.

See P. Hall (ed.), *Sermons and Other Remains of Robert Lowth* (1834), with introductory memoir.

LOYALISTS (TORIES), AMERICAN, the names given to colonists who retained their allegiance to Great Britain during the American Revolution. Contemporaries bitterly called them "Tories" but their descendants in Canada and elsewhere and later generations of Americans have referred to them as "Loyalists." According to the most generally accepted estimate, about one third of the North American colonists were Loyalists. Scholars have tried to determine just what classes comprised the Loyalists but have not agreed on any precise classification. Loyalists were not confined to particular groups; they were in every section, every calling and every class of the thirteen colonies. In general, loyalism was strongest among officeholders and others who served the crown or proprietors; Anglican clergymen and their parishioners in the north; Quakers and other conscientious pacifists, such as members of German religious sects; large landholders, particularly in the north; and wealthy merchant groups in New

York city, Philadelphia, Baltimore, Charleston and elsewhere whose businesses and property were affected by the war. A considerable proportion of the professional and intellectual talent, mainly physicians, lawyers, teachers and writers, also opposed the revolutionary movements.

Motivations.—Colonial officeholders, usually men of eminence and power, had a vested interest in upholding the authority of the crown. Many had been born in England and lived in the colonies only because of their employment. Upon entering their positions, they had, moreover, taken special oaths of allegiance to the crown, oaths they considered binding. The Anglican clergy had likewise vowed allegiance and obedience to their king; many had been born in Britain, all had been ordained there, and large numbers received part of their incomes from England. Throughout the Revolutionary War most of them preached obedience and submission to authority and they undoubtedly influenced the political attitudes of their parishioners. This was not true in the south, however. There many of the most distinguished Patriots, or Whigs as they called themselves, were adherents of the established church and men chose sides with little reference to their church affiliation. Among Quakers many deplored the measures of the British government but as a matter of religious conviction abstained from violence and resistance and their leaders counseled obedience and respect for authority.

Among men of status and property who resisted change, detested the "vulgar mob," were appalled by the destruction of property and feared an uncertain future of independence, self-interest was the dominant motive in loyalism. But the most commonly shared trait among all Loyalists appeared to be an innate conservatism coupled with a deep devotion to the mother country and the crown. Numerous Loyalists at first urged moderation in the struggle for colonial rights; some sided with Great Britain slowly, others were driven into active loyalism by their radical fellow colonists who denounced as Tories all who would not join them. The Revolutionary War left no place for moderates or those who wished to remain neutral. More than any other single factor, apparently, the resort to violence by the radicals confirmed the conservatives in their position.

Loyalists were most numerous in the south, New York and Pennsylvania. New York, the most aristocratic of the colonies, was the Loyalist stronghold and contained more of them than any other colony. Two thirds of its land belonged to the Loyalists or the crown. New Jersey, Delaware, Maryland and Virginia had large Loyalist minorities. In North Carolina the Loyalists and Patriots were about equally divided. South Carolina and particularly Georgia contained Loyalist majorities. New England had fewer than any other section.

Loyalist War Efforts.—Even though Loyalists did not rise in a body in support of the British army, as British authorities had hoped they would, some joined the army and others organized guerrilla bands who, with Indian allies, terrorized the frontier from New York to Georgia. New York alone furnished about 23,000 Loyalist fighters, perhaps as many as all the other colonies combined. A few Loyalist units, such as Patrick Ferguson's "American Riflemen," Sir Banastre Tarleton's "Legion," Sir John Johnson's "Loyal Greens," and Walter Butler's "Tory Rangers," fought effectively. The Loyalist fighters aroused a vengeful hatred among the Patriots and when taken in battle were treated as traitors. George Washington detested them, saying as early as March 1776 that "they were even higher and more insulting in their opposition than the regulars." (Lorenzo Sabine, *A Historical Essay on the Loyalists of the American Revolution*, p. 14, The Walden Press, Springfield, Mass., 1957.) When Gen. Charles Cornwallis surrendered at Yorktown, Va., in 1781, Washington would grant no terms to the Loyalists who had fought against him, saying they were guilty of treason and deserved its penalties.

Congress recommended repressive measures against the Loyalists and all states passed severe laws against them, usually forbidding them to hold office, disenfranchising them and confiscating their property or taxing it heavily. Practically every state struck at them with a test act requiring citizens to renounce allegiance to George III and to promise to support the state against the

crown. Some Patriots took the position that, as George M. Wrong wrote in *Canada and the American Revolution* (1935), "a Tory is a thing whose head is in England and its body in America and its neck ought to be stretched." Almost everywhere the Loyalists suffered persecution. Beginning in March 1776 when Sir William Howe evacuated Boston for a safer base at Halifax, Nova Scotia, with about 1,000 Loyalists, approximately 100,000 Loyalists fled into exile. (This was between 3% and 4% of the total number of settlers in the colonies, estimated at 2,500,000–3,000,000 during the Revolutionary period.) The majority of those who fled (numbered at perhaps 37,000) ultimately went to Canada, where they and their descendants became known as "United Empire Loyalists." The remainder spread to the Bahamas, the West Indies, Florida and England.

Postwar Settlements.—The peace treaty of 1783 brought the Loyalists little comfort, even though it provided that congress would "earnestly recommend" to the states the restitution of Loyalist property and that there should be no further prosecutions of Loyalists or confiscations of their estates. Americans greeted those terms with flurries of protest and state legislatures refused to heed the recommendations of congress. In the first two years after the peace, returning Loyalists were sometimes tarred and feathered, mobbed and even hanged. Finally, by the beginning of the new government under the federal constitution in 1789, many regained their estates, but the confiscation laws were not repealed by the states, and in fact all the laws against the Loyalists were not erased until after the War of 1812. The British, meantime, had used the continued mistreatment of the Loyalists as one excuse for retaining certain military posts on American territory in the old northwest until 1796 in violation of the peace treaty.

Beginning during the war, the British government tried to care for exiled Loyalists by giving them lucrative positions, food, clothing, shelter and new homes in Canada and by compensating them for losses in property and income. At the end of the war, Loyalist officers received pensions at half pay and grants of land according to rank. In July 1783 parliament appointed commissioners, numbering ultimately five, to investigate Loyalist claims and establish schedules for compensation. As late as 1792 the British government was still meeting claims by grants of land. In all, it expended about \$30,000,000 in behalf of the Loyalists. See also references under "Loyalists (Tories), American" in the Index.

BIBLIOGRAPHY.—L. W. Labaree, "The Nature of American Loyalism," *Proceedings of the American Antiquarian Society*, liv, 15–58 (1943); an analysis of the causes of loyalism; C. H. Van Tyne, *The Loyalists in the American Revolution* (1902), the standard work; L. Sabine, *Biographical Sketches of Loyalists of the American Revolution* (1864); G. M. Wrong, *Canada and the American Revolution* (1935); L. Einstein, *Divided Loyalties* (1933); A. G. Bradley, *The United Empire Loyalists* (1932).

LOYALTY, as a general term, signifies a person's devotion or sentiment of attachment to a particular object, which may be another person or group of persons, an ideal, a duty or a cause. It expresses itself in both thought and action and strives for the identification of the interests of the loyal person with those of the object. Loyalty turns into fanaticism when it becomes without the object. Loyalty turns into resignation when it displays the characteristics of reluctant acceptance. A man without loyalty does not exist. It stirs and arouses him, brings meaning, direction and purpose into his life and unifies his activities. At the same time, loyalty has a social function. Only by man's willingness in co-operation with others, to invest his intellectual and moral resources generously and wholeheartedly in something beyond his own narrow circle has it been possible for communities of various kinds to emerge and continue to exist; among them family, church and nation. Both man and community are unthinkable without loyalty.

Political loyalty is devotion to, and identification with, a political cause or a political community, its institutions, basic laws, major political ideas and general policy objectives. A cause in which persons are loyal is often considered "lost" by those who do not share the loyalty; in the face of what seemed to other fearful odds, the Irish, Poles and Zionists never wavered in their

loyalty to the cause of their national independence, which they ultimately regained. Loyalty to the laws of Athens, which brought him into the world and nurtured and educated him, was the chief motive of Socrates in accepting death at the hands of a regime that he had opposed and ridiculed, rather than fleeing from prison when given the chance to do so.

The nature and content of political loyalty has varied greatly through the ages. In Greek political thought the principle of unity in life tended to preclude the possibility that a variety of important loyalties might lay claim to the individual and alienate him from the polis, the city-state. Aristotle's famous dictum that man is by nature a political animal stated well the conviction that man could realize his aspirations only by active participation in the affairs of the city-state, which was the highest of all communities because it aimed at a more comprehensive good than any other, and at the highest good, the perfection of human development. A man was expected to be loyal to the city-state and no one else.

Occasionally, however, a conflict of loyalties did arise. Loyalty to the vague concept of a Greek commonwealth of nations, standing over and above individual city-states and overriding local loyalties, inspired Athens' rejection of an alliance with Persia. In Sophocles' *Antigone* the heroine counters the ruler's decree forbidding the burial of her brother with a moving appeal to the moral law of Zeus, which, she believes, has more valid claims to her loyalty than the duly constituted government. Plato's *Republic* expressed concern that the enjoyment of family life and private property by the governing guardian class would result in a conflict of loyalties from which the state would emerge second best.

Other people in antiquity also searched for unity through the state. The Romans, extolling the virtue of political duty, proudly professed their loyalty in the saying *civis Romanus sum*, "I am a Roman citizen." In the Hebrew theocratic state, ruled by the agents of Yahweh, the essence of life consisted in serving and preserving the state, which was equivalent with obedience to God.

Christianity rejected the classical principle of unity in life through the state. While the state, as a divine institution, exercised powers originating with God and was therefore entitled to loyalty as long as it functioned within its natural limits, man could never hope to fulfill his spiritual destiny within the framework of a political organization. To achieve this end, man had to turn elsewhere. The dualism of loyalty postulated by Christianity is affirmed in Jesus' famous dictum, "Render unto Caesar the things that are Caesar's and unto God the things that are God's." Man was, as St. Augustine put it, a citizen of two cities, the city of man and the city of God. Political theorists have often given support to this concept of dual loyalty by defending, for example, the right to resist arbitrary or tyrannical governments, especially if the right is claimed in consequence of one's loyalty to God and the moral law. The Nürnberg and Adolf Eichmann trials have shown that absolute loyalty to the state may be demanded only if the state is guided by principles of right and justice.

The efforts of the rulers of the slowly emerging nation-states to enlist nationwide loyalties took place within the framework of feudalism. On the continent of Europe the result was often disappointing. In France, for example, vassals would owe loyalty only to their immediate lords rather than to the king; the latter, therefore, had no direct contact with the lesser vassals, who even retained the right to make war against him.

In England William I, determined to be a true sovereign rather than one feudal lord among many, imposed an oath upon all the important landowners. In 1086 at Salisbury they swore that they would be faithful to him against all other men. This oath, repeated under later monarchs and extended to all people, even the peasants, by Henry II (1176), was a "national act of homage and allegiance."

Allegiance, later defined by Sir William Blackstone as "the tie or ligamen, which binds the subject to the King, in return for that protection which the King affords the subject," has become a powerful legal weapon in the hands of governments, especially

those of English-speaking peoples, to promote loyalty and to punish disloyalty. Allegiance assisted the integration of the Norman "foreigners" with the English natives; formed the basis of British nationality; played a part in transforming the British empire into the Commonwealth of Nations, a result foreshadowed by the Balfour report of the 1926 imperial conference, according to which Britain and the self-governing dominions were "united by a common allegiance to the Crown"; and has been crucial in the definition of treason, which is a breach of the allegiance owed to the king in person.

In deference to the commonwealth countries, allegiance lost some of its legal significance; under the British Nationality act of 1948 a British subject is a commonwealth citizen. "Allegiance is no longer a source of British nationality but it may be a consequence of it" (O. H. Phillips, *The Constitutional Law of Great Britain and the Commonwealth*, p. 473 [1957]); and since 1949, nations also qualify for membership in the commonwealth when they accept the monarch "as the symbol of the free association of its independent member nations and as such as the Head of the Commonwealth."

Under the influence of nationalism Englishmen developed a second loyalty, one to the kingdom itself as distinguished from allegiance to the king as a person. On occasion, such as in 1399, 1689 and 1936, the conflict between the old allegiance and the new loyalty resulted in the victory of the latter over the former and the king's deposition or abdication. Thus, the new loyalty was certainly an important political factor. Yet, the law, refusing to take comprehensive cognizance of changes affecting the sovereign, continued to recognize allegiance to him rather than the newly discovered loyalty to his realm. Thus, treason has technically never ceased to be a crime against the king, although actually the state rather than the sovereign himself has been involved.

However, in Britain, as elsewhere, prosecution for treason is only one of the weapons to combat disloyalty. Especially in the era of fascist and communist world-wide conspiracies, loyalty investigations have been considered necessary for survival by executive departments and legislatures, in the United States notably by the house un-American activities committee and the internal security subcommittee of the senate judiciary committee.

Penal laws directed against disloyal individuals imperiling security include those dealing with espionage, sabotage, sedition, the advocacy of the overthrow of the government by force and violence (United States Smith act, 1940), and trading with the enemy.

Among measures designed to prevent disloyalty of individuals are oaths of allegiance for such purposes as naturalization and holding public office; detention, as provided by the British Emergency Powers Defence act (1939) and Regulation 18B issued thereunder and by the United States Internal Security act (1950); the denial of passports; and deportation of aliens.

Disloyal organizations are outlawed either by legislation, such as the United States Communist Control act (1954), which keeps the Communist party off the election ballots, or by judicial determination, such as the decision of the German federal constitutional court, which in 1956 declared the Communist party unconstitutional. At times, prohibitive legislation is restricted to reprehensible practices rather than outlawing the organizations themselves; this approach is found in Britain's Public Order act (1936), which makes it an offense to wear publicly uniforms signifying association with political parties.

President Truman's loyalty program (1947) was intended to afford the United States maximum protection against infiltration of disloyal government employees and to protect loyal employees from unfounded accusations. As the standard for the refusal of, or removal from, employment, the existence of reasonable grounds for believing that a person was disloyal was changed in 1951 to reasonable doubt concerning his loyalty. To administer the program, a loyalty review board heard appeals from loyalty boards established in each department. President Eisenhower's program (1953) substituted security for loyalty as the new standard. No person should be employed unless such employment was clearly

consistent with the interests of national security. All loyalty boards were abolished, with the head of an agency making the final decision in each case.

Both the U.S. programs, including loyalty oaths, and their counterparts abroad have been criticized on the ground that they deny basic individual rights. Defending the Canadian system, Prime Minister Louis Stephen St. Laurent asserted in a personnel security case in 1951 that the sole question was whether a certain person could or could not be trusted with secret defense material. "Assessment of character may be the only consideration in some instances. That is not a matter of charge, or trial or of proof. It is a matter of judgment."

Similarly, in 1956 a British conference of privy councilors stated that, while some of the measures that the state was driven to take to protect its security were distasteful and alien to tradition, it was right to continue the practice of tilting the balance in favour of greater security for the state rather than in the direction of safeguarding the rights of individuals.

In the effort to secure loyalty, totalitarian systems have accepted Rousseau's recommendations that there should be no independent associations within the state because they are formed at its expense.

By contrast, in democracies a wide variety of such groups is not only tolerated but encouraged because they all, subversives excepted, contribute to the formation of national loyalty—as illustrated by the British party out of power, called "her majesty's loyal opposition." Loyalties to nonnational groups, such as Jehovah's Witnesses, may even be permitted to take precedence over the highest symbol of national loyalty, as evidenced by the U.S. supreme court's opposition to compulsory flag salutes in public schools.

Those who, like the historian Arnold Toynbee, take a dim view of nationalism believe that national loyalties must be ultimately transferred to mankind as a whole. Only then will it be possible to realize not necessarily a new international organization but what the American philosopher Josiah Royce called "the hope of the great community." See also TREASON AND SEDITION.

LOYALTY ISLANDS (ÎLES LOYAUTÉ), a group in the South Pacific ocean belonging to France, about 60 mi. E. of New Caledonia, with a total land area of about 755 sq.mi. Pop. (1956)

10,946. There are three large islands, Uvéa or Uea (the northernmost), Lifu (Lifou) the largest island, with an area of 650 sq.mi. Maré or Nengone, and several small islands. They are coral islands of comparatively recent elevation, and in no place rise more than 250 ft. above sea level.

The Loyalty Islanders are Melanesians; the islands have separate languages, and in Uvéa one tribe uses a Samoan and another a New Hebridean form of speech. The Loyalty group was discovered at the beginning of the 19th century, and Dumont d'Urville laid down the several islands in his chart. Christianity was introduced into Maré by native teachers from Rarotonga and Samoa. Enough of the rocky surface is covered with a thin coating of soil to enable the natives to grow yams, taro and bananas. Fresh water, rising and falling with the tide, is found in caverns in Lifu, and by sinking to sea level a supply may be obtained in any part of the island. Coconuts are the chief product; copra and rubber the chief exports. The Loyalty Islands are political dependencies of New Caledonia.

See PACIFIC ISLANDS: *Administrative Groupings*.

LO-YANG, an ancient city in the lower valley of the Lo Ho, a right bank tributary of the Yellow river, in northern Honan province, China. Pop. (1958 est.) 500,000. Possibly the first true city at the site was built in the 11th century B.C., about 10 mi. E. of the present city. This served as the eastern capital of the Chou dynasty until about 770 B.C., when it became the chief capital, remaining so until 255 B.C. It was the eastern Han dynasty capital from 25 to 221 A.D. The Tu'pa (Toba) removed their capital southward to Lo-yang at the end of the 5th century, and Su rulers resided there at intervals, during the 6th century. Lo-yang was a Buddhist centre during the 6th and 7th centuries. After the 10th century the city declined to a position as a local administrative and trade centre. Thus Lo-yang occupies an important historical niche in Chinese culture and, because of its many ruins, tombs and walls, was for centuries one of the historic tourist centres of China. It was called Honanfu until 1913.

In 1955 a tractor factory was constructed amid the tombs and ruins on the western outskirts of the city. A new steam electric plant and mining machinery plants followed. Hard coal deposits near the city were mined. Cotton, wheat and other staple crops are grown and processed in this region, and the city regained importance as a regional trade centre. Since Lo-yang is on the east-west Lunghai railway, with north-south connections close by, its location is favourable to development. (J. E. SE.)

LOYOLA, SAINT IGNATIUS OF (ÍÑIGO LÓPEZ DE LOYOLA) (1491-1556), founder of the Society of Jesus, was born in the ancestral castle of the Loyolas in the Basque province of Guipúzcoa, Sp., in 1491. His life falls into four periods. The first (1491-1521) covers the years when secular ideals dominated him; the second (1521-24) is the critical period of reorientation; the third (1524-38) comprises the years of his belated studies; and the fourth (1539-56) those during which he founded and governed the Society of Jesus.

Ignatius, the youngest son in a noble and wealthy family, became in 1506 a page in the service of a relative, Juan Velázquez de Cuéllar, treasurer of the kingdom of Castile. In 1517 Ignatius passed as a knight into the service of another relative, Antonio Manrique de Lara, duke of Nájera and viceroy of Navarre, who employed him in military undertakings and on a diplomatic mission. While defending the citadel of Pamplona against the French, Ignatius was hit by a cannonball on May 20, 1521, sustaining a bad fracture of his right leg and damage to his left. This ended the first period, during which he was, on his own admission, "a man given to the vanities of the world, whose chief delight consisted in martial exercises, with a great and vain desire to win renown" (*Autobiography*, 1). Although his morals were far from stainless, Ignatius was in his early years a proud rather than sensual man. He stood just under five feet two inches in height and had in his youth an abundance of hair of a reddish tint. He delighted in music, especially sacred hymns.

The second period of Ignatius' life is perhaps the best known. After treatment at Pamplona, he was transported to Loyola on June 1521. There his condition became so serious that for a time

his life was despaired of. When out of danger, he chose to undergo painful surgery to correct blunders made when the bone was first set. The result was a convalescence of many weeks during which he read a life of Christ and a book on the lives of the saints, the only reading matter the castle afforded. He also passed time in recalling tales of martial valour and in thinking of a great lady whom he admired. In the early stages of this enforced reading his attention was centred on the saints. The anonymous version of the lives of the saints he was reading contained prologues to the various lives by a Cistercian monk who conceived the service of God as a holy chivalry. This view of life profoundly moved and attracted Ignatius. After much reflection, he resolved to imitate the holy austerities of the saints in order to do penance for his sins.

In Feb. 1522 Ignatius bade farewell to his family and went to Montserrat, a place of pilgrimage in northeastern Spain. He spent three days in confessing the sins of his whole life, hung his sword and dagger as symbols of his abandoned ambitions near the statue of the Virgin Mary, and, clothed in sackcloth, spent the night of March 24 in prayer. The next day he went to Manresa, a town 30 mi. from Barcelona, to pass the decisive months of his career, from March 25, 1522, to mid-Feb. 1523. He lived as a beggar, ate and drank sparingly, scourged himself and for a time neither combed nor trimmed his hair and did not cut his nails. Daily he attended Mass and spent seven hours in prayer, often in a cave outside Manresa.

The sojourn at Manresa was marked by spiritual trials as well as by joy and interior light. While sitting one day on the banks of Cardener river, "the eyes of his understanding began to open and, without seeing any vision, he understood and knew many things, as well spiritual things as things of the faith" (*Autobiography*, 30). At Manresa Ignatius sketched the fundamentals of his little book *The Spiritual Exercises*. Until the close of his studies at Paris (1535) he made some additions to it. Thereafter there were only minor changes until Pope Paul III approved it in 1548. *The Spiritual Exercises* is a manual of spiritual arms, containing a vital and dynamic system of spirituality. During his lifetime Ignatius used it to give spiritual retreats to others, especially to his followers. The booklet is indeed an adaptation of the Gospels for such retreats.

The remainder of the decisive period was devoted to a pilgrimage to Jerusalem. Ignatius left Barcelona in March 1523 and traveling by way of Rome, Venice and Cyprus, reached Jerusalem on Sept. 4. He would have liked to settle permanently there, but the Franciscan custodians of the shrines of the Latin church would not listen to this plan. After visiting Bethany, the Mount of Olives, Bethlehem, the Jordan and Mount of Temptation, Ignatius left Palestine on Oct. 3 and, passing through Cyprus and Venice, reached Barcelona in March 1524.

"After the pilgrim had learned that it was God's will that he should not stay in Jerusalem, he pondered in his heart what he should do and finally decided to study for a time in order to be able to help souls" (*Autobiography*, 50). So Ignatius, who in his *Autobiography* refers to himself as the "pilgrim," describes his decision to acquire as good an education as the circumstances permitted. He probably could have reached the priesthood in a few years. He chose to defer this goal for more than 12 years and to undergo the drudgery of the classroom at an age when most men have long since finished their training. Perhaps his military career had taught him the value of careful preparation. At any rate he was convinced that a well-trained man would accomplish in a short time what one without training would never accomplish.

Ignatius studied at Barcelona for nearly two years. In 1526 he was transferred to Alcalá. By this time he had followers, and the little group assumed a distinctive garb. Ignatius fell under suspicion of heresy, was imprisoned and tried. Although found innocent, he left Alcalá for Salamanca. There not only was he imprisoned but his companions were also apprehended. Again he won acquittal but was forbidden to teach until he had finished his studies. This prohibition induced Ignatius to leave his disciples and Spain.

He arrived in Paris on Feb. 2, 1528, and remained there as a

student until 1535. He lived on alms and in 1528 and 1529 went to Flanders to beg from Spanish merchants. In 1530 he went to England for the same purpose. In Paris Ignatius soon had another group of disciples whose manner of living caused such a stir that he had to explain himself to the religious authorities. This episode finally convinced him that he must abstain from public religious endeavour until he reached the priesthood.

During his long stay in the French capital, Ignatius won the coveted M.A. of the famous university. He also gathered the companions who were to be cofounders with him of the Society of Jesus, among them Francis Xavier (*q.v.*), Peter Favre, Diego Laínez (*q.v.*) and Alphonsus Salmerón. On Aug. 15, 1534, he led the little band to nearby Montmartre, where they bound themselves by vows of poverty, chastity and obedience, though as yet without the express purpose of founding a religious order.

Early in 1535, before the completion of his theological studies, Ignatius left Paris for reasons of health. He spent more than six months in Spain and then went to Bologna and Venice where he studied privately. On Jan. 8, 1537, his Parisian companions joined him in Venice. All were eager to make the pilgrimage to Jerusalem, but war between Venice and the Turkish empire rendered this impossible. Ignatius and most of his companions were ordained on June 24, 1537. There followed 18 months during which they acquired experience in the ministry while also devoting much time to prayer. During these months, although he did not as yet say Mass, Ignatius had one of the decisive experiences of his life. He related to his companions that on a certain day while in prayer he seemed to see Christ with the cross on his shoulder and beside him the Eternal Father, who said, "I wish you to take this man for your servant," and Jesus took him and said, "My will is that you should serve us." On Christmas day 1538 Ignatius said his first Mass at the Church of St. Mary Major in Rome. This ends the third period of his life, that of his studies, which were far from a formality. Diego Laínez, a clever man, judged that despite handicaps Ignatius had as great diligence as any of his fellow students. He certainly became in the difficult field of ascetical and mystical theology one of the surest of Catholic guides.

The final period of Loyola's life was spent in Rome or its vicinity. In 1539 the companions decided to form a permanent union, adding a vow of obedience to a superior elected by themselves to the vows of poverty, chastity and obedience to the Roman pontiff which they had already taken. In 1540 Pope Paul III approved the plan of the new order. Loyola was the choice of his companions for the office of general.

The Society of Jesus developed rapidly under his hand. When he died there were about 1,000 Jesuits divided into 12 administrative units, called provinces. Three of these were in Italy, a like number in Spain, two in Germany, one in France, one in Portugal and two overseas in India and Brazil. Loyola was, in his last years, much occupied with Germany and India, to which he sent his famous followers Peter Canisius (*q.v.*) and Francis Xavier. He also dispatched missionaries to the Congo and to Ethiopia. In 1546 he secretly received into the society Francis Borgia (*q.v.*), duke of Gandía and viceroy of Catalonia. When knowledge of this became public four years later it created a sensation. Borgia organized the Spanish provinces of the order and became third general.

Loyola left his mark on Rome. He founded the Roman college, embryo of the Gregorian university, and the Germanicum, a seminary for German candidates for the priesthood. He also established a home for fallen women and one for converted Jews.

Although at first Loyola had been somewhat opposed to fixing his companions in colleges as educators of youth, he came in the course of time to recognize the value of the educational apostolate and in his last years was busily engaged in laying the foundations of the system of schools which was to stamp his order as largely a teaching order.

Probably the most important work of his later years was the composition of the *Constitutions* of the Society of Jesus. In them he decreed that his followers were to abandon some of the traditional forms of the religious life, such as chanting the divine office,

corporal penances of rule and penitential garb, in favour of greater adaptability and mobility; they also renounced capitular government with its democratic character in favour of a more monarchical regime; and their vows were in general of such a nature that separation from the order was easier than had been usual in similar Catholic groups. The Society of Jesus was to be above all an order of apostles "ready to live in any part of the world where there was hope of God's greater glory and the good of souls." Loyola insisted on long and thorough training of his followers. Convinced that women are better ruled by women than by men, after some hesitation he resolutely excluded a female branch of the order. The special vow of obedience to the pope was called by Loyola "the cause and principal foundation" of his society.

Loyola and his work were much admired during his lifetime. But he also met with opposition in the church and outside it. His innovations in the religious life were criticized and, while Protestant leaders early came to look on him as one of their principal opponents, some Catholics accused him and his followers of being secret Protestants.

As general, Loyola was frequently sick. In Jan. 1551 he became so ill that he begged his associates, though to no purpose, to accept his resignation as superior. Despite his condition he continued to direct the order until his death on July 31, 1556. Since his days at Manresa, Loyola had practised a form of prayer which in his last years appears to have rivaled that of the greatest mystics.

Ignatius Loyola was beatified by Pope Paul V in 1609 and canonized by Pope Gregory XV in 1622; his feast day is July 31. In 1922 he was declared patron of all spiritual retreats by Pope Pius XI. His enemies no less than his friends agree that Ignatius Loyola was a maker of history. Scores of books could be cited in proof of this statement. The spirit of Loyola lives on in the Society of Jesus and in the Jesuit *Constitutions*, which still regulate the lives and aspirations of over 30,000 Jesuits, scattered through most countries of the world. *The Spiritual Exercises* molded 27 canonized saints, three of them, Francis Xavier, Peter Canisius and Francis Borgia, intimates of Loyola. His achievements and those of his followers form a chapter in the history of the Roman Catholic Church which cannot be neglected by those who desire to understand that institution.

See also JESUS, SOCIETY OF.

BIBLIOGRAPHY.—The sources of the life of Ignatius have been published in more than 20 volumes in the *Monumenta Historica Societatis Iesu* (1894–1918; 1934–48). Loyola's *Autobiography* can be found in *St. Ignatius' Own Story*, trans. by W. J. Young (1956); *The Spiritual Exercises*, trans. by L. J. Puhl (1951).

Lives by Catholics include A. Astrain, *A Short Life of St. Ignatius* (1928); P. Dudon, *St. Ignatius of Loyola* (1949); J. Brodrick, *The Origin of the Jesuits* (1940); and *St. Ignatius Loyola, the Pilgrim Years* (1956). Lives by non-Catholics are: H. D. Sedgwick, *Ignatius Loyola* (1923); R. Harvey, *Ignatius Loyola* (1936); P. Van Dyke, *Ignatius Loyola* (1926); R. Füllöp-Miller in *Power and Secret of the Jesuits* (1930) and in *The Saints That Moved the World* (1945). (E. A. R.)

LOZÈRE, a highland *département* of southern France, lies astride the Atlantic-Mediterranean watershed in the Massif Central, and consists of higher, inland portions of the old province of Languedoc (*q.v.*). Area 5,168 sq.km. (1,995 sq.mi.). With only 81,868 inhabitants in 1962, it is the least populous of all the *départements* of France. To the east it is bounded by Ardèche, to the southeast by Gard, to the west by Aveyron and to the north by Cantal and Haute-Loire. The northern and eastern parts consist of high granite plateaus. In the southeast is the Lozère portion of the Cévennes, the heavily dissected, uptilted edge of the Massif Central. Farther north the slablike ridge of Margeride, which separates the Allier drainage from that by westward flowing tributaries of the Garonne system, the Truyère, Lot and Tarn, exceeds 5,000 ft. In the southwest of the *département* the Lot and Tarn cross the almost deserted, high limestone plateaus of the Causses by labyrinthine gorges with precipitous walls. Both the Causse de Sauveterre, between the Lot and the Tarn, and the Causse Méjean south of the Tarn rise well above 3,000 ft.

Infertile soils and the severe, wet climate restrict farming activities on the crystalline highlands, and the highest parts are moorland, with only the beginnings of afforestation. The lower

plateaus of Bas Gévaudan, lying west of the Margeride, and the basalt plateaus of Aubrac that cap the older crystalline basis in the extreme west of the *département* offer better prospects for farming. Freed by modern transport from the need to grow all their own food, the farmers concentrate increasingly upon cattle raising. Cultivation of rye and chestnut, once staple features of the diet, is in decline. Potatoes have increased in importance, but most cultivation is concerned with fodder crops. The crystalline plateaus are no longer much visited, as in the past, by transhumant flocks of sheep from the Mediterranean coastlands, but local sheep are the basis of the economy in the Causses, now directed toward the production of sheep's milk for making Roquefort cheese. Apart from some scattered workings of silver-lead and zinc ores, mineral wealth is unimportant and there is little manufacturing. The harnessing of the Truyère for hydroelectric power, however, made possible the post-World War II establishment of electrometallurgy at St. Chély-d'Apcher.

At Mende, the capital and largest town (pop. [1962] 7,647), a woolen industry survives. Mende is the seat of the bishopric. The old town, dominated by its cathedral, is situated where the Lot enters the Causses. Mende and Florac are the centres of the two *arrondissements* into which the *département* is divided. For the administration of education and of justice the *département* comes under Nîmes. (AR. E. S.)

LUANDA (formerly SÃO PAULO DE LUANDA; LOANDA), the chief city and capital of the Portuguese overseas territory of Angola in west Africa, and also the capital of the coastal district of Luanda. The city, founded in 1576 by Paulo Dias de Novais, is one of the most attractive in west Africa. Its population of 189,590 in 1955, including 34,250 whites, increased to 224,540 in 1960. It lies on the coast about 40 mi. N. of the Kwanza river estuary. The higher part is generally residential and the lower is industrial and commercial. The old fortress of São Miguel looks over Luanda Island beyond the port. Luanda port is the second in Angola after Lobito. It has modern equipment and about 1,000 yd. of wharfage, can accommodate ships of 37 ft. draft and is linked with the hinterland by the Luanda railway. Luanda, once an important centre of the slave trade, has been the administrative centre of Angola since 1627 and is the seat of a Roman Catholic archdiocese. It is also commercially important, with large exports of agricultural and mineral products and with secondary and manufacturing industries. Petroleum was discovered nearby in 1955, and a refinery with an annual throughput of 100,000 tons was built at the north end of Luanda bay. Power is obtained from a hydroelectric plant completed in 1954 at the Mabubas rapids, about 40 mi. N.E. on the Dande river. The Luanda railway extends inland to Quela, about 450 mi. E., and Luanda airport is served by international and local airlines.

LUANDA DISTRICT had a population (1960) of 349,764, including approximately 58,000 whites. Area 13,363 sq.mi. Much of it is low lying, with a humid tropical climate and fertile soil. The principal crops are cotton, sugar cane, palm oil and kernels, oilseeds, cereals, tobacco, coffee and fruits. The waters offshore are rich in fish. At Dande bituminous asphalt and mica are exploited. Administratively, the district consists of the *concelhos* (counties) of Ambriz, Dande, Icolo e Bengo and Quicama, and the circumscription of Luanda. After Luanda, the chief towns are Ambriz, Caxito, Catete and Muxima. (A. A. G. P.)

LUANG PRABANG, a town and river port in Laos located on the left bank of the Mekong at the confluence of small streams draining from the mountainous borders of south China and North Vietnam, 130 mi. N.N.W. of Vientiane. Traditionally founded by Indian Buddhist missionaries, it is the capital of Luang Prabang province which has an area of 14,363 sq.mi. and a population (1959 est.) of 322,100. The town contains approximately 25,000 persons and, though it was the seat of kings of Luang Prabang and remains the royal capital (*see* Laos), it is in reality little more than a poor market town trading in fish and forest products. Its buildings are mainly of wood and laid out very openly along unmetaled streets. Most shops are owned by Chinese who are the chief users of the caravan routes northward. The surrounding countryside is peopled largely by subsistence farmers growing poor

crops of *padi* (rough rice) and a little maize (corn). Luang Prabang has a tropical inland location in a mountainous setting and in winter temperatures sometimes drop below 10° C. (50° F.). Rainfall averages only 53 in. annually with a maximum in August. During the dry season, November to March, the skies are clear and the air crisp. (E. H. G. D.)

LUANSHYA, a town in the Western province of Zambia, Africa, known as "the garden town of the copper belt," is situated 4,250 ft. above sea level, 21 mi. S.W. of Ndola. Pop. (1961/63) 68,120. The public township contains residential, business and industrial areas and there is a separate mine township (Roan Antelope). A rail terminus, Luanshya is also connected by macadamized roads to the other copper belt towns and has an airfield; the nearest airport is Ndola. Besides copper mining there are steel, welding and general machine shops, and concrete, furniture and clothing industries. (L. R. B.)

LUBA. The Luba people, or Baluba, are a Bantu group of the southeastern Republic of the Congo. They inhabit a wide area extending from the extreme south of Sud-Kivu province through Nord-Katanga and Sud-Katanga provinces to the south-east of Kasai-Oriental province. The name Luba applies to a variety of tribes which, although of different origins, speak closely related languages, exhibit many common cultural traits and participate in a common political history founded on the beginnings (16th century) and breakdown (17th century onward) of the Luba empires. The population (1960s) amounts to more than 1,500,000. Three main subdivisions may be recognized: the Baluba-Shankaji of Katanga, the Baluba-Bambo of Kasai (both patrilineal and virilocal and speaking respectively Kiluba and Ciluba) and the Baluba-Hemba of northern Katanga and southern Kivu, who are either matrilineal or bilineal, practice virilocal marriage and speak Kiluba. All are historically, linguistically and culturally linked with other Congo peoples, such as the Benalulua, the Bakwaluntu, the Benakanyok and the Basonge. The Shankaji branch is also connected with the early founders of the Lunda dynasty. Luba tribes are also mixed with other groups of miscellaneous origin. Since the 17th century there has been an ever-growing expansion of Luba-Bambo in Kasai province.

The Luba are savanna and forest dwellers; they practise hunting, food gathering and agriculture (manioc, maize) and keep small livestock; they fish the Congo and its main tributaries intensively. High marriage payments (bridewealth) are common. Polygyny, levirate marriage and sororate exist, but not cross-cousin marriage; parallel and cross-cousins are called by the same terms as brothers and sisters. Luba are subdivided into large dispersed clans and localized lineages; the latter form exogamous units and may be linked by an elaborate system of political and ritual status. In the 16th and early 17th centuries most of the Luba were ruled by a paramount chief (*mulopwe*), although smaller independent chiefdoms already existed. The breakdown of the empire resulted in the development either of smaller chiefdoms or of small autonomous local lineage groups.

Luba practise circumcision and women's initiation; they have associations for hunting, magic and medicine. They have a strong belief in a supreme being and worship ancestors and natural spirits. Literature, including epic cycles, is well developed. The Shankaji and Hemba are renowned wood-carvers, especially of anthropomorphic figures, ceremonial axes and headrests.

Burssens, *Manuel de Tshiluba* (1946); H. W. Beckett, *Hand Book of Kiluba (Luba-Katanga)* (1952); P. Lumumba, *Congo, My Country*, Eng. trans. by Graham Heath (1962). (D. P. Bl.)

LUBBOCK, seat of Lubbock county, is the industrial, financial and commercial hub of the south plains area of western Texas, U.S., about 100 mi. S. of Amarillo. The first settlers were ranchers who arrived in the late 1870s. The town, laid out in 1891, when Lubbock county was created out of Bexar territory and named for Tom S. Lubbock, a Confederate soldier, was incorporated in 1909, and adopted a mayor-commission-manager form of government in 1917.

Although Lubbock has a diversified economy, regional agricul-

ture (cotton, grain sorghums, Sudan grass, wheat and vegetables) supported by irrigation from underground water is its base. The south plains produce almost one-fifth of the nation's cotton and Lubbock is one of the world's leading inland cotton markets and cottonseed-oil centres. Other major industries include poultry and dairy products, feed mills, cattle feeding, irrigation pipes and oil. The city is also the regional centre for government offices and medical care.

Cultural institutions include Texas Technological college (1923), Lubbock Christian Junior college, the West Texas museum and two public libraries. The annual Panhandle South plains fair, a large coliseum, a number of city parks, Mackenzie State park (548 ac., with its "prairie dog town") and Buffalo lakes provide recreational facilities.

After World War II, Lubbock witnessed a rapid growth with its population increasing from 31,895 in 1940 to 128,691 in 1960. Population (1960) of the standard metropolitan statistical area (Lubbock county) was 156,271. For comparative population figures see table in TEXAS: Population. (E. We.)

LÜBECK, a city and Baltic port of Germany which after partition of the nation following World War II was in the *Land* (state) of Schleswig-Holstein, Federal Republic of Germany, was formerly a state of the German empire (a Free Hansa City, later the Hansa city of Lübeck). On an inlet of the Baltic on the lower course of the Trave river, the city lies directly west of the boundary between the Federal Republic of Germany and the German Democratic Republic (Mecklenburg). Pop. (1961) 235,200. The city proper lies on an island formed by the Trave and Wakenitz rivers and the Elbe-Lübeck canal; suburbs, which are incorporated in the city and are still often rural in character, lie on the other side of the watercourses and along the Trave river to its mouth. One of these suburbs is the seaside resort of Travemünde. The Trave is navigable and has several harbour basins; the Elbe-Lübeck canal was constructed in 1900. Rail connections include those with Hamburg, Eutin-Kiel and Neustadt-Grossenbrode (rail-ferry to Denmark). A motorway connects Hamburg, Lübeck and Travemünde. In the summer there are regular sea passenger services to Sweden, Denmark and Finland.

Lübeck is West Germany's most important Baltic port, having shipping and trade connections especially with Sweden, Finland and Denmark. The chief imports are ores, coal, timber and cattle, and the exports are salt, iron, coal and chemical products. Well-known Lübeck specialties are associated with the wine trade and the production of marzipan, a confectionery. Industrial installations include blast furnaces, several large shipyards, engineering works and fish-processing plants.

In 1138 Old Lübeck, on the Lower Trave, a Slav precursor to the present city, was destroyed. Count Adolf II of Holstein founded the town on its present site in 1143, when he brought in colonists from western Germany and Flanders. The first settlement was burned down in 1157, and in 1159 was redesigned and built as a city foundation by Henry the Lion, duke of Saxony. This first Baltic town built on the west European pattern quickly flourished because of its excellent geographical position, and about 1200 was already developing into the centre of north European trade between Scandinavia and the Baltic countries, on the one hand, and western Germany, Flanders and England on the other. Most of the younger towns on the Baltic were strongly influenced by Lübeck, not only in their economic and legal systems but also in their style of architecture. In 1226 the town was raised by Emperor Frederick II to the status of free imperial city. Lübeck took up the leading position in the Hanseatic league, the community of towns still forming early in the 14th century; while abroad, Lübeck merchants played a special role in the German commercial settlements in London (the steelyard), Bruges, Bergen and Novgorod. During the middle ages Lübeck was one of the largest and most important towns in central Europe. The decline began in the 15th century as the states of west and north Europe became politically and economically more powerful and independent, and the main volume of European trade shifted more and more to the west. In the years 1530-37 the rash war policy of the demagogue burgomaster Jürgen Wullenwever (1492-1537) to-

ward the Netherlands, Denmark and Sweden led to the collapse of Lübeck's old position as a great power. In the following centuries Lübeck sank to an economic position of the second rank, to that of a mere Baltic port. But as such it has retained considerable importance up to the most recent times in its traffic with Scandinavia, the Baltic states and Russia.

Politically the town continued as a free city within the old German empire, and after a short interval (1811–13) when it was attached to Napoleon's empire, it became a member state of the German confederation, in 1866 of the North German confederation, and in 1871 of the new German empire. Lübeck also kept its status as a *Land* after World War I, indeed right through the period of the Weimar republic, and in the first few years of Hitler's regime. However, by a decree of Hitler's government Lübeck lost its ancient independence in 1937, and was incorporated in the Prussian province of Schleswig-Holstein (from 1946 the *Land* of Schleswig-Holstein).

From the beginning of the 20th century the economic situation of the town was critical, especially following the opening in 1895 of the Kiel canal, which substantially favoured competition from the west in the Baltic area; other factors disturbing to the economy were the political and economic upheavals in the area after 1918. World War II and its consequences aggravated them. An air raid in 1942 destroyed about one-quarter of the inner town and damaged a substantial proportion. After 1945 thousands of refugees flocked into Lübeck from the east and increased the population, which was 150,000 before World War II, by more than a third. The lowering of the "iron curtain," cutting off communication with the east, made Lübeck a border town and deprived it of a large number of its export partners and of its hinterland. The effect on the town's economy was an increasing shift of emphasis from the export trade to industry. For early history, *see* also HANSEATIC LEAGUE.

The inner town, although partially destroyed by the air raid in 1942, retained much of its medieval character. Of the medieval works of architecture, the five main churches are outstanding: the cathedral, St. Mary's, St. Peter's, St. Jacob's and St. Giles' (all 13th–14th centuries); also the monastery church of St. Catherine (14th century) and the Hospital of the Holy Ghost (end of the 13th century). Several of the churches sustained war damage in the air raid but for the most part have been restored. Among the secular buildings are the *Rathaus* (town hall) (13th–16th centuries), the House of the Seaman's Guild, the Schabbelhaus and numerous private houses of special interest, and there are medieval city gates that have been preserved (Holstentor, Burgtor). Three museums (St. Anne's museum, the Behnhaus and Holstentor) contain works of value in art or social history; they include works of the Lübeck artists Bernt Notke, Hermann Rode (both 15th century) and Johann Friedrich Overbeck (1789–1869). In the city archives the charters and deeds of the Hansa are also preserved. The two writers Heinrich and Thomas Mann were of a Lübeck merchant family; Thomas Mann's novel *Buddenbrooks* gives an excellent portrayal of that Lübeck milieu in the 19th century. Another native of the city was the portrait painter and court artist of Charles II and of James II, Sir Godfrey Kneller.

LUBECKI, KSAWERY DRUCKI (1779–1846), Polish statesman, the restorer of the finances of the "Congress kingdom" under the Russians after the Napoleonic Wars, was born in St. Petersburg on Dec. 28, 1779, of a princely family descended from the ancient Russian ruling house of Rurik. As an officer in the Russian service the prince took part in A. V. Suvorov's Italian campaign of 1799. In 1813–15 he was a member of the provisional government of the duchy of Warsaw, then under Russian occupation. From 1817 to 1821 he led successful negotiations in Berlin and Vienna for the settlement of the Polish foreign debt.

In July 1821 the prince was appointed minister of the treasury of the kingdom of Poland at a time when its finances were in a critical state. He restored public confidence, restraining numerous abuses and efficiently collecting overdue taxes. In three years he balanced the budget, basing it chiefly on indirect taxation. Using budget surpluses for promoting industry, he developed state mines

and foundries and helped the growing textile industry. The Land Credit society (1825) and the Bank of Poland (1828) were also his creations. Having secured an independent position in the government as well as the Russian emperor's confidence, he steadfastly defended Poland's autonomy, though he disregarded the constitutional freedoms and opposed revolutionary trends. After the national insurrection of Nov. 29, 1830, he tried to maintain the movement within legal limits; then went to St. Petersburg to negotiate with the emperor Nicholas I. His mission failed, and Lubecki remained a passive witness of the Polish defeat. He spent the rest of his life in St. Petersburg, where in 1832 he was appointed a member of the state council. He died there on May 23, 1846. Lubecki's correspondence was published by S. Smolka, four volumes (1909).

See S. Smolka, *Polityka Lubeckiego przed powstaniem listopadowym* (1907). (S. K.)

LUBLIN, a town in eastern Poland and capital of Lublin *województwo* (voivodship), is located 105 mi. S.E. of Warsaw on the Bystrzyca, at the intersection of important routes from Cracow and Warsaw to the U.S.S.R. Pop. (1960) 180,700. The trade settlement, which existed in the 10th century, flourished and acquired town rights in 1317. Because of its location on the borders of the Polish and Lithuanian lands it became a meeting place for joint congresses, and in 1569 the Act of Union between the two countries was signed there. In 1795 it passed to Austria after the third partition of Poland. Between 1809 and 1815 it was incorporated in the Warsaw kingdom, and from 1815 was included in the Polish kingdom, dependent on Russia. Following the re-emergence of independent Poland in 1918, the first independent Polish government was proclaimed in Lublin. After World War II it was the provisional seat of the Polish Committee of National Liberation and later of the temporary government.

Industries include meat, tobacco and sugar factories, a large hop-drying plant, flour mills and breweries. Agricultural implements and, since World War II, automobiles are also manufactured. Lublin is the cultural centre of eastern Poland, containing five higher educational establishments, two theatres, three museums, a philharmonic hall and a theatre for operettas. Despite damage sustained during World War II, Gothic and other buildings have survived, including the Castle chapel (with fine 15th-century murals), many fine churches (including a 16th-century cathedral), three town gates and many houses and palaces of former Polish nobles. One of the town's museums, in the suburb of Majdanek, is situated on the site of the former concentration camp established by the Nazis in 1941. The Majdanek camp, second largest after Oswiecim (*q.v.*), was one of the most notorious extermination camps. It has not been possible to establish the total number of persons murdered, since the Germans burned the bodies in furnaces and before retreating destroyed their records, but about 820,000 pairs of boots and shoes were found in the camp. The number of Majdanek victims was estimated during the Nürnberg trials at 1,500,000.

LUBLIN *województwo* borders (east) the U.S.S.R. along the Bug river and (west) the Vistula. Area 9,584 sq.mi. Pop. (1960) 1,799,900. It comprises highlands in the south and plains to the north. The excellent soils of the highlands provide for an agricultural economy where wheat is mostly grown, as well as sugar beets, hemp and hops (more than 60% of Poland's total production) and tobacco. Farming is also the main occupation of the inhabitants of the plain, though the soils there are poorer, and the crops are mainly rye and potatoes. The agricultural character of the region is evident in the high percentage of cultivated land (more than 70%). The voivodship is also important for the breeding of cattle, pigs, sheep and horses. Industry is poorly developed because of the scarcity of mines and raw materials. Good facilities are available for food processing; there are metal industries and large cement works at Rejowiec and Chelm. After World War II metal industries were developed in Lublin, Swidnik, Krasnik and Poniatowa. During the region's most prosperous period in the 16th century, many buildings were erected in the style known as Lublin Renaissance. The finest are found in the old city of Zamosc (in the northeast of the voivodship), which was

erected by the Zamoyski family on a uniform plan and is well preserved; and Kazimierz, a favourite spot for artists on the Vistula.

Only about one-fifth of the population is urban. The most important towns include (pop. 1960): Chelm (31,000), Zamosc (28,000), Biala Podlaska (20,000), Pulawy (13,400), Swidnik (12,700), Hrubieszow (12,300), Krasnik (12,100), Miedzyrzec Podlaski (11,000), Lukow (11,000) and Krasnystaw (11,000).

(T. K. W.)

LUBRICATION concerns itself with the reduction of frictional resistance between two contacting surfaces forced to slide over one another. As secondary objectives lubrication tends to minimize wear and prevent corrosion. Lubrication is accomplished by inserting a thin film of lubricant between the sliding surfaces; thus lower fluid friction is substituted for the higher dry, metal friction. Any material placed between the surfaces to lessen friction is a lubricant. (See FRICTION.)

In a machine civilization, lubrication is vitally important. Friction wastes energy. It has been estimated that over 30% of the energy generated is consumed in friction; i.e., heat. Lubrication was probably first practised when primitive man noted the eased skidding that resulted, because of sap lubrication, when the bark was removed from the trunk. From this crude start to the operation of delicate instruments on a man-made satellite, man's most persistent problem has been the reduction of friction and wear. Only in the 20th century, however, did he begin to understand the mechanism of friction and lubrication.

As man continued to analyze the phenomena, the art of lubrication gradually evolved into an exact science. Not long ago the task of lubricating the crude machines of industry was just a messy chore. A low-rated employee equipped with little more than an oil-can would irregularly proceed to oil all bearings with often only a single oil. Mass production, higher speeds, larger machines, long space flights—all these have changed the chore into a scientifically engineered phase of preventive maintenance. Better lubricants, special additives and automatic dispensing systems are among improvements that are receiving continuous attention.

Dispensing.—The best lubricant is useless until it is applied properly to the bearing, or gear, or guideway needing it. Where points to be lubricated are few and frequency of application is not critical, manual methods are sufficient. Modern machines, however, contain many bearings, precision-built to operate under severe conditions. The lubricant must, therefore, be applied with regularity, according to a precisely controlled plan: it is essential to get the right lubricant to the right place at the right time. Consequently, application by use of mechanical means is common procedure.

Many varieties and types of dispensing devices are available, ranging from simple units that lubricate a single bearing to fully automatic central systems capable of lubricating all the machines in a plant.

The oilcan, though providing unreliable, inefficient and irregular lubrication is proper in some cases. Rough units such as chains, hoists and farm machinery are appropriate for oilcan lubrication. Where the oil fed to the bearing should be partly controlled, drop feed, wick feed, bottle oilers and ring oiling are used (fig. 1). Bath and splash methods are effective in heavy, slow machinery.

For positive, adjustable, reliable lubrication, mechanical force feed systems (fig. 2) are best. Oil fog lubrication is one of the latest techniques being developed to transmit the lubricant to the surface needing lubrication.

History.—The major portion of industrial lubricants are derived from crude petroleum. The history of lubrication, therefore, closely parallels the growth of the petroleum industry. Actually petroleum is not a new discovery. Ancient Assyrians and Egyptians, and later Greeks and Romans, all used petroleum for lighting and embalming.

American Indians used petroleum medicinally. The colonists, however, when discovering it while drilling for salt, considered it a nuisance and poured it away as waste. In 1859 the Drake well in Pennsylvania was drilled to 69 ft. and produced 25 bbl. of crude oil daily; in 1901 the Lucas gusher, drilled in the Spindler-

FIG. 1.—SEMI-AUTOMATIC LUBRICANT DISPENSERS: LEFT, GRAVITY FEED OILER; RIGHT, WICK FEED OILER

top field, emitted up to 100,000 bbl. daily, and signaled the abundant availability of petroleum and its products. After this time petroleum rose to become mankind's major source of lubricants. Thus, the internal-combustion engine, the automobile, the airplane, the diesel train and the turbojet were all made possible by the use of petroleum, both as a fuel and as a lubricant. It also became possible to design production machinery for larger capacity and higher speed because improved lubricants could be modified to satisfy more severe operation conditions.

Lubricants.—If the function of reducing resistance between surfaces sliding over one another is to be performed satisfactorily for a reasonable length of time, the lubricant must possess particular properties. Thus, a lubricant must be a versatile, multi-functioned product. It must reduce wear as well as friction; it must also carry the heat away, prevent corrosion, disperse contaminants, inhibit foam formation and remain intact under severe requirements. In addition it must flow through the bearing easily in order to perform all its functions well.

Lubricants may be grouped into five convenient categories. These are (1) petroleum or mineral oils; (2) fixed or animal oils; (3) synthetic lubricants; (4) solid lubricants; and (5) greases.

Petroleum Lubricants.—Petroleum lubricants are produced from crude oil, a complex mixture of hydrogen, carbon and oxygen plus traces of nitrogen and sulfur. Clay, water, chemical elements, resins and mineral salts are also often present in the crude oil. Obviously then, refining becomes necessary. Distillation, known as fractionation, is the key step in the refining process. In order to convert the crude into the finished lubricant many other steps are performed. Dewaxing, filtering, solvent refining to remove as-

BY COURTESY OF MARZEL DIVISION, HOUSDAILE INDUSTRIES, INC.

FIG. 2.—MULTIPLE-FEED AUTOMATIC MECHANICAL LUBRICATION SYSTEM

phalts, cracking to convert heavy into light oils, blending to meet the many special requirements, and the addition of chemical compounds to enhance, improve or impart desirable characteristics to the lubricant stock are other steps.

Each of the crude oils originating in the earth's petroleum fields differs somewhat in composition from every other. Many variations in refining are therefore needed. However, the process is so advanced that by the time the finished lubricant is ready for the bearing, the distinction between crudes has mostly vanished.

Fixed Oils.—These are animal and vegetable extracts. Animal oils (tallow, neat's-foot, whale, lard, cod-liver, *degras*) are produced by heating the fatty tissue. Vegetable oils, on the other hand, are extracted by pressing and chemically treating seeds of castor, rape, olive, cotton, peanut, coconut and palm. These oils can seldom be used directly as lubricants because they are quite unstable at ordinary operating temperatures, oxidizing into a varnishlike sludge. Their principal use is in the manufacture of greases and as agents or additives in mineral oils.

Fatty acids contain oxygen and fatty acids in addition to the basic hydrocarbon constituents. When mixed with mineral oils, the fatty acids appear to activate the mineral oil molecules into more effectively oriented layers, an action that results in a higher oiliness property with the tendency to wet and adhere to the metal surface even under high pressure.

Oiliness is particularly important in thin-film lubrication where it helps to prevent direct metal-to-metal contact and so reduces friction and wear.

Synthetic Lubricants.—Although costlier, synthetic oils have found extensive use in the second half of the 20th century. Better stability at higher temperatures and an improved viscosity index (the higher this index the smaller the change in viscosity with temperature) at ordinary temperatures are the principal reasons. Furthermore when many of these synthetic oils undergo thermal decomposition, the resulting products are fluids quite similar to the original product or, otherwise, are volatile materials that evaporate without depositing gummy residues.

Five general types of synthetic lubricants and lubricant agents are in common use. These are the polyalkylene glycols, the silicones, the polymer oils, the organic chlorine compounds and the diesters. Of these the polyalkylene glycols are probably most used because of their inherently wide temperature tolerance, their low solvent action on rubber and their high resistance to sludge formation. A widespread application exists in this group—from 400° to 500° F. temperatures in industrial kiln cars to low temperatures in liquefied hydrocarbon gas pumps. An interesting experience illustrating the unusual antiwear property of glycols is illustrated by their use on highly loaded gears. In a controlled test, gears lubricated with a mineral oil pitted severely in six months while similar gears lubricated with a glycol lubricant showed only traces of wear after a full year of operation.

The silicones also possess good thermal stability and general chemical inertness. The silicones are primarily alkyl polymethyls and polymethyl phenyl siloxanes. Use over the 10° to 500° F. temperature range is common. They are more critical, however, than mineral oils with respect to metal combinations. On the other hand, they inhibit foaming almost magically.

The polymer oils, derived from the polymerization of low molecular weight paraffins, are used primarily as carriers of active lubricating ingredients. They are so used extensively because of their very clean burn-off properties at temperatures as high as 750° F.

The chlorine lubricants or Aroclors are not good lubricants by themselves but are most effective additives as extreme pressure agents. The esters of dicarboxylic acids, the fifth group, serve well in various demanding applications. To date their major use has been in high-quality instrument oils and specialized greases.

Solid Lubricants.—The solid lubricants are of mineral and chemical compound origin. Graphite, talc, soapstone and mica are representative of the mineral group. Molybdenum disulfide is the most important chemical compound type. The solid lubricants are good for temperatures at which liquids become impractical. The direct application of solid lubricants is, in general, quite difficult.

FIG. 3.—GRAPHITE LUBRICANT PRESSED IN BRONZE BEARING

They are therefore usually suspended in volatile, liquid carriers that flash off at elevated temperatures, leaving a thin deposit of the solid-lubricant.

Natural graphite, a black, lustrous mineral, is usually used in the dry form. Sometimes a binder is mixed in to form a paste that is pressed in grooves or layers in bronze and babbitt-bearing sleeves (see fig. 3). Colloidal graphite is a soft, greasy substance, almost chemically pure. It is much easier to "carry" in this small particle size and proves itself a good lubricant in the high-temperature range.

The soft molybdenum disulfide is extracted from a natural ore. The favoured solid lubricant over a wide temperature range, it has been used successfully in liquid nitrogen valve systems at temperatures as low as -300° F. Its use has been reported at 1,600° F in a vacuum and at 2,400° F. in argon atmospheres. In normal atmospheres it is stable up to 750° F. The National Aeronautics and Space administration (NASA) claims the most effective molybdenum disulfide (molykote) surface to be one that is obtained when a bearing is smeared with the molykote suspended in a fluid, baked at around 650° F., and finally buffed to a high finish.

Certain metallic dispersions can also be considered solid lubricants. Finely powdered lead and indium have been dispersed in oil and other vehicles with interesting lubricating results. Thin metallic platings of copper, indium and aluminum have also been tried with some success. In addition several chemical coatings, deposited as reaction products, have been found to possess lubricating properties.

Greases.—Grease is a plastic solid, a mixture of saponified fat in a liquid lubricant. Plastic solids (see *Theory*, below) do not flow at ordinary temperatures. Officially the American Society for Testing Materials (A.S.T.M.) defines greases more broadly, "Lubricating Grease: A solid to semisolid product of dispersion of a thickening agent in a liquid lubricant. Other ingredients imparting special properties may be included." (American Society for Testing Materials, *Standard Definitions of Terms Relating to Petroleum*, 1959.) Greases vary extensively both in composition and in physical properties.

Many different soap bases—calcium, lithium, sodium, barium, silica—are used in combination with various petroleum oils, as well as with some of the synthetic lubricants.

In general, greases are inferior wherever liquid lubricants can be used. Greases suffer greater power losses because of the thickening soap. For the same reason greases are used where a liquid lubricant cannot be constantly supplied and where lubricant leaks or spattering may be objectionable or even detrimental to the product, such as on food or cloth. Also in rough, heavy machinery, where boundary conditions are likely to exist, grease lubrication is preferred. Comparative advantages of grease and oil are shown in Table I.

The lubricating power of greases depends on both the liquid and soap constituents. The soap base acting as a sponge absorbs the oil to release it to the bearing during operation by squeeze action. On the other hand, the soap molecules are adsorbed into the metal

TABLE I.—Comparative Advantages of Grease and Oil in Bearings

Advantages of Grease	Advantages of Oil
1. Maintenance may be reduced: no oil level to maintain; regreasing is infrequent.	1. Oil is easier to drain and refill. This is important if lubricating intervals are close together.
2. Proper grease quantity is easily confined in housing. Simplifies design of bearing enclosure.	2. Use of oil makes it easier to control the correct amount of lubricant.
3. Freedom from leakage is important in food, textile and chemical industries.	3. Same lubricant may be used on other types of bearings on the same machine.
4. Improves efficiency of labyrinth enclosures, gives better bearing protection.	4. If bearing must operate under high temperatures, conditions favour oil.

Adapted from J. J. O'Connor, "Bearings and Lubrication," *Power* (Dec. 1951)

to hold the rubbing surfaces separated and thus lubricated. Probably where bearing clearances are comparatively large the liquid constituent is more important, while at smaller clearances the molecular soap layers provide the lubrication.

Greases may be divided into five groups: (1) the water-resistant; (2) the water-soluble; (3) the multipurpose; (4) the synthetic; and (5) the special purpose greases.

(1) Calcium forms the base of the water-resistant group. Lube oil and a small amount of stabilizing water are the other constituents. In general these water-resistant greases are satisfactory up to about 200° F. as a maximum. Above this temperature the water will boil off, which allows the oil to separate and "bleed" off, leaving the sticky, gummy soap.

When not stabilized with water the grease may work at slightly higher temperatures. Aluminum oleate or palmitate is also used as the base.

(2) The water-soluble greases contain a sodium hydroxide base. Since these greases offer very little resistance to water-washing, they cannot be used where water or steam is present. However, because of the absence of water they may be used at temperatures up to 300° F.

(3) The multipurpose members contain either a barium or a lithium base. Both bases make the grease reasonably water resistant—better than sodium but not quite as good as the calcium greases. In continuous service the multipurpose greases may be used up to about 350° or 400° F. The need for this group arises, of course, from the desire to have a single grease serve many purposes, a good example being automobile servicing.

(4) The synthetic greases are the latest development in the industry. Some contain standard soaps in synthetic oils, while others are mixtures of synthetic thickeners (bases) in petroleum oils.

The silicones, on the other hand, are greases in which both the base and the oil are synthetic. The synthetic greases are made in water-soluble and water-resistant forms. As a result they may be used over a wide temperature range. In addition the synthetics can be used in contact with natural or other rubbers because they are quite inert to these materials.

(5) In the attempt to obtain some especially desirable characteristic two or more soap bases are used to produce the special purpose greases.

In some cases additives, like extreme pressure agents, are used to gain the special property.

Additives.—Chemical compounds are added to lubricants to improve certain properties or impart new ones. Some additives affect the lubricant chemically, others physically. Most compounds are interdependent, complementing and supplementing each other. In some cases additives affect each other adversely. As a result, additive compounding is a most complex problem. This complexity, in turn, adds much value to procedures developed and facts learned; the latest information is, therefore, seldom published or otherwise publicly expounded.

Better-known addition agents include oxidation inhibitors, detergents, dispersants, anticorrosives, foam inhibitors, antiwear agents, oiliness compounds, pour point depressors and viscosity index improvers (see *Viscosity* below). Many different classes of organic compounds, metallo organics and soaps in various proportions are used. Each lubricant producer has his own formulas and compounding techniques. Compounds containing sulfur and phosphorus, amines, phenols and naphthenates, silicone and methacrylate polymers, soaps of calcium, barium, cobalt and strontium are all typical additives.

A special group of additives are contained in boundary range lubricants. When speed is too low, high loads exist, or excessive temperatures reduce viscosity, the oil film is difficult to maintain; thus metal-to-metal contact occurs. Satisfactory lubricants are expected to remain in at least molecular thickness under these conditions. Proper additives appear to bring this about by either adsorption or reaction. In either case a layer of lower shear strength is "bonded" to the metal, providing at least minimum lubrication.

The additives of polar structure, such as lard oil, are identified

as extreme pressure (EP) agents. In turn, the product itself is called an EP lubricant.

Viscosity.—The internal friction between molecules of a fluid—liquid or gas—is, in general, viscosity. The viscosity of a lubricant is of vital importance. The friction developed in a bearing in which the rubbing surfaces are separated by a fluid film depends directly upon the viscosity of the fluid. Viscosity also impedes the flow through the bearing.

When two surfaces, moving with a velocity v relative to each other, are separated by a fluid film, the velocity of film layers is

FIG. 4.—STREAMLINE FLOW OF FLUID BETWEEN TWO PLATES. VELOCITIES ARE PROPORTIONAL TO DISTANCE FROM FIXED PLATE

as shown in fig. 4. The velocity of the layer in contact with the fixed surface is zero; that of the layer in contact with the moving layer is v . The velocity in between varies linearly.

A pull (force) must be applied to the upper plate if it is to move. Shear between successive layers of the film results from the pull. Sir Isaac Newton established in 1668 the mathematical relationship describing the shearing stress. He wrote

$$S_r = \frac{F}{A} = \mu \frac{v}{h}$$

where F is force in pounds, A is area of the film, v is velocity of upper plate in feet per second, and h is the film thickness in inches. In turn (see fig. 5) the viscosity becomes algebraically

$$\mu = \frac{Fh}{Av}$$

A unit of viscosity is thus the viscosity which requires one unit force to move one unit surface at unit velocity when one unit length away from the fixed surface. A unit viscosity in the metric system is called a poise in honour of J. L. M. Poiseuille who investigated extensively the flow of liquids in capillaries in the 1840s. Because of the size of a poise a smaller unit, one-hundredth the size, called a centipoise is customarily used. It so happens, and quite conveniently, that the viscosity of water at 68.4° F. is one centipoise. In the English system a unit of viscosity is measured in pound-seconds per square inch. It is called a reyn in honour of Sir Osborne Reynolds, father of hydrodynamic lubrication.

FIG. 5.—PLATE MOVING ON OIL FILM

Obviously the measurement of viscosity—viscometry—is quite essential. Literally hundreds of kinds of viscometers have been built and used. The most popular is the capillary tube type, which uses the principle first recognized by Poiseuille. The viscosity is obtained indirectly by measuring the pressure needed to force the liquid through the small tube, the tube dimensions and the rate of flow. An example of such an instrument, depending upon gravity as the driving force, is the A.S.T.M. modified Ostwald viscometer.

Another type of viscometer is based on Newton's viscosity law, the measurement of the force needed to pull one surface past another with a liquid between them. The rotational viscometer, in which torque is the measured quantity, is probably the best known Newton type.

Great skill is required to manipulate the above mentioned instruments. Because of this fact and the delicacy of such instruments, industry has found them unsuited for use outside the laboratory. More rugged devices, simpler in operation, have been standardized for general use. The time taken by a given volume of oil to flow through a standard orifice is measured in seconds and recorded as an arbitrary expression of viscosity. Of such efflux viscometers, the Saybolt is popular in America, the Redwood in Britain and the Engler in Germany.

Viscosity of fluids varies greatly with temperature. Because of the difficulty of mathematical expression, charts are used to present this variation. A special logarithmic ordinate scale makes the viscosity-temperature plot a straight line.

While the viscosity of liquids decreases as the temperature in-

creases, that of gases increases, curiously enough. Viscosity of a gas is determined with viscometers very similar to those already described. The viscosity of some better known fluids, lubricants included, is given in Table II.

Lubricants change viscosity with pressure as well, the viscosity increasing with an increase in pressure. The increase does not, however, become large until very high pressures are reached. At commonly used bearing pressures, therefore, the change is low enough to be negligible and so is not accounted for.

A greatly simplified, but convenient, indication of the change in viscosity within the temperature range common in bearing operation is the viscosity index (VI), which is used extensively by the lubricant industry. The oil having the smallest change in viscosity between 100° and 210° F. is assigned a VI of 100; that having the largest change has a VI of 0 (zero). A new oil, falling somewhere in between, will carry a number proportionately between 0 and 100. Since lubricants being developed in the second half of the 20th century are quite different from those used to establish the VI scale in 1929, it is possible to have a VI larger than 100 or less than 0.

Lubricant Analysis.—Lubricating oils must be tested at every step of their manufacture if the quality of the finished product is to be ascertained. Tests must also be conducted to check and insure the ability of a specific lubricant to meet particular requirements. As already indicated, the most significant test is the viscosity measurement.

Other tests regularly used are pour point, specific gravity, ash content, flash point and neutralization. Most of these tests are conducted according to A.S.T.M. procedures. The pour point is the lowest temperature at which an oil just barely flows. For application at reduced temperatures or outside, winter use, this reading is most important. The specific gravity, its weight relative to water, defines its bulkiness and gives some indication of its heavier constituents.

A measure of the amount of metal contained in an oil is obtained in the ash test.

The flash point test determines the lowest temperature to which the lubricant must be raised to evolve enough vapour to ignite when brought in contact with a flame in the presence of air. It is a safety test but it also indicates the presence of contaminants. The neutralization number, milligrams of potassium hydroxide used in neutralizing one gram of oil, is a measure of the corrosive acid or base content. This test also determines the presence of certain additives.

Other tests are conducted to check properties useful in particular applications. The colour test indicates the nature and extent of refining. The carbon residue test determines the hydrocarbon base. The foam test indicates how readily the lubricant mixes with air to form objectionable foam. How easily the lubricant will absorb oxygen is measured in the oxidation test. Rust-preventive characteristics are found in the rust test.

Greases are also similarly examined. Major tests are penetration, ash content, oxidation stability and evaporation. The penetration of a standard cone classifies greases into grades. It is a kind of viscosity measure. The amount of nonvolatile metallic compound present in the grease is measured in the ash test. Oxidation stability determines resistance to oxidation under storage conditions.

The evaporation test measures the rate at which the grease loses oil. Tests used primarily in manufacture control are the water test, soap test, oil test, alkali test and drop point.

In research and in development of new or improved lubricants, analyses other than control and application tests are essential.

TABLE II.—Viscosity of Some Better-Known Materials

Material	Viscosity at 70° F. Centipoise
Honey	1,500
SAE 50 Oil.	800
Glycerin	500
SAE 30 Oil.	300
SAE 10 Oil.	70
Ethylene Glycol	30
Kerosene	2
Water	1
Gasoline	0.4
Air	0.018
Hydrogen	0.009

Lubricants are here studied by microchemical, instrumental and even radioactive techniques. Microanalysis is the technique that makes use of very small samples, ten milligrams or less. Such microtechniques aid research greatly because large sample quantities can then be made after more favourable materials have been proven.

Fast methods of testing, which instrumental procedures permit, eliminate the tedious, time-consuming process of wet-chemistry. Furthermore, instruments often give more accurate results because much personal error is eliminated. X-ray, absorption, mass and emission spectroscopy are major instrumental devices.

Nuclear fission made available many radioactive isotopes. They can be used as tracers in wear studies. The mechanism of basic lubrication phenomena can also be studied for better understanding.

Theory.—Rheology is the science that deals with the intrinsic flow of materials. When a shearing force is applied, the material assumes a shearing strain. If the shearing stress—force per unit area—is plotted against the rate of shearing strain—strain per unit thickness—the flow phenomenon is graphically defined. Such a chart is shown in fig. 6. The “true” or Newtonian liquid (see VISCOSITY: Coefficient of Viscosity) is represented by a straight line starting at the origin. The slope of this line determines the very important property called viscosity. The non-Newtonian fluid starts at the origin also, but is partly, or wholly a nonlinear curve—the viscosity is not constant. In general, real liquids are non-Newtonian; but, if the graph is exactly or very nearly straight over the range of operation, the fluid is assumed Newtonian. When some initial shearing stress must be applied

before flow begins, the material is a plastic solid. The general plastic solid will have curved portions while the ideal or Bingham plastic solid is all straight. Greases are usually considered plastic solids. The Pascal fluid is a material, not found in nature, but theoretically interesting, which has zero viscosity; i.e., it intrinsically spreads out indefinitely. Hydraulic fluids are sometimes assumed as such.

All materials used as lubricants, whether gas, liquid or solid, are considered either Newtonian fluids or Bingham plastic solids. See also references under “Lubrication” in the Index.

LUBUMBASHI (until 1966, ÉLISABETHVILLE), a city in the Democratic Republic of the Congo, capital of the province of Sud-Katanga, lies near the southeastern (Zambian) border of the country at 4,032 ft. (1,229 m.) above sea level. Pop. (1960 est. 183,711, the majority of whom are African. Although the city is near the Equator, it has a temperate climate because of its altitude. Elisabethville (named after the Belgian queen) was founded in 1910 as an administrative centre for the copper-mining area. It has grown to be a commercial and industrial town as well. Built on a grid pattern, with wide streets, trees, and a public park, it has the Université de l'État (founded 1955, re-formed 1960), an academy of fine art, a school of music, and a museum rich in geological and ethnological collections. The Institut des Parcs Nationaux controls the Upemba National Park. Besides a Roman Catholic cathedral there are Orthodox and Protestant churches and a synagogue. The town is connected by rail with the rest of the Congo and with the principal ports of central and southern Africa. The trans-African roadway between Algiers and the Cape passes through it, and roads connect it with the Atlantic and Indian oceans. From the international airport, 4 mi. N, are regular flights to European capitals and also to some African towns.

The most important industry is connected with copper, which is mined at Kipushi and smelted at the works of the Union Minière.

FIG. 6.—RHEOLOGY CHART (SEE TEXT)

du Haut-Katanga, the country's largest mining concern. Other industries include printing, brewing, and the manufacture of flour, confectionery, cigarettes, bricks, soap, and hosiery. Neighbourhood farms supply Lubumbashi and the copper-mining areas.

Elisabethville was the centre of disaffection in Katanga during that province's attempted secession from the republic in the years immediately following independence. See also CONGO, DEMOCRATIC REPUBLIC OF THE.

LUCAN (MARCUS ANNAEUS LUCANUS) (A.D. 39–65), Latin poet who wrote the *Bellum Civile*, better known as the *Pharsalia*, a historical epic more remarkable for rhetoric than poetry though with flashes of poetic fire. Born at Corduba (Cordova), Sp., grandson of the older, and nephew of the younger, Seneca, he was educated at Rome, among his teachers being the Stoic, Cornutus, who also taught the satirist Persius. He was given a quaestorship by Nero, but it was not long before his republican opinions were outraged by Nero's tyrannous conduct, and in the year 65 he was one of the leaders (*paene signifer*, says Suetonius in his life of Lucan) in Piso's conspiracy to assassinate Nero (although Tacitus says that he was also embittered because Nero had forbidden him to give public recitations of his poetry). When the conspiracy was discovered, he was compelled to commit suicide by opening a vein. While he was dying, Tacitus records, "he remembered a poem composed by himself, in which he had told of a wounded soldier dying by the same kind of death. He repeated the lines, and that was his last utterance."

The *Bellum Civile*, his only surviving poem, is an epic of the war between Caesar and Pompey, carried down to the arrival of Caesar in Egypt after the murder of Pompey, until in the tenth book it abruptly stops. Lucan was not a great poet, but he was a great rhetorician and had remarkable political and historical insight for so young a man, though it must be admitted that his hatred of Caesar and his admiration for Pompey are both excessive. The work is naturally imitative of Virgil, his predecessor in Latin epic, but Lucan dismisses the gods from his scene, a wise precaution in a poet dealing with not too distant history.

The narrative is not always clear and is marred by overlong speeches and digressions, particularly on geographical matters, although his interest in geography does not often enable him to make his battles intelligible. He is not as dramatic as Virgil; sometimes, as in the account of Pompey's murder, because the writing is perfunctory and sometimes because he exaggerates or strains after rhetorical effect. Although the style and vocabulary are usually commonplace and the metre is monotonous, the rhetoric is often lifted into real poetry by its energy and fire, like Byron's, and appears at its best in the magnificent funeral speech of Cato on Pompey. Pompey's parting with his wife (in book v) is also very fine; and scattered through the poem are noble sayings and telling comments, expressed with the terse vigour and directness of which the Latin language has such command. As the poem proceeds, the poet's republicanism becomes more and more marked, no doubt because, as Nero's tyranny grew, he began to look back with greater longing to the old Roman republic; yet it is true that he does not make the republicanism of Pompey seem either attractive or effective. It has been said that Cato, who appears very little until after Pompey's death, is the real hero of the epic, and certainly the best of Lucan's own Stoicism appears in the noble courage and endurance of his Cato, in continuing the hopeless struggle after Pompey had failed.

LUCANIA, an ancient territorial division of southern Italy, corresponding to most of the modern region of Basilicata (*q.v.*) with much of the province of Salerno and part of that of Cosenza. Its boundaries were, approximately, the Silarus (Sele) river on the northwest, the Bradanus (Bradano) on the northeast and the Crathis (Crati) and Laus (Lao) rivers on the south; Eburum

(Eboli) and Volceii (Buccino) beyond the Silarus and Bantia (Bianzi) beyond the Bradanus were, however, also included in Lucania. Apart from the east coast and the Silarus valley, the whole of Lucania was occupied by the Lucanian Apennines.

Lucania was so called from the Lucanians (*Lucani*) who conquered it about the middle of the 5th century B.C. Before that it was included under the general name of Oenotria, applied by the Greeks to southernmost Italy. The mountainous interior was occupied by Oenotrians and Chones, while on the coasts on both sides were powerful Greek colonies which doubtless exercised a protectorate over the interior (*see* MAGNA GRAECIA). The Lucanians were a southern branch of the Samnite group, who spoke Oscan (*q.v.*). After much intertribal conflict they began to attack the Greek cities, especially Tarentum, which appealed first to Archidamus III of Sparta (killed 338), then to Alexander, king of Epirus (killed 330). In 298 B.C. the Lucanians made alliance with Rome, and Roman influence was extended by the colonies at Venusia (Venosa; 291 B.C.), Paestum (273) and above all Tarentum (272). On the landing of Pyrrhus in Italy (281 B.C.) they were among the first to declare in his favour and found themselves exposed to the resentment of Rome when the departure of Pyrrhus left his allies at the mercy of the Romans. After several campaigns they were reduced to subjection (272 B.C.). They sided with Hannibal during the Second Punic War (216 B.C.), and their territory during several campaigns was ravaged by both armies. The country never recovered from these disasters, and under the Roman government fell into decay, to which the Social War, in which the Lucanians took part with the Samnites against Rome (90 B.C. onward), gave the finishing stroke. For administrative purposes under the Roman empire, Lucania was always united with the district of the Bruttii to the south. The two together constituted the third region of Augustus' reorganized Italy.

The towns on the east coast were Metapontum, a few miles south of the Bradanus; Heraclea (*q.v.*), at the mouth of the Aciris (Agri) river; and Siris, on the river of the same name (mod. Sinni). Close to the southern frontier stood Sybaris, destroyed in 510 B.C., but subsequently replaced by Thurii (*qq.v.*). On the west coast stood Posidonia, known under the Romans as Paestum; below came Elea or Velia, Pyxus, called by the Romans Buxentum (Policastro), and Laus, near the frontier of the province toward Bruttium. Of the towns of the interior the most considerable was Potentia (Potenza). To the north, near the frontier of Apulia, was Bantia; due south from Potentia was Grumentum, and still farther in that direction were Nerulum and Muranum (Morano Calabro). In the upland valley of the Tanager (Tanagro), a tributary of the Silarus, were Atina (Atena Lucana), Forum Popilii (Polla) and Consilinum. The Via Popilia (built 132 B.C.) traversed the district from north to south, entering it at the northwest extremity; the Via Herculia, coming southward from the Via Appia and passing through Potentia and Grumentum, joined the Via Popilia in the southwest of the district; another nameless road followed the east coast.

LUCARIS, CYRIL (KYRILLOS LOUKARIS) (1572–1638), Greek Orthodox bishop and theologian, whose dream was to reform the Orthodox Church on Calvinistic lines, was a native of Crete, where he was born in 1572. In his youth he traveled, studying at Venice and Padua. In Wittenberg and then in Geneva he came under the influence of the Reformed faith as represented by Calvinism. In 1596 the patriarch of Alexandria, Meletios Pigas, sent Lucaris to Poland to lead the Orthodox opposition to the union with Rome, signed in Brest-Litovsk in that year by the Orthodox bishops. For six years Lucaris served as rector of the Orthodox academy in Vilnius. In 1602 he was elected patriarch of Alexandria and in 1620 patriarch of Constantinople.

As patriarch, Lucaris, to further his Calvinizing purpose, sent many young Greek theologians to the universities of Holland, Switzerland and England. It was one of these, Metrophanes Critopoulos, future patriarch of Alexandria, who discovered the *Confession of Orthodox Faith*, written by Lucaris in Latin and published in Geneva in 1629. In its 18 articles Lucaris professed virtually all the major doctrines of Calvinism: predestination, justification by faith alone, acceptance of only two sacraments

(instead of seven, as taught by the Eastern Church), rejection of icons, rejection of infallibility of the church, etc. In the Eastern Church the *Confession* started a controversy that culminated in 1672 in the convocation by Dositheos (*q.v.*), patriarch of Jerusalem, of a synod by which the Calvinistic doctrines were condemned. (See JERUSALEM, SYNOD OF.)

Lucaris was several times temporarily deposed and banished at the instigation of his Orthodox opponents and of the Jesuits, who were his bitterest enemies. Finally, when Sultan Murad was about to set out for the Persian war, the patriarch was accused of a design to stir up the Cossacks, and to avoid trouble during his absence the sultan had him strangled (June 1638). Several Orthodox scholars, beginning with Dositheos, attempted unsuccessfully to prove that Lucaris was not the author of the *Confession*, but the discovery by E. Legrand of the autograph manuscript of the book in Geneva made these attempts hopeless.

LUCAS, EDWARD VERRALL (1868–1938), English journalist, essayist and critic, was born at Eltham, Kent, on June 11, 1868, and after working on a Sussex newspaper studied at University college, London. He read assiduously, joined the *Globe*, a London evening paper, in 1893, and became a versatile and prolific writer. He was a frequent contributor to *Punch* and later a member of its staff, and acted as publisher's reader to the firm of Methuen, becoming chairman of the company in 1924. He edited the *Works of Charles and Mary Lamb* (1903–05), wrote the standard *Life of Lamb* (rev. ed., 1921), produced the first complete edition of the Lambs' *Letters* (1935), and was himself a distinguished light essayist. He also edited anthologies (e.g., *The Open Road*, 1899), wrote a popular series of travel books (1905–14), some essaylike novels (e.g., *Over Bemerton's*, 1908), and, in *Reading, Writing and Remembering* (1932), avoided the sentiment which sometimes marred his essays. Lucas was neither a profound nor a scholarly writer, but his work is characterized by its clarity, charm and good taste. He died in London on June 26, 1938.

See A. Lucas, *E. V. Lucas: a Portrait* (1939).

LUCAS VAN LEYDEN (LUCAS HUGENSZ or JACOBSZ; known in Italy as LUCA D'OLANDA) (1494–1533), Dutch painter and engraver, has been described as the greatest of the Dutch artists who laid the foundation of 17th-century Dutch painting. He was probably born at Leiden, where, according to Karel van Mander, he was taught by his father Huygh Jacobsz before entering the studio of Cornelis Engelbrechts. According to the same author, he painted at the age of 12 a "Legend of St. Hubert," for which he was paid a dozen florins. He was only 14 when he finished a plate representing Mohammed taking the life of Sergius, the monk. At 15 he produced a series of nine plates for a "Passion," a "Temptation of St. Anthony," and a "Conversion of St. Paul." The list of his engravings in 1510 includes subjects as various as a celebrated "Ecce Homo," "Adam and Eve expelled from Paradise," a herdsman and a milkmaid with three cows and a "Woman with a Dog." According to Albrecht Dürer's diary, Dürer met Lucas at Antwerp and exchanged the Dutchman's prints for his own and drew his portrait (British museum). The effect of this contact with Dürer is traceable in Lucas' drawings. He is likely to be the "Lucas de Hollandere, scildere," who registered at the Antwerp guild in 1522. In 1527 he made a tour of the Netherlands, giving dinners to the painters of the guilds of Middleburg, Ghent, Malines and Antwerp. The journey ruined his health; after a long illness he died at Leyden in 1533.

After Dürer, Lucas was the most important engraver of his time. Existing engravings ascribed to him number 172. He also designed a number of woodcuts, and about 20 pictures by him are in public and private collections. Early works are the "Chess Players" in the Berlin museum; the "Beheading of John the Baptist" in the Johnson collection, Philadelphia; the triptych of the "Epiphany" in the Barnes collection, Philadelphia; the triptych of the "Last Supper" in the Aachen museum; "Lot and his Daughters" at the Louvre, Paris; the "Temptation of St. An-

BY COURTESY OF THE HERZOG ANTON ULRICH-MUSEUM, BRUNSWICK, GERMANY

"SELF PORTRAIT" ON WOOD PANEL. BY LUCAS VAN LEYDEN

thony" in the Brussels gallery; and a remarkable self-portrait in the Herzog Anton Ulrich-museum, Brunswick. Then follow the paintings in a more fluent style—"St. Jerome" and "The Virgin Enthroned" in Berlin; the "Card Players" at Wilton house; the "Predication" in the Rijksmuseum, Amsterdam, and a portrait in the National gallery.

In 1522 he painted the "Virgin and Child With the Magdalen and a Kneeling Donor" (gallery of Munich). His manner was then akin to that of Mabuse. The "Last Judgment" (commissioned in 1526), in the town gallery of Leiden, is composed on the traditional lines yet some of the heads are painted with great delicacy and modeled with exquisite feeling. His last important work was a triptych now at the Hermitage at Leningrad (executed, according to Van Mander, in 1531), representing the "Blind Man of Jericho Healed by Jesus Christ." Here may be observed great finish and warm flesh tints with a gaudy scale of colours.

LUCCA (ancient LUCA), a town and archiepiscopal see of Tuscany, Italy, capital of the province of Lucca, is 21 km. (13 mi.) N.E. of Pisa by road. Pop. (1961) 89,083 (commune). Lying in the fertile valley of the Serchio with the Apuan Alps to the north and west, it is almost surrounded by hills. Lucca's central streets preserve the rectangular Roman plan, and remains of the ancient walls have been found. The Piazza S. Michele is on the site of the ancient forum and the principal market place, Piazza del Mercato occupies the arena of the amphitheatre; the arena's outer arches are visible in the surrounding buildings and the substructure of the theatre (probably 2nd century A.D.) can be traced in the Piazza delle Grazie. Spacious squares, including the Piazza Napoleone and Piazza S. Martino, provide a striking contrast with the narrow streets. The Guinigi houses, which include a high tower and the Gothic-style brick Villa Guinigi (1418) are the outstanding medieval buildings. Among many fine 16th-century palaces and

THE CATHEDRAL OF S. MARTINO, LUCCA, ITALY

later buildings are the early Renaissance Palazzo Pretorio, the podestà's residence (now the civil courts), begun in 1492 and extended in 1588, and the former ducal palace (restored in 1954; now the prefecture), begun by Ammanati in 1578 and frequently altered. World War II damage has been completely repaired and Lucca, enclosed by well-preserved and picturesque bastioned fortifications built between 1504 and 1645, retains its historic atmosphere.

Many of Lucca's numerous churches follow, though with their own local variations, the distinctive style also found in nearby Pisa; often basilican or Romanesque in structure, many have rich Gothic exterior decorations and some have quadrangular campaniles. The cathedral of S. Martino, probably founded in the 6th century, was rebuilt in the decade 1060-70 by Bishop Anselm (later Pope Alexander II); probably only the apse of Anselm's building remains. The imposing campanile was completed in the 13th century, and the Gothic nave (273 ft. by 84 ft.) and transepts (144 ft. long) form a Latin cross and date from the 13th-14th centuries. Guido Bigarelli of Como worked (c. 1204) on the rich west front, with its portico of three arches surmounted by three ranges of open galleries and a Romanesque statue of St. Martin on horseback. In the nave, the *Tempietto del Volto Santo*, an octagonal shrine carved in 1482-84 by Matteo Civitali, contains an 11th-12th century wooden crucifix known as Christ's Sacred Countenance (legendarily begun by the disciple Nicodemus and later miraculously conveyed from the Holy Land to Italy). The cathedral contains other works by Civitali (1436-1501), a local sculptor who introduced Florentine styles to Lucca; and the tomb of Maria del Carretto (1408) by Jacopo della Quercia. The treasury houses fine goldsmiths' work, including the 14th-century Croce

dei Pisani made in Pisa. Other churches include S. Frediano, rebuilt in 1112-47 but retaining traces of an 8th-century structure, and having a nave, two aisles with side chapels, and a fine façade with a much-restored mosaic in the Byzantine style; the Romanesque S. Alessandro, reconstructed in the 12th century; the 12th-century S. Giovanni; S. Michele, with a marble interior and a 12th-13th century façade; Sta. Maria Forisportam, begun in the 13th century; the Gothic S. Francesco, with the tomb of Castruccio Castracani (d. 1328); and S. Romano, rebuilt by Vincenzo Buonamici in the 17th century.

Many paintings are preserved, especially in the Pinacoteca Nazionale, the Palazzo Mansi and the Museo Nazionale di Villa Guinigi. The home of composers Luigi Boccherini (1743-1805) and Giacomo Puccini (1858-1924), Lucca was for long an important musical centre. The public library, the state archives (in the Palazzo Guidiccioni), and the archiepiscopal library and archives contain many old and valuable books and documents.

A road and rail centre, Lucca is the market town of a rich agricultural region which exports high-quality olive oil. Silk has been manufactured since about the end of the 11th century. Other industries include flour milling and the manufacture of tobacco, paper textiles, jute goods and wine. The Serchio is used for water power, and an aqueduct (1823-32) with 459 arches carries the water supply from the Pisan mountains.

LUCCA PROVINCE (area 684 sq.mi.; pop. [1961] 360,605) contains the fertile Serchio plain in the south, the Apuan Alps in the northwest and in the north the Garfagnana valley, beyond which it reaches the Apennine crest. Principal towns besides Lucca are Viareggio (q.v.; a seaside resort), Castelnuovo, Pietrasanta, and Bagni di Lucca, 13 mi. N.N.E. of Lucca, where there are thermal mineral springs. In addition to the growing of olives, vines, fruit and cereals, there is marble quarrying in the Apuan Alps.

(A. T. L.)

History.—If the accepted text is right, the Roman historian Livy mentions Luca in a passage referring to the year 218 B.C. (book xxi, ch. 59); but Luca in this text may be a misreading for Luna. The town was situated in Ligurian territory; the Romans probably established a Latin colony there in 180 B.C. (Livy, xl, 43), which became a *municipium* during the Social Wars. A meeting place of roads to Parma, Florence and Rome (Via Clodia), Pisa and Luni, the town seems to have been fairly prosperous in antiquity. After A.D. 476, Lucca came under the rule of Odoacer and then of Theodoric, king of the Ostrogoths; in 553 its Gothic garrison put up a determined resistance against the Byzantines under Narses. Conquered by the Lombards from the Byzantines shortly after 568, Lucca became the residence of one of the three Lombard dukes in Tuscany. After Charlemagne's annexation of the Lombard kingdom (774), counts replaced the dukes, but the population appears to have remained largely Lombard.

Medieval Lucca.—Lucca greatly increased in importance during the 9th and 10th centuries, when its counts became margraves of Tuscany. Moreover, Lucca commanded the Via Francigena, which after the Lombard period was one of the principal roads between Lombardy and Rome and which assumed fresh significance after Otto I's coronation as Holy Roman emperor in 962. Under the margrave Hugh (d. 1001), Lucca's place in the march of Tuscany began to decline. Hugh lavished favours on Florence, which under the house of Canossa replaced Lucca as the capital of Tuscany.

Lucca was drawn into the Investiture conflict (see GERMANY: History; PAPACY) through its bishop Anselm, who became pope as Alexander II in 1061. Later the imperial party in the town prevailed, and the German king Henry IV rewarded the citizens in 1081 with a charter of liberties, mainly commercial. The commune of Lucca was probably established soon afterward, though consuls were not recorded until 1107 (see COMMUNE [MEDIEVAL]).

The conquest of the *contado* or countryside and wars with other cities followed the establishment of the commune. The 12th century was marked by recurring wars with Pisa. While Lucca desired free outlet to the sea, Pisa challenged Lucca's command of the Via Francigena. Thus when in 1181 a relatively lasting reconciliation was achieved, it was on the basis of a commercial agreement. The emperor Frederick I Barbarossa had confirmed Lucca's

communal liberties in 1162 but took the *contado* away in 1184, restoring only a small part of it in 1186; Lucca, however, recovered it after 1197. About that time, men with the office of *podestà* began to appear, replacing the consuls as the highest magistrates.

War with Pisa broke out again in 1218 and lasted intermittently until 1256; at the same time, Lucca had to face papal and imperial claims in the Garfagnana. The defeat of Pisa by Genoa in the battle of Meloria in 1284 strengthened Lucca's position in Tuscany, where the town was then second only to Florence. Economic prosperity came not only from a flourishing silk industry (Lucca's wool industry being already outstripped by Florence's), but also from a rapidly expanding banking business. It was assisted by the settlement of Luccese merchants in towns north of the Alps. The formation of guilds was followed, about 1250, by the political organization of the nonnoble population (*popolo*), which by the end of the century had taken control of the town. The statutes of 1308 show the government vested in the *anziani* (elders) and the "captain of the people," legislation being in the hands of the council of the people and the greater council.

During the emperor Henry VII's Italian expedition (1310-13), Guelph Lucca sided with Florence against him, while Pisa remained loyal to its Ghibelline traditions. In 1314, Pisa's new *signore*, Uguccione della Faggiuola, captured Lucca with the help of Luccese Ghibellines, among them Castruccio Castracani degli Antelminelli (*q.v.*). In 1316, however, Pisa and Lucca rose against Uguccione, and Castruccio was elected captain general of the people and "defender" of Lucca for 6 and then for 12 months—to be re-elected in 1317 for 10 years and in 1320 for life.

As the capital of Castruccio's powerful despotic state, Lucca became once more the leading city of Tuscany. But on Castruccio's death (1328) his state collapsed, and for Lucca there began a long period of troubles. Sold by the emperor Louis IV to Castruccio's uncle, the city was then sold by the German troops who had occupied it to the Genoese Gherardo Spinola. Spinola's rule (1329-31) was followed by that of John, king of Bohemia, who in 1333 sold it to the Rossi of Parma. Acquired in 1335 by Mastino della Scala of Verona, it was sold by him to Florence in 1341; but before the Florentines could take possession, the Pisans captured it in 1342. During the emperor Charles IV's visit to Lucca in Sept. 1368, Giovanni dell'Agnello, then *signore* of Pisa, fell from power, and Lucca finally regained independence, purchasing for 300,000 florins a charter of liberties from Charles in 1369. In 1370 reforms were passed which were codified in the statutes of 1372; the city was divided into *terzieri* (three units), and a gonfalonier of justice was placed at the head of the government of *anziani*.

The last decade of the 14th century was marked, in Tuscany, by the territorial expansion of Milan under Gian Galeazzo Visconti and, at Lucca, by the growing ascendancy of the Guinigi. After Lazzaro Guinigi's assassination in 1400 his brother Paolo was elected *signore* of Lucca with Gian Galeazzo's support. During the 30 years' rule of this rich merchant, Lucca prospered economically but suffered political setbacks. Florence was greatly strengthened by the acquisition of Pisa in 1406, and Lucca soon came under pressure. When in 1425 Florence decided to resist the renewed southward drive of Milan, Paolo remained loyal to Filippo Maria Visconti; and at the end of 1429 Florence declared war on Lucca. Francesco Sforza, formally dismissed from the Milanese service, came to Lucca's assistance, but turned against Paolo Guinigi, whom he sent a prisoner to Milan. Lucca resisted the Florentines successfully from 1430 to 1433, but, when the war flared up again in 1437-38, lost nearly all the *contado* to Florence. In 1441 a 50-year treaty was concluded between the two towns. Lucca recovered nearly all the lost lands and from then onward remained at peace with Florence. The Este family of Modena and the papacy, however, continued to claim Lucca's territory in the Garfagnana.

In the changed conditions of Italy after the French king Charles VIII's invasion (1494), Lucca succeeded in preserving independence from foreign rule. The emperor Charles V confirmed Lucca's privileges in 1522. The Medici restoration in Florence (1530) was considered by the Luccesi to be a threat to their own independence, as is shown in Francesco Burlamacchi's abortive scheme

in 1546 to liberate Pisa and march on Florence.

The Italian political situation contributed to Lucca's economic difficulties. The crisis of the silk industry led in 1532 to a ruthlessly suppressed rising of its workers. More lasting were troubles created by the spread of heretical doctrines: after an initial policy of relative toleration, repressive legislation was introduced in 1545, and persecution drove many people to emigrate. Yet Lucca continued to resist papal interference and refused to admit the papal Inquisition or the Jesuits—not, however, without serious clashes with the ecclesiastical authorities.

During the 16th and 17th centuries, the government became increasingly oligarchical. In 1556, under the gonfalonier Martino Bernardini, foreigners and their descendants were almost completely excluded from public office (*rimborso Martiniana*); and after 1628 only families that had been represented in such offices during the past 60 years and were listed in a *Golden Book* were qualified for them. The decline of trade and industry during this period shifted Lucca's economy to agriculture, with the ruling class becoming a landed aristocracy.

17th Century and After.—The long controversy with the Este over the Garfagnana, of which Lucca had retained only a few places, was finally submitted to the Milanese senate, which decided in 1618 against Lucca. Frontier controversies occasionally strained relations also with the Medici grand dukes of Tuscany. New walls, completed in 1645, were meant to protect Lucca against any eventuality.

The French Revolutionary Wars brought the creation of the Cisalpine Gaul Republic bordering on Lucca's territory (1797), so that Lucca had to toe the French line. In Feb. 1799 Gen. J. M. P. Sérurier entered the town and set up a government on the French model. When the French evacuated Lucca in July 1799, the Austrians ruled it until the French returned in July 1800. Under a democratic constitution introduced by Napoleon in Dec. 1801 Lucca recovered some measure of independence. The establishment of the French empire, however, put an end to the republic. In 1805 Napoleon created Felice Baciocchi, husband of his sister Elisa, hereditary prince of Lucca. Despite its disregard for local traditions and its financial disorders, the principate, under the effective rule of Elisa, brought considerable prosperity and reforms in law and administration, welfare and education, while its urbanistic policy changed the aspect of the town.

On the fall of Napoleon, Elisa fled (March 14, 1814). Occupied first by Joachim Murat's Neapolitan army (March-April), Lucca was taken in May 1814 by the Austrians, who occupied it until 1817. The congress of Vienna in June 1815 assigned Lucca, with the ducal title, to the Spanish infanta Maria Luisa, widow of the former King Louis of Etruria. Her son Charles, however, was heir to the Bourbon claims to Parma; and by the treaty of Paris of June 1817 it was agreed that the Bourbons of Lucca should succeed in Parma on the death of the archduchess Marie Louise, Napoleon's consort, in which event Lucca would pass to Tuscany. Maria Luisa restored ecclesiastical properties confiscated during the Napoleonic period, but in other respects continued the work of the principate. On her death in 1824 she was succeeded by her son Charles. The liberal movement was beginning to affect Lucca and the duke seemed at first to sympathize with it; but after 1840 his policy, under Austrian influence, dispelled such beliefs. Financial difficulties and increasing pressure from the liberals caused him on Oct. 4, 1847, to anticipate Marie Louise's death by ceding his duchy to Tuscany, with whose history that of Lucca is subsequently merged. (N. R.)

LUCE, CLARE BOOTHE (1903–), U.S. playwright and public official, was born in New York City on April 10, 1903. Privately educated in Garden City and Tarrytown, N.Y., she was associate editor of *Vogue* in 1930; associate editor and managing editor of *Vanity Fair* from 1930 to 1934. She was divorced from her first husband, George Tuttle Brokaw, in 1929, and she married Henry R. Luce (*q.v.*) in 1935. Mrs. Luce wrote a number of plays, including *The Women* (1936) and *Kiss the Boys Goodbye*

BY COURTESY OF T.M.E. INC.

(LEFT) HENRY R. LUCE AND (RIGHT) CLARE BOOTHE LUCE

(1938), satires on two phases of American life; and *Margin for Error* (1939), an anti-Fascist play. She also wrote the books *Stuffed Shirts* (1931) and *Europe in the Spring* (1940).

She was elected Republican congresswoman from Connecticut and served in the 78th and 79th congresses. In 1944 she was the keynote speaker in the Republican national convention that nominated Thomas E. Dewey for the presidency of the U.S., and in 1964 she made one of the seconding speeches for the nomination of Sen. Barry Goldwater. In February 1953 Pres. Dwight D. Eisenhower appointed her ambassador to Italy; she resigned in 1956 because of ill-health. In April 1959 she was appointed ambassador to Brazil by Pres. Eisenhower, but she resigned the following month.

LUCE, HENRY ROBINSON (1898-1967), U.S. magazine editor and publisher, was born in Tengchow, China, on April 3, 1898, son of Henry Winters Luce, a Presbyterian missionary. He was sent to the United States at 15 to attend Hotchkiss School, graduated from Yale in 1920, and later studied for a year at Oxford. After a brief reporting career on Chicago and Baltimore newspapers, Luce and a Yale classmate Briton Hadden founded the weekly news magazine *Time* in 1923 on an investment of \$86,000 and with 12,000 subscribers. Attracting attention by brightness, eccentricities of style, accent on personalities, and editorial orderliness, *Time* was an immediate success. Hadden died in 1929.

Heading *Time Inc.*, Luce founded *Fortune*, a monthly magazine of business, in 1930; *Life*, a weekly with its main emphasis on pictures, in 1936; and *Sports Illustrated*, a weekly, in 1954. The newsreel "March of Time" was produced from 1931 to 1953. *Time Inc.* purchased *Architectural Forum* in 1932, and 20 years later split from it *House & Home*. Publication of both *Architectural Forum* and *House & Home* was discontinued by *Time Inc.* in 1964: *Architectural Forum* was absorbed by *Fortune* and *House & Home* was sold to McGraw-Hill, Inc. In 1964 Luce retired as editor in chief of all *Time Inc.* publications and assumed the post of editorial chairman. Luce died in Phoenix, Ariz., on Feb. 28, 1967.

(F. L. Mr.; X.)

LUCE, STEPHEN BLEECKER (1827-1917), U.S. naval officer, first president of the Naval War College, was born in Albany, N.Y., March 25, 1827, and became a midshipman in October 1841. As a young officer he became interested in the training of seamen for the Navy and for the merchant marine; this interest developed into practical plans and methods for the improvement of naval education in general.

Luce is best known for the development of the Naval War College, at Newport, R.I., becoming the first president, Oct. 6, 1884. The U.S. Army and many foreign navies afterward copied this idea of higher professional education for officers. Luce was succeeded as head of the Naval War College by Alfred Thayer Mahan (q.v.). After his retirement, in 1889, he continued as a special adviser at the college until 1910. He died July 28, 1917. (J. B. Hn.)

LUCERA (anc. LUCERIA), a town and episcopal see in the Puglia region of Italy, province of Foggia, 20 km. (12½ mi.)

WNW of Foggia by rail, on a lofty plateau projecting west (highest point 823 ft.). Pop. (1961) 27,919 (commune).

The older part of the city is medieval in appearance, with small, narrow streets. The bastioned Swabian-Angevin castle on Monte Albano, on the site of the Roman citadel, dominates the scene. Among the many churches the oldest is S. Francesco (1301); the cathedral, built on the ruins of a mosque in the centre of the city, was restored in Gothic style after 1300. There are also a number of noteworthy 17th- and 18th-century palaces.

Lucera is particularly noted for the manufacture of building materials; there are extensive deposits of clay near the city. Other industries are milling, oil refining, wool and dairy products and furniture manufacture.

An Oscan city on the site was occupied by the Romans in the 4th century B.C.; subsequently it was given the rank of *colonia* and later raised to full citizenship. (For the history of the region in Roman times, see APULIA.) The city was destroyed in 663. In the 13th century it was refounded by the Holy Roman emperor Frederick II, who established there Saracen colonists, to whom he granted religious freedom, and built an imposing castle (of which ruins are still standing). Early in the 14th century the Saracens were killed or forcibly converted and the town was repopulated by Christians.

LUCERNE (Ger. LUZERN), capital of the central Swiss canton of the same name, is situated 1,430 ft. (436 m.) above sea level at the point of issue of the Reuss River from the northwestern branch of the Lake of Lucerne (Vierwaldstättersee), 60 mi. (96 km.) SE of Basel and 179 mi. (288 km.) NNW of Milan, Italy, by the St. Gotthard railway. Pop. (1960) 67,433. With its splendid lakeside gardens and promenades, its well-preserved town walls (Musegg), and its nine watchtowers, Lucerne enjoys one of the loveliest settings of any town in Switzerland. It is divided into two parts by the Reuss, which is crossed by five bridges within the town boundaries. Of these, the oldest are two roofed bridges: the zigzag Kapellbrücke (completed 1333), adjoining the still older Wasserturm (water tower) and spanning the Reuss at an angle; and the Spreuerbrücke (1407). Both bridges have decorated panels painted in the early 17th century. The main bridge is the Seebücke, joining the Bahnhofplatz (Station Square) on the left bank and the Schwanenplatz (Swan Square) on the right bank.

JAMES P. BARRY. PIX FROM PUBLIX

THE 14TH-CENTURY KAPPELLBRÜCKE (CHAPEL BRIDGE) SPANNING THE REUSS RIVER, LUCERNE, WITH THE WASSERTURM (WATER TOWER) ON THE LEFT

On the left bank are the railway station (1897), central post office (1888), telephone and telegraph office (1952), municipal theatre (1839), cantonal government building, or Ritter Palace (Rittersche Palast, 1557-64; from 1577 to 1804 a Jesuit college), state archive (1729-31) with its rococo Marian chamber, central library (housing since 1951 the cantonal and municipal libraries, numismatic collection, natural history museum, and Helvetica collection), the St. Francis Xavier (Jesuit) Church (1666-77) with Baroque vestry, the 14th-century Gothic Franciscan church with rococo transepts, the corporation building (1675), new town hall (1913), Richard Wagner Museum (opened 1933), and the modern St. Anthony's Church (1954). On the right bank, the old town, bounded on the north by the 14th-century Musegg wall, is distinguished by picturesque alleys and squares with medieval houses, while the more recent quarters (built since 1850) are strung out loosely along the hillside. Among the many noteworthy buildings are the early 17th-century Rathaus (the old town hall), housing the historical museum, Am Rhyn House (1617), St. Peter's Chapel (1178), the Hofkirche (cathedral and collegiate church of St. Leodegar [1639]) with choristers' houses, a Tuscan cemetery, and two slender towers (1504), and the Mariahilf Church (1676-81). Interesting sights are the Lion Monument, hewn from the sandstone rocks in 1819-21 by Lucas Ahorn from the model by Bertel Thorvaldsen, in memory of the Swiss guards slain while defending the Tuileries in Paris in 1792; the Glacier Garden (Gletschergarten), with excavations of 1872-75 and a large relief map of central Switzerland (1766-85); the comprehensive Swiss transport museum (1959); and the Utenberg folk costume museum.

In addition to various cantonal and municipal institutions of higher education there are the central Swiss transport school, the Swiss Catholic school of sacred music, the central Swiss technical college, and the Swiss schools of bakery and of hotel keeping. Lucerne is also the seat of the supreme cantonal court, a commercial tribunal, a criminal court, juvenile court, and the federal insurance court.

Because of its magnificent surroundings, sunny climate, and easy access by road and rail from all directions, Lucerne has become an important centre of Swiss tourism. Steamer services on the lake connect with various mountain railways and cableways, e.g., to Pilatus, Rigi, Bürgenstock, and the Stanserhorn, and there is a direct narrow-gauge rail connection with the winter sports centre of Engelberg. Tourist facilities and attractions include a casino, bathing beaches, rowing and sailing regattas, horse-racing and show-jumping competitions, an international festival of music, and a traditional pre-Lenten carnival. The town's commercial and industrial activity depends largely on the tourist trade.

Lucerne derived its name from the Benedictine monastery of Luceria, founded in the 8th century near the site of the Hofkirche and later a cell of Murbach monastery in Alsace. From the nearby fishing village grew a town, whose inhabitants were originally serfs of the monastery. After the opening of the St. Gotthard Pass (c. 1220) Lucerne rapidly gained importance. As early as 1252 the citizens drew up the first municipal constitution. In 1291 the monastery and town were purchased by the German king Rudolf I of Habsburg, against the will of the citizens, who were struggling for independence. The political instability under Rudolf's successors led in 1332 to alliance with the three cantons of Uri, Schwyz, and Unterwalden, which had already joined forces in 1291, and after the battle of Sempach (1386) against the Habsburg army the alliance won its freedom and independence. By 1415 the town had acquired almost all the territory belonging to the present canton, either by treaty, armed occupation or purchase. At the Reformation Lucerne assumed the leadership of the Catholic cantons, and was the seat of the papal nuncio from 1581 to 1848. In the peasant revolt of 1653 the Lucerne area was one of the centres of opposition to the aristocratic regimes of the towns, the members of which had acquired wealth and power by mercenary service in foreign armies and pensions granted by foreign princes. In 1798 the patricians were compelled to abdicate under the onslaught of the Napoleonic armies.

Lucerne was for a time the capital of the Helvetic Republic and finally, in 1803, by the Act of Mediation, it resumed its original

status as an independent canton. In 1814 the aristocratic regime was restored, being replaced between 1831 and 1841 by a Liberal government. Then power was assumed by a Radical-Conservative Catholic faction which pursued a separatist policy directed against the liberal cantons, leading in 1847 to the Sonderbund War and Lucerne's defeat by federal troops. In 1848 Lucerne again entered the Swiss Confederation as a full member and was granted a liberal constitution, which was later replaced by a conservative one. Under the latter system the transition from representative to direct democracy was effected. By the mid-1960s Conservative governments had been in power since 1871, although usually with a small majority.

LUCERNE CANTON is the third largest canton in the Swiss Confederation. Area 577 sq.mi. (1,494 sq.km.). Pop. (1960) 253,446, mainly German-speaking. It is divided into five administrative districts (Lucerne, Sursee, Hochdorf, Entlebuch, Willisau). Of the total surface area 91% is productive land. The main sources of income are field crops, fruit growing, cattle rearing, industry, and tourism. Industrial products include textiles, machinery, metallurgical goods, paper, wood, tobacco, electrical equipment, stone, glass, and ceramics; there is also shipbuilding and automobile assembly. A busy transit traffic between West Germany and Italy crosses the canton. The highest points are the Brienzer Rothorn (7,720 ft. [2,353 m.]), the Tannhorn (7,296 ft. [2,224 m.]), and Pilatus (6,965 ft. [2,123 m.]).

The Constitution of 1874 defines the canton as a democratic free state within the Swiss Confederation. The legislature (*Grossrat*) consists of 170 members, at least 20 years of age, who are elected by direct male vote for a term of four years. The executive consists of seven members, similarly elected for a term of four years. Its president (the *Schultheiss*) and his deputy (the *Statthalter*) are appointed by the *Grossrat* for a one-year term. Each district is supervised by a government representative (*Regierungsstatthalter*) and has a district court.

LUCERNE: see ALPILFA.

LUCERNE, LAKE OF, the name usually given by English-speaking people to the principal lake of central Switzerland. In French it is called the *Lac des Quatre Cantons*, and in German the *Vierwaldstättersee*, the cantons being Lucerne, Unterwalden, Uri and Schwyz. It is named after Lucerne, at the western end, where the Reuss leaves the lake, having entered it near Flüelen at the southeastern end; the Muota flows into the lake at Brunnen (north) and two mountain streams, the Engelberger and the Sarner Aa enter at Buochs (south) and Alpnachstad, respectively. The lake is most beautifully situated between steep limestone mountains, the best known being the Rigi (north) and Pilatus (south-west), and great promontories such as Horw (west), Bürgenstock (south), Meggenhorn (north) and Seelisberg (south) project into its waters, giving the city of Lucerne a romantic setting. The lake occupies the site of converging piedmont glaciers and along its shores moraines dam back its waters.

The area of the lake is about 114 sq.km. (44½ sq.mi.); it is about 39 km. (24 mi.) long, its greatest width only 3 km. (2 mi.) and its greatest depth 702 ft., while the surface of the water is 1,424 ft. above sea level. The lake is composed of four main basins (with two side basins), which represent four glaciated valleys, topographically distinct, and connected only by narrow and tortuous channels. There is, first, the most easterly basin, the lake of Uri, extending from Flüelen (south) to Brunnen (north). At Brunnen the delta of the Muota extends into the lake where it turns west, so that it forms the lake of Gersau, or of Buochs, from the promontory of Seelisberg (east) to that of Bürgenstock (west). Another narrow passage between the two "Noses" (*Nasen*) leads west to the basin of Weggis, between the Rigi (north) and the Bürgenstock promontory (south). This expanse forms the eastern arm of the "Cross of Lucerne," the western arm being the lake of Lucerne, the northern arm the lake of Küssnacht and the southern arm that of Hergiswil, prolonged southwestward by the Alpnach lake, with which it is joined by a narrow channel, spanned by the Acher iron bridge. The lake of Uri provides the most forbidding scenery; at Brunnen the Everlasting League of 1315 was formed while the legendary place of meeting of the

founders of Swiss freedom was the meadow of the Rütli (purchased by the confederation in 1859). The site of William Tell's leap from the boat in which the bailiff Gessler was taking him to prison is marked by the Chapel of Tell (east).

In the lake of Gersau is the village of Gersau (north), an independent republic from 1390 to 1798, and now in Schwyz (1818 onward). In the next basin to the west is Weggis (north), and on the northern shore of the lake is Vitznau, whence a rack railway leads to the top of the Rigi (4½ mi.) while on the southern shore of the lake is Kehrsiten, with an electric railway to the Bürgenstock promontory. Lucerne and Flüelen are connected via Arth-Goldau by the St. Gotthard railway. On the promontory between Lucerne and Küsnacht stands the castle of New Habsburg, while from Küsnacht a motor road leads through the "Hollow Way" (*Hohle Gasse*), the scene of the legendary murder of Gessler by William Tell. The western shore of the southern arm is traversed from Horw to Alpnachstad by the Brünig railway (5½ mi.), which continues toward Sarnen (Obwalden) and the Bernese Oberland, and southwest from Alpnachstad, whence a rack railway leads northwest up Pilatus (2½ mi.).

Lucerne is a tourist centre of importance, but several settlements serve as lake ports for neighbouring villages (Brunnen for Schwyz, Flüelen for Altdorf, Stansstad for Stans, Alpnachstad for Sarnen). Most of the villages are summer resorts (Gersau also in winter), especially Hertenstein, Weggis, Gersau, Brunnen, Beckenried and Hergiswil, while hotels have been built on eminences, as well as on the Rigi, Pilatus and the Stanserhorn. (A. F. A. M.)

LUCHAIRE, ACHILLE (1846–1908), French historian, whose original work on the Capetians had great value, was born in Paris on Oct. 24, 1846, and died there on Nov. 4, 1908. In 1879 he became a professor at Bordeaux and in 1889 professor of medieval history at the Sorbonne; in 1895 he became a member of the Académie des Sciences Morales et Politiques. The most important of Achille Luchaire's works are *Histoire des institutions monarchiques de la France sous les premiers Capétiens* (1883 and again 1891); *Manuel des institutions françaises: période des Capétiens directs* (1892); *Louis VI le Gros, annales de sa vie et de son règne* (1890); *Étude sur les actes de Louis VII* (1885); *Innocent III* (6 vol., 1904–08); and contributions on the 13th century to E. Lavisse' great history of France.

LU CHIU-YÜAN, better known under his literary name, LU HSIANG-SHAN (1139–1193), Chinese idealist philosopher and rival of his contemporary the Neo-Confucian rationalist Chu Hsi. Lu's doctrine of mind culminated three centuries later in the philosophy of Wang Yang-ming (Wang Shou-jen; q.v.), whose main tenets show the direct influence of Lu. Together the two philosophers have been called the Idealistic School of Lu-Wang, as opposed to the Realistic School of Ch'eng-Chu, named for Ch'eng I (Ch'eng I-ch'uan) and Chu Hsi. Both schools still attract adherents today.

Lu was born in modern Kiangsi Province, the youngest of six brothers. He was educated partly by his father, held a number of government posts, and taught at the Imperial Academy for several years. The long-standing philosophical differences between Lu and Chu Hsi began with an encounter at Goose Lake Temple in northern Kiangsi in 1175. Lu, as a cosmic monist, held that there is one and only one world, as opposed to Chu's dualist position (for Chu's philosophy, see CHU HSI). For Lu, the world is monistic, and all of its phenomena are to be found within one's own mind (*hsin*): "The universe is my mind and my mind is the universe"; i.e., the universe and mind are identical. Lu's central concept is mind, which he conceives: (1) metaphysically as objective, universal, all-comprehending, identified with principle (*li*, the pattern of organization of the universe; see CONFUCIANISM: *Neo-Confucianism*), and understandable to each individual mind; and (2) ethically as subjective, identifying it with human nature (*hsing*), which, following the view of Mencius (q.v.), Lu held to be originally good. This idealistic position led Lu—in contrast to Chu, whose method of achieving moral excellence was by "constant inquiry and study" (*tao wen hsieh*)—to propound his own method of "honouring the virtuous nature" (*tsun te hsing*). Hence, the aim of Lu's education (in contrast to Chu's emphasis

on studying external things) is to teach man to live in accord with the universal mind and to seek an understanding of the principles lying within himself. The highest knowledge of the Way (*tao*) comes to man from his constant practice of inner reflection and self-culture, which is the best way to develop completely one's original goodness, or to regain it if it has been corrupted and lost by material desires (*wu yü*).

Lu devoted most of his life to teaching and lecturing. He was not a systematic writer, his disinterest being expressed in the statement "The Six Classics will all serve as my commentaries." After his death, his literary works were published under the title of *Hsiang-shan Hsien-sheng Ch'üan-chi* ("Complete Works of Lu Hsiang-shan"). In 1217 he was canonized as Wen-an, and in 1530 a tablet in his honour was placed in the Confucian temple.

LUCHU ISLANDS: see RYÜKYÜ ISLANDS.

LUCIAN, SAINT, OF ANTIOCH (LUCIAN THE MARTYR) (d. 312), Christian theologian and martyr, was born at Samosata (modern Samsat, in southern Turkey). His parents, who were Christians, died when he was 12. In his youth he studied under Macarius of Edessa, and after receiving baptism he adopted a strictly ascetic life. Settling at Antioch he became a presbyter, and is regarded as the founder of the theological school of Antioch. Though he is represented as the connecting link between the heretics Paul of Samosata and Arius (q.v.), he was in good standing at the outbreak of persecution, and the reputation won by his high character and learning was confirmed by his courageous martyrdom.

Lucian was carried to Nicomedia before the emperor Maximinus, and persisting in his faith perished on Jan. 7, 312, under torture and hunger, which he refused to satisfy with food offered to idols. His defense is preserved by Rufinus (ix, 6) and Eusebius (*Church History*, ix, 9). His remains were conveyed to Drepanum in Bithynia, and under Constantine the town was founded anew in his honour and exempted from taxes (A.D. 327). There in 387, on the anniversary of his death, Chrysostom delivered the panegyric homily from which the facts given above are mainly derived.

Jerome says that Lucian wrote *Libelli de fide* and several letters, but only a short fragment of one epistle remains. The authorship of a confession of faith ascribed to Lucian and put forth at the semi-Arian synod of Antioch (A.D. 341) is uncertain. Lucian's most important literary labour was his edition of the Greek Old Testament corrected by the Hebrew text. From his work derives the text commonly used until modern times, probably for the New Testament as well. St. Lucian's feast day is Jan. 7.

Swete (ed.), *An Introduction to the Old Testament in Greek*, pp. 80–85 (1900). (E. R. Hy.)

LUCIAN (c. A.D. 125–c. 190), a satirist notable for his wit and the elegance of his Greek, was born at Samosata in Syria (now Samsat in Turkey). The only reliable information as to the dates and facts of his life comes from what he himself says in his writings. According to the *Enhyphion* ("Dream"), his parents, who were of limited means, apprenticed him to an uncle who was

a sculptor, but he soon abandoned sculpture for rhetoric. He spent the next few years in Ionia perfecting his Greek, becoming thoroughly familiar with the classical authors, particularly with Homer, Plato and the comic poets, and studying rhetoric. He then adopted the profession of a rhetorician, and in this capacity traveled widely, visiting Greece and Italy, and winning particular success in Gaul. On a visit to Rome, perhaps when about 25 years old, he made the acquaintance of the Academic philosopher whom he praises in his *Nigrinus*. At the age of about 40 he abandoned rhetoric for dialogue; thereafter Athens became his permanent home. When old and infirm he accepted a post in Egypt in the service of the emperor (perhaps Commodus). This post he describes as important, well-paid and involving clerical duties mainly for the courts. He outlived the death of Marcus Aurelius, but the date and circumstances of his death are unknown.

Of the 80 prose works attributed to Lucian about 10, including the *Onos* ("Ass"), are generally regarded as spurious. Rhetorical works such as the *Myias encomion* ("Praise of the Fly") probably belong to his earlier years; despite his unhappy apprenticeship he retained enough interest in art to produce several *ekphrasises* (i.e., descriptions of works of art). He used many prose forms but is most famous for his dialogues, among the best of which are the *Symposion* ("Banquet"), *Charon, Halieus* ("Fisher"), *Bion Prasis* ("Sale of the Lives"), *Timon* and *Dis katorgoumenos* ("Twice Accused"), and the four collections of minor dialogues, *Hetairikoï dialogoi*, *Nekrikoï dialogoi*, *Theon dialogoi* and *Enalioi dialogoi* ("Dialogues of the Courtesans," "Dialogues of the Dead," "Dialogues of the Gods," "Dialogues of the Sea-Gods"). Verse works doubtfully attributed to Lucian are some epigrams and two mock tragedies on gout.

Satire.—Just as Juvenal claims all human activity for his sphere, so too Lucian satirizes every aspect of human behaviour. A favourite topic is man's failure to realize the transiency of greatness and wealth. This Cynic theme permeates the *Charon* (in which Charon and Hermes pile mountain upon mountain to look down upon the vanities of this world), while, in the "Dialogues of the Dead" and elsewhere Menippus the Cynic is made to jibe at kings and grandees, reminding them how much more they have lost by death than he. The *Timon* recounts how Timon, after impoverishing himself by his generosity and becoming a hermit, is restored to wealth, once again to be surrounded by toadies to whom he gives a short shrift. Other human frailties satirized are the folly of bargaining with the gods by sacrifices (*Peri thysion*) or crying over spilt milk when bereaved (*Peri penthous*) or the love of telling or listening to strange tales (*Philopseudes*), while the *Alethes historia* ("True History," which starts by warning the reader that its events are completely untrue and impossible, and describes a voyage that starts on the sea but continues in the skies and includes visits to the belly of a whale and to the Elysian fields) is also directed against human credulity. In the *Nigrinus* Lucian makes an Academic censure the evils of Rome, contrasting the pretentiousness, lack of culture, avarice and will-hunting of Rome with the quiet cultured life of the Athenians.

Lucian in the "Fisher" gives himself the pseudonym *Parrhesiades* (Mr. Frank) and is particularly outspoken against those whom he considers impostors. In the *Alexandros* Lucian attacks Alexander the Paphlagonian and gives his account of the various hoaxes by which Alexander was amassing wealth as a priest of Aesculapius (Asclepius) and a seer; Lucian tells how instead of greeting Alexander by kissing his hand he bit it and how Alexander in revenge plotted unsuccessfully to have him drowned at sea. Another dubbed by Lucian as an impostor was the Cynic Peregrinus who burned himself on a pyre at the Olympic games. The *Peregrinus* is particularly interesting for its reference to the Christians. According to Lucian Peregrinus had once been imprisoned for Christian activities, and while in prison had been enriched by contributions from the Christians, but on his release renounced Christianity. Lucian comments thus on the Christians: "The poor wretches have convinced themselves that they will be completely immortal and live for ever; therefore they despise death and in most cases willingly surrender themselves. Furthermore their first lawgiver has persuaded them that they are brothers of each

other once they have renounced the Greek gods and worship that crucified teacher (*sophistes*) and live by his laws. Therefore they despise everything alike and believe in communism of property." In several other places also Lucian castigates credulity in religious matters.

Attitude to Philosophy.—To Lucian the worst charlatans of all were the philosophers who failed to practise what they preached. The "Banquet" gives an amusing account of an imaginary wedding feast given by a patron of the arts. Among the guests are representatives of every philosophical school who all behave outrageously; indeed, when the party is breaking up, they start fighting over delicacies to take home till the scene resembles the fight of the Centaurs and Lapithae. Hypocritical philosophers are also attacked in the "Fisher," in which the founders of the philosophical schools return to life to indict Lucian for writing the "Sale of the Lives" (a lighthearted work in which Zeno, Epicurus and others are auctioned by Hermes in the underworld but fetch next to nothing). Lucian's defense is that he was attacking not the founders of the schools but their present unworthy successors. The philosophers acquit Lucian and call to trial their modern disciples who refuse to have their lives examined till Lucian fishes for them from the Acropolis using a bait of gold and figs. He soon has a fine catch of philosophers who are renounced by the founders of the schools and hurled to their deaths from the Acropolis.

Lucian follows the lead of Xenophanes, Plato and others in complaining about the absurd beliefs concerning the Olympian gods. Thus the discreditable affairs of Zeus with mortal women play a prominent part in the "Dialogues of the Gods." Moreover Lucian seizes on Homer's admission that Zeus is subject to Fate. In *Zeus elenchomenos* ("Zeus Cross-Examined") a Cynic tells Zeus that he is powerless to interfere on earth. In *Zeus Tragodos* ("Zeus Rants") Zeus is panic-stricken because a Stoic is losing an argument on earth with an Epicurean who maintains that the gods neither exist nor exercise providence. Momus ("Blame"), one of the interlocutors, suggests certain defeat for the Stoic because so many evil men prosper and so many good men suffer undeservedly, but Zeus is prevented by Fate from using his thunderbolt against the Epicurean. In the end the Stoic, having failed with every other weapon, is forced to use his fists.

Lucian's interest in philosophy is superficial, and none of his dialogues is really philosophical except perhaps *Anacharsis* ("Gymnastics") and *Hermotimus*, an exposition of the futility of the Stoic discipline. Lucian acknowledges allegiance to no particular school, criticizing the representatives of all philosophies. He has most sympathy with the Epicureans for their insistence that the gods do not interfere on earth; many dialogues lay a Cynic stress on the impermanence of prosperity, partly perhaps because of his literary models, but he parts company with Cynicism when it becomes sensational (e.g., *Peregrinus*) or offends the decencies. His most bitter criticisms are directed against the Stoics particularly for their simultaneous belief in Fate and in divine providence. He does praise two philosophers, Demonax the Cynic, and the Academic of the *Nigrinus*, but presumably for their conduct rather than their theories. His attitude to philosophical studies is best seen in the "Banquet" ch. 34, where, after noting how much worse the philosophers are behaving than the ordinary guests, he comments that he cannot help reflecting that book learning is worthless if it does not improve one's conduct.

Literary Criticism.—Lucian's best work in this field is his treatise on how to write history (*Pos dei historian syngraphēn*). He defines the ideal historian as one who is "fearless and incorruptible, independent, a lover of frankness and truth, one who calls a spade a spade, unsparing and un pitying, an impartial judge, benevolent toward both sides, but giving neither more than its due, in his writings a stranger without a city, bowing to no authority and acknowledging no king, not considering what this man or that will think but stating facts as they occurred." There are also admirable remarks on the ideal historical style and amusing descriptions of contemporary historians who ape Thucydides by introducing plagues and funeral orations. Less attractive are the attacks on contemporary rhetoricians. The *Rhetoron didaskalos*

("Teacher of Orators"), containing ironical advice on how to become a successful orator by means of claptrap and impudence, may be directed against Pollux, the lexicographer, while the *Lexiphanes* ("Word-Flaunter") attacks a contemporary who is excessively fond of archaic and recondite vocabulary.

In ch. 33 of the "Twice Accused" (where Lucian is indicted by Rhetoric for deserting her and by Dialogue for taking away his dignity by the introduction of comic elements) Lucian says he has added to dialogue "jest and lampoon and Cynicism and Eupolis and Aristophanes, and lastly Menippus, a truly formidable Dog (i.e., Cynic) who laughed while he bit." If in style Lucian owes much to Plato, he finds ideas for his plots in many writers, particularly Homer, Aristophanes and, no doubt, the lost works of Menippus; but judging from the *Timon*, which is Cynic in tone but influenced by the *Plutus* of Aristophanes, Lucian adapted and blended his literary antecedents in an original way. Menippus may have given Lucian his Cynic viewpoint; Menippean works such as the "Banquet" and the "Sale of Diogenes" may have suggested ideas for the "Banquet" and the "Sale of the Lives"; but, as Lucian in his *Prometheus ei en logois* ("Literary Prometheus") denies any plagiarism on his part, most authorities believe that he did not copy Menippus particularly closely. Moreover the term Menippean satire, as denoting a mixture of prose and verse, can be applied to very few of Lucian's works. Lucian says in the same work that he seeks to be praised not for originality but for perfection and for achieving a harmonious blend of dialogue and comedy, and, strictly speaking, he cannot be called the founder of satirical dialogue in view of the prior claims of Menippus and indeed the satiric elements in Plato (e.g., *Euthydemus*); his merit lies in his initiative in resuscitating and improving the genre used by Menippus, and, as he claims ("Twice Accused" ch. 34), making dialogue more attractive.

Lucian may have known some Latin, but despite some similarities of theme it cannot be proved that he was influenced by Roman satire. Lucian and Varro had a common source available in Menippus. If Juvenal's third satire and the *Nigrinus* both attack the evils of Rome and Juvenal's tenth satire like the *Ploion* ("Ship") deals with the vanity of human wishes, such natural topics for satire may well have been suggested to both writers by their observation of life or by their reading (e.g., of Cynic diatribes) or by both. Tatian and other Christian apologists attack the amours of the gods in much the same way as Lucian, but there is little evidence that they knew Lucian or he them. Because Lucian feels bound to amuse as well as to instruct his audience, his satire usually lacks the ferocity of Juvenal and his touch is even lighter than that of Horace; on such occasions his subjects may have been suggested partly by his reading, and his satire may often apply to the whole classical era as much as to the Antonine age; occasionally he attacks contemporaries such as Peregrinus, the "Teacher of Orators" or the "Ignorant Buyer of Books" with the venom of an Archilochus.

Influence.—Ever since the Renaissance Lucian has had a considerable influence on many European writers including Erasmus, Rabelais and Voltaire, and on artists such as Botticelli, who painted "Calumny" from Lucian's description in *Peri tou me rhadios pisteuein diabolē* ("Slander") of a painting by Apelles. The *editio princeps* appeared at Florence in 1496. The English writer who perhaps has most in common with Lucian is Jonathan Swift, who may well have taken ideas for *Gulliver's Travels* from the "True History." Lucian's influence on posterity, his thorough assimilation of the spirit of classical Greece, his novel use of his literary antecedents, his wit, the ease and lucidity of his style (founded on the best Attic models and only in a few minute details aberrant from them) entitle him despite his date to be ranked among the great names in classical literature.

LUCIDOR, LASSE, pseudonym of LARS JOHANSSON (1638-1674), Swedish lyric poet, author of some of the most powerful poems of the baroque period in Swedish literature, was born in Stockholm in 1638. Lasse studied at Greifswald and Leipzig, and spent several years abroad as a wandering scholar and, perhaps, actor. On returning to Sweden, he lived first in Uppsala and, after 1669, in Stockholm, becoming known as a writer of funeral elegies and epithalamiums. His most personal poems are drinking songs and funeral hymns—a typically baroque combination. His models were the German baroque poets, among them Andreas Gryphius, but his best poems surpass theirs in intensity of feeling and power of expression. His most famous song, "Skulle Jag sörja så vore Jag tokot" ("Were I to grieve, then I were a fool"), was written in prison, after an accusation of using disparaging words in a poem to a noble family. He was killed in a tavern brawl in Stockholm, Aug. 13, 1674.

Lucidor's poetry was posthumously published in *Helicon Blomster* (1689). His *Samlade Dikter* were edited by F. Sandwall in a commented edition (1914-30). (CL. FN.)

LUCIFER (d. 370/371), bishop of Cagliari in Sardinia, was a supporter of Athanasius (q.v.) and the founder of a small rigorist sect named after him. Nothing is known of his life until after the Arianizing Council of Arles in 353, when he tried to obtain a new and impartial council. At the Council of Milan (355) he refused to sign the condemnation of Athanasius, and was exiled to the east, where he wrote five polemical tracts remarkable more for their violent language against Constantius II than for correctness and wealth of doctrine. His quotations from scripture, however, are of value for the study of the Old Latin text. Of his letters, two survive.

Allowed by Julian's edict to return home, Lucifer declined an invitation to attend the synod of Alexandria (362), and passed through Antioch, where he refused to recognize Meletius as bishop, and consecrated Paulinus, leader of the Eustathian faction, in his stead, thus prolonging the Antiochene schism for many years (see MELETIUS, SAINT, of Antioch). Lucifer refused ecclesiastical fellowship with all those who had signed, even under duress, the Arianizing formula of Rimini (359), as he considered them fallen from their clerical dignity through heresy. The short-lived sect which he founded comprised small groups in Spain, Gaul and even Rome.

LUCIFER (Greek *Phosphoros*, "lightbearer"), the morning star; i.e., the planet Venus at dawn. Personified as a male figure bearing a torch, Lucifer has almost no legend, but in poetry is often herald of the dawn. St. Jerome translated as "Lucifer" the metaphorical reference (Hebrew, "shining one") to the fall of the king of Babylon in Isa. xiv, 12. The Church Fathers interpreted the words of Jesus in Luke x, 18, "I saw Satan fall like lightning from heaven," as a reference to this passage in Isaiah, so that "Lucifer" came to be regarded as the name of Satan before his fall. It is so used by Milton in *Paradise Lost*, and the idea underlies the proverbial phrase "as proud as Lucifer."

(H. W. PA.)

LUCILIUS, GAIUS (c. 180-c. 102 or 101 B.C.), the earliest Latin satirist, of whose writings only fragments remain, was born at Suessa Aurunca, on the Campanian confines of Latium. He was of good family and education, and served under Scipio Aemilianus in the Numantine War in Spain, 134-133 B.C. He was a friend of learned Greeks and well acquainted with Greek manners and thought, was on intimate terms with Scipio and mixed with other great figures of his time. He spent the greater part of his life at Rome but was living at Naples when he died. His career as a writer extended from 131 B.C. to nearly the end of his life. His works were collected in a posthumous edition of 30 books, of which the last five were the earliest in date. In his four earliest

books Lucilius composed in *septenarii* and *senarii*, as well as in hexameters. After his fourth book, he chose the hexameter except for some poems in elegiacs. Of his work about 1,300 complete or partial lines have survived.

Lucilius may be regarded as the inventor of poetical satire, as he was the first to give to the formless Latin *satura* that distinctive character of critical comment on manners, politics and literature which the word "satire" still denotes. Unlike other forms of Latin literature, it owes virtually nothing to Greek. In his style and his choice of subject Lucilius was equally original. He ridiculed the conventional language of epic and tragic poetry and used the style of familiar speech, even to the point of frequently employing Greek, which was then fashionable in educated circles. For his subjects he abandoned the hackneyed ground of Greek and Roman mythology and treated of the politics and wars, the business and pleasure, the scandals and vices of his own day. These he handled, not in Juvenal's spirit, but, like Horace, from the standpoint of a man of the world and the associate of men of affairs. But he differed from Horace in being a thoroughly good hater, and also in a savage outspokenness of attack characteristic of the public life of his age.

Lucilius' unpolished and vigorous poetry was something new. Its topics were various: politics, social life, luxury, marriage, aims in writing, history, literary and dramatic criticism, grammar, rules of spelling, a letter to a friend, a journey. But it was largely self-portraiture, and this is borne out by Horace, whose artistic development in his hexameter writings owed much to Lucilius' work. Lucilius is recorded as saying that he wrote neither for the most ignorant nor for the most learned. Quintilian says that some men of his day preferred Lucilius not only to all other satirists but to all other poets. Certainly the loss of his work, except for fragments, is one of the most grievous in Latin literature.

Warmington, *Remains of Old Latin*, with Eng. trans., vol. iii "Loeb Series" (1938). See also G. C. Fiske, *Lucilius and Horace* (1920); C. Cichorius, *Untersuchungen zu Lucilius* (1908); N. Terzaghi, *Lucilio* (1934); Pauly-Wissowa, *Real-Encyclopädie der klassischen Altertumswissenschaft*, vol. xiii (1927). (G. B. A. F.)

LUCINA, "light bringing," an epithet applied to both Diana and Juno (*qq.v.*) but particularly to the latter as protectress of women, especially in childbirth. As a goddess especially of moonlight, and hence controller of the menses, Lucina's functions spread over the entire birth cycle: fertility, conception, pregnancy, nourishment of the fetus, labour and delivery, lactation, etc. On coins Juno Lucina is represented as a matron holding a child and a flower, symbols of fertility. A shrine of Juno Lucina on the Cispinus dated from 375 B.C., and the introduction of the cult went back traditionally to Titus Tatius.

See G. Wissowa, *Religion und Kultus*, 2nd ed., p. 183 ff. (1912); S. B. Platner, *Topographical Dictionary of Ancient Rome*, completed and rev. by Thomas Ashby, s.v. "Juno Lucina" (1929).

(R. B. LD.)

LUCIUS, the name of three popes.

SAINT LUCIUS I (d. 254), pope from 253 to 254, succeeded Cornelius in the summer of 253. Exiled at first, he returned to Rome at the accession of Valerian and received a letter of congratulation from St. Cyprian. Cyprian, writing later to Pope Stephen I, referred to Cornelius and Lucius as being in agreement with Cyprian's policies. St. Lucius died in March 254. His feast day is March 4.

(F. X. G.)

LUCIUS II (Gherardo Caccianemici) (d. 1145), pope from 1144 to 1145, was born at Bologna, was cardinal and papal chancellor and succeeded Celestine II on March 12, 1144, the year the Romans proclaimed a constitutional republic, rejecting papal civil rule. Lucius made a truce with King Roger II of Sicily and recognized Portugal as a papal fief. He died on Feb. 15, 1145, following an assault on the Campidoglio.

LUCIUS III (Ubaldo Allucingoli of Lucca) (d. 1185), pope from 1181 to 1185, Cistercian monk and cardinal since 1141, was elected on Sept. 1, 1181, as successor to Alexander III. He was unable to remain in Rome with its autonomy-minded republic. Unable also to agree, despite his willingness, over outstanding problems with

Frederick I, except for action against the Catharist and other heresies, Lucius died on Nov. 25, 1185, at Verona, before an open break occurred, still hopeful of promoting the Crusade cause.

See H. K. Mann, *The Lives of the Popes in the Middle Ages*, vol. 9-10 (1925).

LUCKA, EMIL (1877-1941), Austrian author and philosopher born in Vienna on May 11, 1877, came to the forefront of Austrian literature in 1912. His novels and shorter tales are as rich in thought as in invention, their plots being laid either in the Middle Ages, as in *Isolde Weissband* (1908), *Heiligenrast* (1919), *Der Weltkreis* (1919), *Fredegund* (1924); or in Vienna society, as in *Das Brausen der Berge* (1918); or in the Austrian Alps, as in *Am Sternbrunnen* (1925). In *Die drei Stufen der Erotik* (1913) Lucka gives a representation of the development of love throughout the ages; in *Grenzen der Seele* (1916) he presents the psychology of genius; and in *Urgut der Menschheit* (1924) he discusses the problem of how the primeval myths may be revived to meet the needs of modern civilization. Later works included a biography of Michelangelo (1930); a novel, *Der blutende Berg* (1931); *Die Verwandlung des Menschen* (1934); and *Die grosse Zeit der Niederlande* (1936).

LUCKENWALDE, a town of Germany which after partition of the nation following World War II was in the *Bezirk* (district) of Potsdam, German Democratic Republic. It is located on the Nuthe river, 30 mi. S. of Berlin on the railway linking Berlin with Halle and Leipzig. Pop. (1962 est.) 28,696. The site of Luckenwalde was occupied in the 12th century by a Cistercian monastery, but the place, first recorded in chronicles in 1217, did not become important till the reign of Frederick the Great, though it received a municipal charter in 1442. It belonged to the archbishopric of Magdeburg until it passed to the electorates of Saxony (1648) and Brandenburg (1680). Its cloth and hat manufactories are extensive. Other industries include brewing and the making of metal and paper products, shoes, furniture and screws.

LUCKNOW, a city, district and division of Uttar Pradesh, India. The city, headquarters of the district and division and the seat of the state government, is situated on the Gumti river, a tributary of the Ganges, 303 mi. S.W. of Delhi and 606 mi. N.W. of Calcutta. Pop. (1961) 635,590. The town was administered by a corporation after 1960. There are a number of impressive buildings representing an admixture of European and Indo-Saracenic style all constructed in the late 18th or early 19th century. The best known is the great imambara (a meeting place used mainly by Shi'a Muslims especially during the Muharram ceremonies), built in 1784, a large single-storied edifice of brick and mortar with one of the largest vaulted halls of its kind, measuring 160 ft. by 53 ft. by 50 ft. The Rumi Darwaza or Turkish gate (1784) has at its western edge a 60-ft. high arch, while the clock tower (1881) west of it is 221 ft. high. Husainabad imambara is a later construction. Shah Nazaf (1824-27), the mausoleum of Nawab Ghazi ud-Din Haider, has an interior decorated with chandeliers, which are illuminated during Muharram. Constantia, now housing La Martinière college, is of a different type, while Chhattar Manzil has a fine dome surmounted with a gilt umbrella. The best preserved monument of the city is the ruined residency built in 1800, and besieged and totally shelled in 1857 during the Indian Mutiny (called by Indians the freedom struggle).

Among modern buildings, the most outstanding are the railway station in Rajasthani style claimed to be one of the most elegant in India, the council house, the new councilor's residence, Lucknow university, Isabella Thoburn college and the stadium. A martyr's memorial on the bank of the Gumti river and facing the residency was added in 1957. Among the many parks and gardens are the Sikandar Bagh, converted in 1953 into the first national botanical garden of India, Banarsi Bagh (an open-air zoological garden), Dilkusha Bagh and Victoria park.

As a noted centre of learning the city has, besides the teaching and residential Lucknow university founded in 1921 and its constituent and associated colleges, a university of Indian music, an institute of Muslim theology and Arabic learning, the Birbal Sahni institute of paleobotany, the central drug research institute, etc.

J. K. Institute of sociology and human relations, the government college of fine arts and crafts, and a state museum. The city, well connected by roads, is a central junction of the Northern and North Eastern railways, and lies on the air route between Delhi and Calcutta. As a centre of traditional artistic industry it is well known for its *chikan* work (fine hand embroidery), *sari* and *kamdani* (gold and silver thread work), clay modeling, cotton fabrics, perfumes and ivory carving. Its large-scale industries include a distillery and a paper mill.

LUCKNOW DISTRICT, an alluvial expanse in the centre of the Indo-Gangetic plain, is traversed by the Gumti and the Sai rivers. Area 977 sq.mi. Pop. (1961) 1,338,882. Its main crops are wheat, rice gram, barley, jowar (sorghum) and bajra (pearl millet); but it is better known for its *dasher* mangoes, the best in Uttar Pradesh, and sweet melons. The other towns in the district are Malihabad, Kakori, Amethi and Gusainganj.

LUCKNOW DIVISION (area 12,037 sq.mi.; pop. [1961] 8,320,415) consists of the districts of Lucknow, Unnao, Rae Bareilly, Sitapur, Hardoi and Kheri.

(B. Sr.)

History.—According to Hindu tradition Lucknow was founded by Lakshmana, the brother of Rama of Ajodhya (Ayodhya), the legendary hero of the *Rāmāyana*. It was not until the end of the 12th century that the Muslims entered Oudh (q.v.). Local traditions, however, conflict with Muslim accounts and suggest that the Rajput chiefs maintained their power practically intact throughout the Muslim period. Lucknow was captured by Babur in 1528. After Humayun's flight in 1540 to Persia (Iran) it formed part of the dominions of Sher Shah Suri. During Akbar's reign it was incorporated in the province of Oudh. Its importance really dates from the accession of Asaf ud-Daula, who succeeded Shuja ud-Daula as nawab of Oudh in 1775. It was Asaf ud-Daula who transferred the seat of government from Fyzabad to Lucknow. His extravagance became proverbial. He built the famous imambara, the great gate of which was said to be modeled on that of the Turkish Sublime Porte at Constantinople (Istanbul). At Lucknow in 1819 Lord Hastings conferred the title of king upon Ghazi ud-Din Haider. He was succeeded by his son Nasir ud-Din Haider in 1827, whose life was wholly given over to pleasure; and the description of Lucknow during his reign in William Knighton's *Private Life of an Eastern King* (1921) is probably not exaggerated. From 1773 to 1856 Lucknow was the headquarters of the British resident in Oudh. From 1843 to 1845 Maj. Gen. Sir William Nott was stationed there as special envoy to the king of Oudh. During the Mutiny, on July 1, 1857, Sir Henry Lawrence, the chief commissioner in Oudh, retired with the European inhabitants of Lucknow and a small force of loyal sepoys into the residency. Early in the siege Lawrence was mortally wounded, but the garrison held out against enormous odds until relieved by Sir Henry Havelock and Sir James Outram on Sept. 25. The relieving force found itself besieged by the rebels until the arrival of Sir Colin Campbell (later Lord Clyde) on Nov. 16. A week later British troops were withdrawn from Lucknow which was not permanently reoccupied until March 1858. Lucknow remained the capital of a separate administration till 1877 when the post of chief commissioner of Oudh was united with that of lieutenant governor of the North-Western provinces (later the United Provinces, now Uttar Pradesh).

(C. C. D.)

LUCRETIA, a Roman lady, wife of Lucius Tarquinius Collatinus, distinguished for her beauty and domestic virtues. According to tradition, having been raped by Sextus Tarquinius, one of the sons of the king Tarquinius Superbus, she informed her father and her husband, and, having exacted an oath of vengeance from them, stabbed herself to death. Lucius Junius Brutus (see Brutus) put himself at the head of the people, drove out the Tarquins, and established a republic (traditional date, 509 B.C.). See Livy, *History of Rome*, i, 57–60.

LUCRETIVS (TITUS LUCRETIVS CARUS) (earlier half of first century B.C.), Latin poet and philosopher, whose one poem, *De*

rerum natura ("On the Nature of Things") renders in hexameters the atomic theory of Epicurus (q.v.). Its declared purpose is to free mankind from religious fears by proving that the soul is material and is born and dies with the body, and that, though gods exist, they cannot intervene to help or harm men. Apart from his poem almost nothing is known about him. What little evidence there is, is quite inconclusive. Jerome in his chronicle, for 94 B.C. (so most manuscripts; others 96 or 93 B.C.), states that Titus Lucretius the poet was born in that year; afterward he became mad from a love potion, and having written in lucid intervals some books, which Cicero afterward emended, he killed himself in his 44th year (i.e., 51 or 50 B.C.). Donatus in his "Life" of Virgil notices that Virgil put on the *toga virilis* in his 17th year, on his birthday (i.e., Oct. 15, 54 or 53 B.C., according to whether Virgil was entering or completing his 17th year), and that Lucretius died that same day; but Donatus contradicts himself by stating that the consuls that year were the same as in the year of Virgil's birth (i.e., Crassus and Pompey, consuls in 70 B.C. and again in 55 B.C.). This last date, 55 B.C., seems partly confirmed by a sentence in Cicero's reply to his brother in Feb. 54 B.C. (*Ad Quintum fratrem* 2, 9, 3). The sentence, though variously interpreted or emended, suggests that Lucretius was already dead and also that Cicero may have had something to do with the publication of his poem: "The poems (*poemata*) of Lucretius are as you write in your letter—they have many high lights of genius (*lumina ingeni*), yet also much artistry (*ars*). But more when you come." The coincidence noticed by Donatus, of Lucretius dying on the day that Virgil came of age, looks like the neat invention of literary history. Again, though Lucretius clearly died before finally revising his poem, it is surprising to find no other reference to the remarkable circumstances of his life and death alleged by Jerome. They may belong to a late story put about by Christian polemic developed perhaps from an ignorant or wishful misunderstanding of *docti juror arduus Lucreti* (Statius, *Silvae*, 2, 7, 76). Excepting the single mention in Cicero, the only contemporary who names Lucretius is Nepos (*Atticus* 12, 4) in the phrase "after the death of Lucretius and Catullus," and the only contemporary whom Lucretius names is the Memmius to whom he dedicates his poem, probably C. Memmius (son-in-law of Sulla, praetor of 58 B.C., patron of Catullus and Cinna) for whose friendship Lucretius "hopes" (i, 140).

Theme of "De Rerum Natura."—*De rerum natura* translates the title of the chief work of Epicurus, *Peri Phuseos*, as also of the didactic epic of Empedocles (q.v.), of whom Lucretius speaks with admiration only less than that with which he praises his master Epicurus (cf. i, 731 ff. with iii, 14 ff.). The poem is the fullest statement extant of the physical theory of Epicurus, but it also alludes to his ethical and logical doctrines. The argument in outline is as follows.

1. No thing is created out of nothing and no thing can be reduced to nothing. The universe is infinite: an infinite extent of empty space (or void) and an infinite number of irreducible particles of matter (or atoms), there being a finite number of different kinds of atoms, but an infinite number of atoms of each kind. Atoms differ only in shape, size and weight. They are absolutely hard, changeless, everlasting, the limit of physical division. They are made up of inseparable "minimal parts" or units, which are the limit of mathematical division. Bigger atoms have more such parts; but there is a limit to the size of atoms, and even the biggest are minute. Atoms of all kinds move always at an equal and constant velocity many times greater than the velocity of light (ii, 161 ff.). All atoms would move everlastingly downward in infinite space, and never collide to form atomic systems unless they swerved at times a minimal degree from the vertical. To these indeterminate swerves is due the creation of an infinite plurality of worlds, and also free will. All things that exist or happen consist ultimately only of matter and void: they are systems of moving atoms, separated by greater or smaller intervals of void, which cohere more or less according to the shapes of the constituent atoms. All systems are divisible and therefore perishable (except the gods). Only systems of atoms have "secondary" properties: colour, taste, heat, smell, or sensation. All change is explainable in

terms of addition, subtraction or rearrangement of changeless atoms.

2. The soul is made of atoms exceedingly fine, and has two connected parts: the *anima* distributed throughout the body, which is the cause of sensation, and the *animus* in the breast (not the head), the central consciousness where thinking, willing, and the emotions of joy and fear occur. The soul is born, grows, and dies with the body. At death it escapes, like "smoke," into the air and disintegrates more quickly than even the body.

3. The gods exist, but neither made nor manipulate the world. They themselves are creatures of the atomic process, systems of exceedingly fine atoms, human in shape, yet by some principle of existence everlasting. They live remote, in between worlds, unconcerned with human affairs, examples to men of the ideal life of perfect happiness (absence of mental fear and bodily pain). Their excellent being is perceived at times by some sort of intuition of the mind.

4. We know by sense perception; and argue by reason, correctly if according to certain rules (the *Canonica*). The senses are infallible. Reason however can make false inferences. We see objects because they discharge from their surface representative films which strike the eye. Similarly hearing, smelling, etc., are explained by atomic discharges striking the appropriate sense organ. Separate atoms are in principle imperceptible because they have no dischargeable parts. The senses perceive the existence of matter; reason infers that it exists in the form of atoms, and also that void, untouchable and so imperceptible, exists to explain the perceived movement of matter.

5. We know from feelings of pleasure or pain what we should do or not do. Our aim should be so to conduct our lives that we get, on balance, the maximum of pleasure and the minimum of pain.

Structure of the Poem.—Lucretius distributes his argument into six books, beginning each with a highly finished exordium. Books i and ii establish the main principles of the atomic universe, refuting rival theories of Heraclitus, Empedocles and Anaxagoras (*qq.v.*), and covertly attacking the Stoics. Book iii demonstrates the atomic structure and mortality of the soul, and ends with a triumphant sermon on the theme: "death is nothing to us" (iii, 830). Book iv describes the mechanics of sense perception and thought and certain bodily functions, ending with a violent condemnation of sexual love. Book v describes the creation and working of this world and the celestial bodies, the evolution of life and human society. Book vi explains remarkable phenomena of the earth and sky, in particular thunder and lightning. It ends with a description of the plague at Athens, a sombre picture of death contrasting with that of spring and birth in the invocation to Venus with which the poem opens.

Use and Adaptation of the Latin Language.—The problem of Lucretius was to render the bald and abstract prose of the Greek Epicurus into Latin, and into hexameters, at a time when Latin as yet had no philosophic vocabulary. He had to find scanning equivalents for Greek terms as well as synonyms for the sake of poetic variety. He succeeded admirably in spite of repeated complaints about "the poverty of our native speech" (i, 136 ff.). He applied common words to a technical use. So he used *concilium*, "assembly of people" for a "system of atoms," and *primordia*, "first-weavings" for the "atoms" which make up the texture of things. When necessary he invented words, e.g., *clinamen* for the "swerve," usually on the pattern of the Greek originals. In poetic diction and style his debt to the older Latin poets, especially Ennius, is apparent (i, 117; iii, 1025). He freely used alliteration and assonance, solemn and often metrically convenient archaic forms, and old constructions. He formed with almost Greek facility expressive compound adjectives of a sort rejected by Augustan taste, e.g., "the light-sleeping hearts of dogs" (v, 864), "forest-breaking winds" (i, 275). He imitated or echoed Homer, Aeschylus, Euripides, Callimachus, Thucydides and Hippocrates. His hexameters can be said to stand halfway between those of Ennius who introduced the metre into Latin, and Virgil who perfected it. An ear familiar with Virgil will notice some incoherence of rhythm due to words ending with the end of the second foot, to spondaic words occupying the fourth foot, or to

words of one or more than three syllables concluding the verse, as well as harsh elisions and examples of unusual prosody. The influence of Lucretius on Virgil is pervasive and unmistakable, especially in the Georgics, the next masterpiece of didactic poetry in Latin and it is in evident allusion to the author of *De rerum natura* that Virgil wrote *Felix qui potuit rerum cognoscere causas* ("Happy is the man who can read the causes of things") (Georgics ii, 490).

Poetical Power and Moral Fervour.—Lucretius wrote his poem with the conviction of a proselytizing convert. Epicurus to him was a saviour "god" (v, 8 ff.), greater than the mythical benefactors of mankind, Ceres, Liber or the Stoic hero Hercules. But Epicureanism seemed bitter to the "gross" of men (i, 945). So Lucretius was offering the medicine cup of beneficial wormwood, edged with the deceptive honey of poetry. His poem opens with an invocation to Venus, mother of Aeneas, mistress of Mars, the only divinity in the Pantheon competent to grant his prayer for beauty for his words and peace for the Roman world, the natural symbol of pleasure and of the creative moment in the atomic process. The argumentative runs of the poem read less "pleasantly," but are relieved by finished passages of a higher strain, more impressive in their poetical power than almost any other ancient poetry. Even in his more cobbled verses interest is sustained by his evident will to convince, and by the energy, propriety and perspicuity of his language. The style ranges from classic economy (e.g., v, 1188–1193) to the persuasive redundancies of the enthusiastic lecturer. His mind is visual. His eye notices the curious particularity of nature. The argument by analogy prescribed by the *Canonica* (that hypotheses of reason must agree with, or not contradict, sense perception) gives him his opportunity as a poet. He regularly follows an abstract exposition by a concrete picture. The constant motion of imperceptible atoms within an apparently still object he illustrates by the distant view of grazing sheep, which appear as a "white stationary gleam on a green hillside" (*stare videntur et in campis consistere fulgor*, ii, 332).

He speaks to mankind as well as to the "sons of Aeneas" in austere compassion for the ignorant, unhappy human race. His moral fervour expresses itself in gratitude to Epicurus and in hatred of the seers (*vates* i, 102) of the Greco-Roman world who inculcate religious fears (*religiones*) by threats of eternal punishment after death, of the Etruscan soothsayers (*haruspices*, vi, 381) with their lore of thunder and lightning, of the false philosophers—Stoics with their belief in divine providence, or Platonists and Pythagoreans who teach the transmigration of immortal souls. The first appearance of *religio* in the poem is as a monster which thrusts its fearful head from the augural quarters of the sky (i, 62 ff.). Epicurus, not intimidated by theological myths or by thunder and lightning, had ranged beyond the "flaming ramparts of the world" through the infinite universe, broken into the citadel of nature, and brought back in triumph the knowledge of what can and what cannot be, of that "deep-set boundary stone" which divides the separate properties of things, the real from the not-real. "So religion is crushed beneath our feet and his victory lifts us to the skies" (i, 78 ff.).

LUCULLUS, LUCIUS LICINIUS (c. 117–58/56 B.C.) a Roman general who fought Mithradates VI Eupator of Pontus from 74 to 66, and from whose high standard of living on his return to Rome the word "Lucullan" derives. He was a protégé of Sulla, serving in the east as quaestor in 87 and proquaestor from 86 to 80. He was aedile in 79 and praetor in 78, when Sulla died, having entrusted Lucullus with the publication of his memoirs and made him guardian of his son.

Consul in 74 when Bithynia, bequeathed by King Nicomedes IV to Rome, was invaded by Mithradates, he intrigued to secure the

military command against him and was appointed governor of Cilicia and later, in addition, of Asia. At the head of five legions (two of which, the "Valeriani" or "Fimbriani," had murdered their first commander L. Valerius Flaccus in 85) he drove Mithradates from Cyzicus in winter 74/73, defeated him at Cabira in 72, and except that Mithradates was still at large (in Armenia, whose king Tigranes was his son-in-law) the war seemed over by 70, when the senate appointed a commission of ten to join Lucullus in drawing up a charter for the new province of Bithynia-Pontus. But business circles in Rome turned against him because their profits were cut by the reforms he effected in winter 71/70 on behalf of the provincials, who were staggering under overdue interest on unpaid instalments of the heavy indemnity imposed on them by Sulla; and, in the east, Tigranes, having rejected the Roman proposal that he should surrender Mithradates by treachery, had joined Mithradates as an active ally. Lucullus attacked Armenia, defeating Tigranes and capturing his capital Tigranocerta in 69. He planned further aggression still, but he handled men badly and, despite good military leadership, small casualties and extensive loot, his troops mutinied twice in 68 and again, encouraged by Lucullus' brother-in-law P. Clodius, in spring 67 at Nisibis. Finally in 66, Mithradates having recovered much of his territory, Lucullus (who had already been ineffectively superseded in Bithynia by Manius Acilius Glabrio, consul of 67) was instructed by a bill of the tribune Manilius to hand over his command to Pompey.

At Rome his triumph was conceded but delayed until 63. After that, an immensely wealthy man, he lived in great extravagance, occasionally intervening in politics as a disgruntled and spineless optimist, more seriously occupied with cultural pursuits. He died between 58 and 56 B.C.

(J. P. V. D. B.)

LUCUS FERONIAE, the name of a small Faliscan town of which there are remains on the right bank of the Tiber, near Scorano, 35 km. (22 mi.) N. of Rome, Italy. Its name derives from the grove, and later temple, of the ancient Latin divinity Feronia, which was its principal monument. The long controversy as to its location was resolved by the discovery in 1952 of inscriptions naming the site and by the subsequent excavation of the centre of the ancient town. Already a substantial market in the 6th century B.C. (Livy), it was sacked by Hannibal in 211. Veterans were settled there, possibly by Sulla and certainly by Augustus, under whom it took the title of Colonia Julia Felix Lucus Feroniae. Its history under the empire is one of steady decline. The latest dedication recorded by the early 1960s was to the emperor Gallienus in A.D. 266, and by 305–306 many of the public buildings had fallen into ruin.

The principal surviving remains are those of the late republican forum, with a flanking portico containing shops and offices; a basilica of Vitruvian plan, with an annexed shrine containing a rich series of Julio-Claudian dedications and incorporating the city treasury; a small republican temple; the Augustan aqueduct; a fountain and public latrines. The uncleared sites of the temple of Feronia, the baths, theatre and amphitheatre were discovered from air photographs.

LUCY, SAINT, a martyr at Syracuse in Sicily, probably during Diocletian's persecutions, whose veneration is attested by a 5th-century inscription found at Syracuse. Her legend, which is historically worthless, relates how she was martyred for refusing to marry because she had taken a vow of virginity. It closely resembles that of St. Agnes and other virgin martyrs, and was widely diffused: the English St. Aldhelm (d. 709) used it in his *De laudibus virginitatis* and *De laudibus virginum*. St. Lucy is named in the canon of the Roman Mass, and her feast day is Dec. 13. Probably because of her name (*lux*, "light") she is in-

voked by those with eye trouble, and is sometimes represented in art with a dish containing her eyes which were said to have been torn out by her persecutors. There was much popular devotion to St. Lucy and she was well known in folklore; for example, the saying "Lucy-light, shortest day, longest night."

See H. Thurston and D. Attwater (eds.), *Butler's Lives of the Saints*, rev. and supplemented, vol. iv, pp. 548–549. (1956). (D. A.R.)

LUCY, SIR HENRY (1845–1924), British journalist, was born at Crosby, near Liverpool, on Dec. 5, 1845. Educated in Liverpool, he began life in a Liverpool merchant's office, but soon became a reporter for a Shrewsbury periodical. In 1870 he joined the staff of the *Pall Mall Gazette* (London) and in 1873 became parliamentary reporter to the *Daily News*, with which paper he had a long connection in various capacities. In 1881 he also joined the staff of *Punch* and won a great reputation as the contributor of its parliamentary sketch signed "Toby, M.P." He was knighted in 1909 and retired from parliamentary work in 1916. He published his autobiography, *Sixty Years in the Wilderness*, in 1909, and *The Diary of a Journalist* in 1920. He died on Feb. 20, 1924.

LUCY, RICHARD DE (d. 1179), chief justiciar of England under Henry II, came from Lucé near Domfront in western Normandy, and probably entered royal service under Henry I. He is recorded as a supporter of Stephen from about the year 1140, succeeding Geoffrey de Mandeville as justiciar and sheriff of Essex (1143). Henry II made him and Robert de Beaumont, 2nd earl of Leicester, chief justiciars jointly (c. 1155), and after Leicester's death in 1168 Lucy held the office alone. As one of the king's chief councilors, he must be given part of the credit for the important legislation of the period, and during the struggle with Becket he was singled out by the king's enemies as a principal author of the Constitutions of Clarendon (1164). His role in holding together those loyal to the king in the great revolt of 1173–74 was crucial. In 1179 he resigned his office and entered the religious life at Lesnes abbey, Erith, Kent, founded by himself in 1178 in penance for his part in the events leading to Becket's death. He had been excommunicated by Becket in 1166 and again in 1169, and the archbishop's murder had been in part provoked by his refusal to lift the sentences he had passed upon his enemies. Richard de Lucy died at Lesnes on July 14, 1179.

See J. Boussard, *Le gouvernement d'Henri II Plantagenet* (1956). (G. W. S. B.)

LUCY, SIR THOMAS (1532–1600), English Warwickshire squire, traditionally associated with the youth of Shakespeare, was born on April 24, 1532, the son of William Lucy of Charlecote, near Stratford-upon-Avon. As a boy he is said to have been under the tutorship of John Foxe, the martyrologist, from whom he learned the Puritan principles which distinguish his adult life. He was married at 16 to Joyce Acton, sole heiress to her father Thomas Acton of Sutton, Worcestershire. With her fortune he was able to rebuild the family house, beginning probably soon after his father's death in 1551. He was knighted in 1565, and sat in two parliaments as knight of the shire for Warwick. He was a justice of the queen's peace, a commissioner for musters at the time of the Armada, a commissioner for recusancy, and a member of Burleigh's council for the marches of Wales. After his part in the arrest and execution of Edward Arden in 1583 he became widely respected and feared as a recusant hunter. He died suddenly at Charlecote on July 7, 1600.

In 1709 Nicholas Rowe, in the preface to his edition of Shakespeare, told the story that Shakespeare had been concerned, in his youth, in stealing a deer from Charlecote park, and had been prosecuted by Lucy. In revenge, Shakespeare had written a ballad on Lucy, and the trouble which resulted compelled him to leave Stratford for London. Critics have disputed the truth and the details of this story ever since, but 20th-century opinion tends to regard it as largely legendary, with a possible kernel of truth. Shakespeare is also supposed to have caricatured Lucy in his portrait of Justice Shallow, who appears in 2 *Henry IV* and again in *The Merry Wives of Windsor*. Amid all the controversy on this question there are only four certain facts: *The Merry Wives* was written about 14 years after the alleged deer stealing; there

is a reference in that play to the white laces "that do become an old coat well"; Shallow's threat to make a Star Chamber case of a poaching incident; and the general mockery of justices of the peace. In the opinion of most 20th-century critics this is insufficient evidence to substantiate the claim that Shakespeare intended Shallow to be a recognizable portrait of Lucy.

BIBLIOGRAPHY.—The fullest account of Lucy is in A. Fairfax-Lucy, *Charlecote and the Lucys* (1958). See also C. C. Stopes, *Shakespeare's Warwickshire Contemporaries*, 2nd ed. (1907); E. K. Chambers, *William Shakespeare*, vol. i, pp. 18-22 (1930); J. L. Hotson, *Shakespeare versus Shallow* (1931).

(B. R. M.)

LUDDITES, the name given to organized bands of English rioters for the destruction of machinery, who first appeared in Nottingham and the neighbouring districts toward the end of 1811. The "Ludds" or Luddites were generally masked, and operated at night. Their leader, real or imaginary, was known as "King Ludd" from a probably mythical "Ned Ludd." Great distress had been caused by the dismissal of handicraftsmen in the areas in which textile machinery was introduced; and even those handicraftsmen who did not lose their employment suffered considerable worsening of conditions owing to competition. There had been previous machine-breaking disturbances in the 18th century, but they were less contagious than the Luddite disturbances. The riots began with the destruction of stocking and lace frames, and, continuing through the winter and the following spring, spread into Yorkshire, Lancashire, Derbyshire and Leicestershire. The riots were directed not merely against reductions of wages but also against the poor quality goods (especially stockings) produced by the new machines. The rioters were sometimes supported by local public opinion, and they abstained from bloodshed or violence against living beings, until in 1812 a band of them was shot down by soldiers at the request of a threatened employer, Horsfall, who was afterward murdered. They were met by severe repressive legislation, introduced by Lord Liverpool's government. A notable feature of the opposition to the legislation was Lord Byron's speech in the house of lords. The organization was temporarily broken up by a mass trial at York in 1813, which resulted in many hangings and transportations. Among the victims was probably the real "King Ludd," for the elaborate organization suddenly collapsed. In 1816 similar rioting was resumed, caused by the depression that followed the peace of 1815 and was aggravated by one of the worst of recorded harvests. In that year, although the centre of the rioting was again in Nottingham, it extended over almost the whole kingdom. The rioters were also thoroughly organized. While part of the band destroyed the machinery, sentinels were posted to give warning of the approach of the military. Vigorous repressive measures, and, especially, reviving prosperity, brought the movement to an end. It has been commemorated in fiction, notably in Charlotte Brontë's novel *Shirley* (1849). *Ben o' Bills* by D. F. E. Sykes (1898) is a "novel" in which is concealed much genuine history written from a Luddite point of view.

(A. BRI.)

LUENDORFF, ERICH (1865-1937), German general who was mainly responsible for military policy and strategy in the latter years of World War I, was born at Kruszwia near Posen (Poznan) in Prussian Poland on April 9, 1865, of an impoverished landowning family. This background and his father's bankruptcy had a permanent influence on the son who, throughout his life, remained an austere figure without a spark of humour.

Ludendorff entered the army through the cadet corps, became an infantry officer and, from 1894 onward, served almost continuously on the general staff. From 1908 to 1912 he was head of the deployment section and thus responsible for the detailed planning for the invasion of France and Belgium. He appears to have had no thoughts outside his work, his only relaxation being short periods of travel in pursuit of military knowledge: he once remarked that, apart from strictly military literature, he had never read a serious book in his life.

From 1912 to 1914 Ludendorff commanded an infantry brigade; but on mobilization in July 1914 he was posted to headquarters, 2nd army, as quartermaster general. The German plan of operations in the west when World War I broke out hinged on the speedy capture of the Belgian fortress of Liège; and Ludendorff,

who was familiar with every detail of the arrangements, was attached as liaison officer with the commander of the force which was to effect the capture. He personally led the body of troops which seems to have surprised the garrison by infiltration. The fortress and all the outlying forts of Liège were captured in 48 hours with very small losses.

Because of the threat of a large-scale Russian invasion of East Prussia, the elderly Gen. Paul von Hindenburg was recalled from retirement to take command of the 8th army in the east, and Ludendorff was appointed as his chief of staff. The chief of staff of a German army had two loyalties: on the one hand to his commander, on the other to the chief of the general staff at supreme headquarters. This resulted in the chief of staff's possessing power and authority to a degree unknown in other armies. Not infrequently the nominal commander became a figurehead and the chief of staff the commander in all but name. This system determined the partnership of Hindenburg and Ludendorff.

By a series of lightning moves, Hindenburg and Ludendorff won two great victories over the Russians (Aug.-Sept. 1914); but they were not decisive and did no more than stabilize the eastern front for the time being. Thus Hindenburg and Ludendorff remained in charge of a vastly expanded eastern front until the end of Aug. 1916. By that time the policy of Erich von Falkenhayn (the chief of the general staff) had become discredited, and the emperor William II then appointed Hindenburg (with Ludendorff as his first quartermaster general) to assume supreme military control. Ludendorff's first task was to secure some improvement on the western front, where German failure to capture Verdun, together with heavy losses both there and on the Somme front, had created a dangerous situation. This was eased in March 1917 by withdrawal to the "Hindenburg line."

Ludendorff now became increasingly involved in political matters. Though he never advocated military dictatorship he constantly reiterated his desire for a "strong policy," by which he meant government by civilians who would acquiesce to the measures he and Hindenburg considered necessary (the fall of Theobald von Bethmann Hollweg and the appointment of Georg Michaelis as chancellor were largely contrived by Ludendorff). It was here that Ludendorff's limited outlook became apparent. During the early operations on the eastern front he had proved himself a fine campaign strategist, but the broader strategy of supreme control was beyond him, as were the problems of finance, industry, social changes and foreign policy in which he interfered. He did much to formulate the terms of the treaties of Brest-Litovsk and of Bucharest and the German plans for a puppet kingdom of Poland; he was also a strong advocate of unrestricted submarine warfare.

The collapse of Russia at the end of 1917 enabled the high command to transfer troops from the eastern to the western front. Ludendorff judged that the time was ripe for an all-out effort, and elaborate preparations were made for an offensive in the early spring of 1918. The front selected was that held by the numerically weak British 5th army; the objective being the important communications centre of Amiens. The offensive opened on March 21, 1918, and met with considerable initial success, but by the first days of April its impetus had flagged and Amiens was never reached. This offensive was followed by others—at Lys (April 9), Chemin-des-Dames (May 27), Metz (June 9) and Reims (July 15). By the end of July the German armies had shot their bolt: Ludendorff's final bid for victory had failed and the Allied armies were themselves about to begin the final and decisive offensive of the war. After the collapse of Turkey and Bulgaria, Ludendorff fell into extreme despondency and on Sept. 20 peremptorily demanded that the imperial government should at once conclude an armistice and sue for peace. However, he recovered sufficiently to oppose violently the new government of Prince Max of Baden, who had the strength to dismiss him on Oct. 26.

On the signing of the Armistice (Nov. 1918), Ludendorff fled to Sweden, where he wrote his war memoirs. He returned to Germany in the spring of 1919 and became the leader of a reactionary political movement and the apostle of a "Nordic" religion, con-

concentrating on the fight against Freemasons, Jesuits, Jews and Marxists. He backed Hitler in his unsuccessful Munich *Putsch* of Nov. 8, 1923: only his past services saved him from the consequences. In May 1924 he entered the *Reichstag* as a National Socialist; and in 1925 he stood, unsuccessfully, for president of the *Reich*. Later Hitler and Ludendorff became bitter enemies. Ludendorff died at Tutzing on Dec. 20, 1937. His publications were *Meine Kriegserinnerungen* (1919; Eng. trans., *My War Memoirs*, 1914–1918, 1919); *Kriegführung und Politik* (1922); and *Mein militärischer Werdegang* (1933).

See H. Delbrück, *Ludendorffs Selbstporträt*, 10th ed. (1922); W. Görtitz, *The German General Staff: Its History and Structure*, Eng. trans. (1953). (C. N. B.)

LÜDENSCHIED, a town of Germany which after partition of the nation following World War II was located in the *Land* (state) of North Rhine-Westphalia, Federal Republic of Germany. It lies in the wooded Sauerland at the watershed of the Lenne and Volme rivers, 19 mi. S.E. of Hagen at an altitude of 495 m. (1,624 ft.). Pop. (1961) 58,239. The main business street, the Wilhelmstrasse, joins several other streets at the city centre, while at the centre of the old town is the Church of the Saviour with a tower dating from 1072. There is a modern hospital, a park and recreational facilities. Lüdenscheid is an industrial centre and manufactures aluminum, plastics and synthetics, light metal products and rolled and semi-finished goods.

A Frankish settlement in the 9th century and chartered in the mid-13th century, Lüdenscheid became during the middle ages a centre of the iron industry, and was a member of the Hanseatic league. In the 17th century it passed with Cleves-Mark to Brandenburg; during the French occupation of 1806–15 it belonged to the grand duchy of Berg. In 1723 the town was destroyed by fire. (R. A. Kr.)

LÜDERITZ (formerly *ANGRA PEQUENA*), a lighterage port in South West Africa, 419 nautical miles N.N.W. of Cape Town, S.Af., by sea. Pop. (1960) 3,604. Entry is forbidden to large areas (*Sperrgebiet*) of the Namib desert hinterland because diamonds are present. Rainfall is about 0.6 in. annually and the town depends on condensed sea water. A railway links Lüderitz with the main South West African system at Seeheim (197 mi. E.) and a single road crosses the restricted area to Aus (83 mi. E.). Lüderitz is a health and holiday resort. Rock lobsters and fish meal are processed; other industries are seaweed milling, sealing, guano recovery and boatbuilding. Bartolomeu Dias de Novais (q.v.) erected a cross (replaced by a replica) on a rocky promontory nearby in 1487. He named the bay Angra Pequena. In 1883 the German merchant Franz Adolf Lüderitz established a trading post there. Diamonds were discovered in 1908 but after a period of development mining activities were transferred to richer fields near the mouth of the Orange river. The town was renamed Lüderitz in 1921. (P. D. du P.)

LUDFORD, NICHOLAS (c. 1485–c. 1557), one of the most important English composers of the early Tudor period. Though mentioned in Thomas Morley's list of English authors consulted in the preparation of his famous *Plain and Easy Introduction to Practical Music* (1597), Ludford otherwise went unnoticed until the 20th century. Very little is known of his life. He was admitted to the Fraternity of St. Nicholas, the guild of parish clerks of the city of London, in 1521, and was identified as a verger in the dissolution certificate of the collegiate church of St. Stephen's, Westminster, in 1547; he was still receiving a pension in 1555–56. Eleven of his Masses have survived complete. These comprise a set of seven daily Lady Masses, complete with Propers, unique in English music, and four large-scale festal Masses; there is also a fine Magnificat that is musically related to his Mass *Benedicta*.

BIBLIOGRAPHY.—Hugh Baillie, "Nicholas Ludford (c. 1485 c. 1557)," in *The Musical Quarterly*, xlv (1958); J. D. Bergsagel, "An Introduction to Ludford," in *Musica Disciplina*, xiv (1960); *The Collected Works of Nicholas Ludford*, ed. by J. D. Bergsagel (1963–). (Jo. D. B.)

LUDHIANA, a city and district of the Jullundur division in Punjab, India. The city, which is 194 mi. N. of Delhi by rail, is situated on the old bank of the Sutlej river, 8 mi. S. of the present river bed. Pop. (1961) 244,032. The city was founded in 1480

by two members of the Lodi dynasty (then ruling in Delhi) from whom it derives its name. It stands on the Grand Trunk road, and commands a strategic crossing over the Sutlej. The railway line divides the city into two parts. To the north is the old town with a network of narrow alleys along which the houses are huddled together. Chaura Bazaar is the chief shopping centre. Industry is concentrated in Millerganj and in the newly developed areas. The residential areas (civil lines, Model town, Gurdev Nagar and Modelgram) lie to the south. The five arts and science colleges (two for women) and the colleges of agriculture, medicine, engineering and teachers' training are all affiliated with Panjab university. There is a U.S. Presbyterian mission which runs the medical college and a hospital.

Ludhiana is an important railway junction on the Northern railway, connected with Amritsar and Delhi by the main line, and with Ferozepur and Hissar by branch lines. The city is one of the largest manufacturing centres of hosiery goods in India, employing 7,000 workers, and the old fort is occupied by the government hosiery institute. The manufactures are chiefly exported to Ceylon, Burma, Nepal, Indonesia, east Africa and Iraq. The production of cotton textiles, bicycle spare parts, hosiery and sewing machines are the other main industries. The town is also an important wholesale trade centre.

LUDHIANA DISTRICT (area 1,324 sq.mi.; pop. [1961] 1,022,519) is a flat alluvial plain with a strip of flood plain along the Sutlej river. Average annual rainfall is 24.41 in. Agriculturally it is one of the most productive districts of Punjab with about 80% of the total area under cultivation, of which more than 40% is irrigated by the Sirhind canal and wells. Wheat, maize (corn), peanuts, millet, sugar cane and cotton are the principal crops. Jagraon (pop. [1961] 29,617), Samrala (5,439), Khanna (24,416) and Raikot (11,239) are the municipal towns and centres of local trade. (O. P. B.)

LUDLOW, EDMUND (c. 1617–1692), English parliamentarian general, whose memoirs set out his republican views, was the son of Sir Henry Ludlow of Maiden Bradley, Wiltshire. He went to Trinity college, Oxford, and was admitted to the Inner Temple in 1638. When the English Civil War broke out, he engaged as a volunteer in the life guard of Lord Essex and served through successive campaigns until 1646, when he was elected member of parliament for Wiltshire and attached himself to the republican party. He was one of the chief promoters of Thomas Pride's purge in 1648, was one of the king's judges and signed the warrant for his execution. In February he joined the council of state.

In Jan. 1651 Ludlow was sent to Ireland as second-in-command to Henry Ireton and as one of the commissioners for civil government. Ireton, the deputy of Ireland, died on Nov. 26, 1651, and Ludlow then held the chief command and had practically completed the conquest of Ireland when he resigned his authority to Charles Fleetwood in Oct. 1652. On returning to England in Oct. 1655 he was arrested, as he refused to acknowledge Oliver Cromwell's authority as protector, but he was allowed to retire to Essex. Ludlow sat in Richard Cromwell's parliament of 1659, but opposed the continuance of the protectorate. He was a member of the restored Rump parliament and of its council of state. In July 1659 he was sent to Ireland as a commander in chief but returned to England in October and, after a brief visit to Ireland at the end of the year, was impeached. Ludlow, having vainly sought to oppose the Restoration, surrendered to the speaker on June 20, but, finding that his life was not assured, although he was not named for capital punishment, he escaped to Switzerland, where he lived at Vevey. He came back to England in 1689 but was forced to return to Vevey, where he died in 1692.

See E. Ludlow, *Memoirs*, ed. by C. H. Firth (1894).

LUDLOW, a market town and municipal borough of Shropshire, Eng., stands on a hill on the left bank of the Teme below its confluence with the Corve, near the Herefordshire border. It is 28 mi. S. of Shrewsbury by road and 24 mi. N. of Hereford. Pop. (1961) 6,796.

The castle, occupying a commanding position, was probably begun in 1085 by Roger de Lacy, with modifications up till the

16th century; it fell into ruins during the 18th century. The Norman keep, the late-Norman circular chapel, the Decorated Gothic state rooms and the Mortimer and Pendover towers are interesting features. John Milton's masque *Comus* was first performed in the great hall (1634) and Samuel Butler, when steward of the castle (1661–62), is thought to have written the first part of *Hudibras* in the room over the 14th-century gateway. Ludlow was laid out on the grid pattern in the 12th century, after the castle was built. Its position ensured it an important place in the military and commercial life of the middle ages. In the 13th century it was fortified with an encircling wall. It was at that time a borough by prescription, having received its first charter in 1189. The burgesses owed most of their privileges to their allegiance to the house of York, the castle having passed in 1425 to Richard, nephew of Edmund Mortimer, who was created duke of York in 1426. In 1461 his son was crowned King Edward IV, the castle became royal property and the town received a royal charter. Thanks to its strong position, Ludlow was the last Shropshire fortress to yield to the parliamentary forces in 1646. The confirmation of early charters in 1665 continued in force until the Municipal Corporations Reform act of 1835. The Council of the Marches held its court at Ludlow castle from the reign of Henry VII until 1689.

The greater portion of the old town wall, together with one of the original seven gates, still remains. The town has many fine half-timbered buildings and several Georgian houses. The parish church of St. Lawrence is of great size with a lofty central tower and some 14th- and 15th-century glass; the ashes of A. E. Housman, the poet, are buried in the churchyard. The grammar school, founded by the Palmers' guild in the 13th century, moved to its present 15th-century building in 1533, since when it has had many additions. There is a county high school for girls (1910). The Butter Cross, an 18th-century building now a museum, and the guildhall (rebuilt 1768) belong to the corporation. The Roman Catholic church is in oriental style. The medieval Ludford bridge over the Teme has been declared an ancient monument. Ludlow is now a thriving market town, a noted centre for sales of Hereford cattle, and a business, social and tourist centre. There are several industries connected with agriculture and light engineering works have been introduced since World War II.

LUDMILA, SAINT (d. 921), wife of Borivoj, the first of the Czech princes to adopt Christianity in 874, and grandmother of St. Wenceslas, was born at Psovka, near Melnik. Her relationship with her daughter-in-law Drahomira, mother of Wenceslas, turned into a feud that ended with Ludmila's murder on Drahomira's instigation in 921. Ludmila was known as a pious woman, who had brought up Wenceslas in the faith, and oral tradition soon surrounded her with a martyr's halo. Only a short time elapsed before the first legends arose: a "prologue on St. Ludmila" in Church Slavonic, one of the oldest works to have arisen independently on Bohemian territory, and a Latin life based on it. The best-known legend is the Latin life of both Wenceslas and Ludmila written by the monk Christian in the 10th century. Ludmila's feast day is Sept. 16.

See J. Pekar, *Die Wenzels- und Ludmilalegenden* (1906).

LUDWIG, EMIL (1881–1948), German writer, the author of a number of effective and popular biographies, was born in Breslau (now Wrocław, Pol.) on Jan. 25, 1881. His father was a Jewish doctor who changed his name from Cohn to Ludwig. Emil Ludwig studied law at the University of Breslau, but soon devoted himself to writing, mainly plays and verse. During World War I he worked for a Berlin paper as foreign correspondent, at the same time writing novels, sketches and more plays. He then began to develop his talent for "humanizing" historical biography in a series of books in which the main emphasis was laid on the psychological motive. His style was vivid, even flamboyant, and his works achieved international popularity, being widely translated, although they won more favour with the general public than with historians. Clever, stimulating and controversial, with considerable psychological insight, his books lack both historical method and historical manner. His works include biographies of Goethe (1920 and 1923; Eng. partial trans. 1928), Bismarck (1913, ex-

panded 1926; Eng. trans. 1927), Napoleon (1925; Eng. trans. 1926), the emperor William II (1926; Eng. trans. 1927) and Lincoln (1930; Eng. trans. 1930). Ludwig died on Sept. 17, 1948, near Ascona, Switz.

See N. Hansen, *Der Fall Emil Ludwig* (1930); W. Mommsen, "Legitime" und "illegitime" Geschichtsschreibung (1930).

LUDWIG, KARL FRIEDRICH WILHELM (1816–1895), German physiologist, one of the founders of 19th-century German physiology and teacher of many notable physiologists, was born at Witzenhausen, near Cassel, on Dec. 29, 1816. He studied at Erlangen and at Marburg, where he taught anatomy and physiology until 1849. He then became professor at Zürich, Switz. Subsequently he went to Vienna and later organized the newly created chair of physiology at Leipzig, 1865–95. He died in Leipzig on April 23, 1895.

Ludwig was ingenious in devising instrumentation for the study of physiological processes. To be especially mentioned are his adaptation of the Thomas Young kymograph for recording arterial blood pressure and respiration and the floating writing point on the mercury manometer introduced by J. L. M. Poiseuille.

His researches comprised a variety of fields. All modern theories of urine and lymph formation stemmed from his original communication on urine secretion (1844). He devised the first blood gas pump and the first instrument for determining the velocity of blood flow in the larger arteries (*Stromuhr*). With Élie de Cyon he discovered the depressor nerve (1866) and with Baxt the accelerator nerves to the heart. He studied the effect of certain drugs on the heart with Oswald Schmiedeberg and Sir Thomas Lauder Brunton, localized the vasomotor centre in the medulla and studied capillary blood pressure. With Wooldridge he studied certain phases of the coagulation of the blood and with H. P. Bowditch discovered the all-or-none law (*q.v.*) of cardiac muscle and the indefatigability of nerve.

Ludwig was the first to demonstrate that human digestive glands might be under the influence of secretory nerves, when he demonstrated that the chorda tympani nerve had such an effect on the submaxillary and sublingual glands. He also demonstrated that stimulation of the *nervi erigentes* caused a vasodilation.

See the biography by Walter J. Meek in the *Gamma Alpha Record*, vol. xxiii, no. 2, pp. 31–43 (May 1933).

LUDWIG, OTTO (1813–1865), German writer remembered for his realistic stories, which contributed to the development of the *Novelle*, was born at Eisfeld, Thuringia, on Feb. 12, 1813. Showing an early aptitude for both literature and music, he was sent to Leipzig in 1839 to study music under Mendelssohn. Later he changed to literary studies, in particular dramatic theory, his principal interest from 1844 to 1849, when he lived in Meissen. His last years were spent in Dresden, where he died on Feb. 25, 1865. His work is *Heimatkunst* (regional art) at its best; he coined the expression "*Poetischer Realismus*," later used to describe the writing of several of his contemporaries. An admirer of Shakespeare but a sharp critic of Schiller, Ludwig strove to create dramas embodying his theories. *Der Erbfürster* (1850), an attempt to depict the psychology and environment of the middle class, owes much to the Schillerian tragedy, despite Ludwig's efforts to avoid this effect. His other plays are forgotten, but his graphic stories of Thuringian life are still read, e.g., *Die Heiterethei* (1854), the humorous tale of a village love affair, and the psychological masterpiece *Zwischen Himmel und Erde* (1855; Eng. trans., *Between Heaven and Earth*, 1928), in which a tragic conflict between two brothers is played out against the background of the slaters' trade. Ludwig's collected works were published by A. Stern and E. Schmidt (6 vol., 1891); unfinished critical edition by P. Merker (6 vol., 1912–22).

For biographies, studies and other editions see W. Kosch, *Literatur-Lexikon*, vol. ii (1953), pp. 1587–88.

LUDWIGSBURG, a town of Germany which after partition of the nation following World War II was located in the *Land* (state) of Baden-Württemberg, Federal Republic of Germany. It lies on the Neckar, 14 km. (9 mi.) N. of Stuttgart by road. Pop. (1961) 73,512. The town is celebrated for its many baroque buildings, chief of which is the former royal palace, the largest

baroque castle in Germany, set in a well-laid-out park. It contains 452 rooms, including the gallery of the ancestors of the Württemberg dynasty, a portrait gallery, a chapel, a theatre and the burial vault of the rulers of Württemberg. In the knights' hall the monthly Ludwigsburg castle concerts take place. An annual garden show, "Flowers and Baroque," with a fairy-tale garden, is held in the park. Ludwigsburg is on the Stuttgart-Frankfurt railway; another line runs to Karlsruhe. Machines, iron and wire goods, bird cages, organs and pianos, brewing machines and textiles are manufactured and the town has an important savings bank for house building. From 1758 to 1824 the town produced the famous Ludwigsburg porcelain. Founded at the beginning of the 18th century by Duke Eberhard Ludwig of Württemberg, Ludwigsburg was enlarged by Duke Karl Eugen.

LUDWIGSHAFEN, a city and river port of southwest Germany, after partition of the nation following World War II in the Land (state) of Rhineland-Palatinate, Federal Republic of Germany, is an industrial and commercial centre and the gateway of the wine-growing region. Pop. (1961) 165,761. On the Rhine, facing Mannheim, it was established early in the 17th century as a bridgehead on the left bank of the river. It was named by Louis I, king of Bavaria, in 1843 but was not made a town until the 1850s. The city is noted for its large chemical industry, established there in the mid-1860s, which produces aniline dyes, fertilizer, alkali and other products; there are also manufactures of metal, glass and pharmaceutical machinery. Trade in iron, coal and agricultural products was fostered by the opening of the harbour in 1897, and the town is an important railway junction.

The city was severely bombed during World War II. After the war, athletic events in the new Southwest stadium (capacity 85,000) attracted international participation and interest, and tourist services were important to the economy.

The pilgrimage church of Maria Himmelfahrt (1774-77) is in the Oggersheim district, where Schiller lived after fleeing from Stuttgart.

LUEGER, KARL (1844-1910), co-founder of the Christian Social party of Austria and burgomaster or mayor of Vienna, was born in Vienna on Oct. 24, 1844, the son of a caretaker at the Polytechnic institute. He received a careful upbringing at the Theresianum, studied law in Vienna and early became interested in social problems. Elected to the Vienna municipal council in 1875 and to the Austrian parliament in 1885, he won popularity by concerning himself with the petty questions of the day and by zealously exposing cases of corruption. Though he was not himself an anti-Semite and regarded German nationalism with skeptical antipathy, he did not scruple to exploit the prevalent anti-Semitic and nationalistic currents in Vienna for his own demagogic purposes. He had no part in the constitution of the Christian Social union (1887), but was one of the founders of the Christian Social party, which emerged in 1889. The most effective champion of this party, he won for it more than two-thirds of the seats on the Vienna municipal council in 1895; but because of Lueger's reputation as an agitator the Austrian prime minister, Graf Badeni, advised the emperor Francis Joseph not to confirm his appointment as mayor. In the spring of 1897, however, the emperor finally yielded to the pressure of public opinion and confirmed Lueger's appointment. As mayor, Lueger proved better than his reputation: he reorganized the gas supply and the tramway system, developed parks and gardens in the city and rebuilt schools and hospitals. Moreover, the introduction of universal suffrage (1905-06) was largely due to his efforts; and he played a decisive part in launching the Christian Social party's plan for the federalization of the empire as a means of solving the problem of the nationalities from 1905 onward. His energies, however, were sapped by a rapidly worsening illness, and he died on March 10, 1910.

See K. Skalník, *Dr. Karl Lueger: der Mann zwischen den Zeiten* (1954). (K. O. v. A.)

LUFFA (LOOFAH), the name given to the fruit of the sponge gourd (*Luffa cylindrica*), a herbaceous plant of the family Cucurbitaceae (q.v.). See also GOURD.

LUGANO (Ger. LAUIS), the largest town in Ticino canton, Switz., is situated on the shore of the Lake of Lugano, 200 km.

(124 mi.) from Lucerne and 83 km. (51½ mi.) from Milan, Italy, by rail. It is the seat of a bishop with jurisdiction over the Italian-speaking parts of Switzerland. Pop. (1960) 19,758, almost all Italian speaking. To the south is Monte San Salvatore (2,992 ft.), to the east, Monte Brè (3,061 ft.), and to the southeast (across the lake), Monte Generoso (5,584 ft.); the first two are accessible by funiculars and the last-named by steamer to Capolago and from there by cogwheel railway.

Though politically Swiss from 1512, Lugano is Italian in appearance and character. The cathedral of San Lorenzo in part dates to before the 15th century. The church of Santa Maria degli Angioli, built about 1499 and until 1848 occupied by Franciscans, contains several frescoes by Bernardino Luini. One of the greatest private art collections in Europe is in the Villa Favorita in Castagnola. Situated on the St. Gotthard railway line, which is connected to the quays by funicular railway, Lugano is much frequented by tourists. They are the city's most important source of revenue, but there is some industry including chocolate and machine manufacturing. During the struggle of 1848-66 to expel the Austrians from Lombardy, Lugano served as headquarters for Mazzini. Books and tracts intended for distribution in Italy were produced there and at Capolago, beyond the reach of the Austrian police. (P. BL.)

LUGANO, LAKE OF (Italian LAGO DI LUGANO; anc. LACUS CERESIVS), lies partly in Italy and partly in Switzerland, between Lake Maggiore and Lake Como. The great promontory of San Salvatore (2,992 ft.) nearly cuts off the western arm from the main lake. The area is 50½ sq.km. (19½ sq.mi.), of which about 46 sq.km. (18 sq.mi.) are in the Swiss canton of Ticino, formed in 1803 out of the conquests made by the Swiss from the Milanese in 1512. The remainder of the area is in the Lombardy region of Italy, to which also belongs the small enclave of Campione, almost opposite the town of Lugano, Switz. The lake lies among the outer spurs of the Alps that divide the Ticino basin from that of the Adda, where the calcareous strata have been disturbed by the intrusion of porphyry and other igneous rocks. It is fed by numerous torrents issuing from short glens in the surrounding mountains, and is drained by the Tresa, an unimportant stream flowing into Lake Maggiore. The greatest length of the lake is about 22 mi., the greatest width 2 mi. and the greatest depth 945 ft.; the surface is 889 ft. above sea level.

Between Melide, Switz., south of the town of Lugano, and Bissone, on the eastern shore, the lake is so shallow that a great stone dam has been built across it for the St. Gotthard railway line and the road. The chief town is Lugano, at the northern end, which by the St. Gotthard line is 19 mi. from Bellinzona, Switz., and 9 mi. from Capolago, the station at the south-eastern extremity of the lake which is only 8 mi. by rail from

BY COURTESY OF THE SWISS NATIONAL TOURIST OFFICE, NEW YORK

SAN SALVATORE PROMONTORY, LOCATED IN SWITZERLAND, AS SEEN FROM ACROSS LAKE LUGANO ON THE SWISS BANK

Como. In Italy, at the lake's southwestern extremity, a railway leads southwest from Porto Ceresio to Varese (9 mi.). Porlezza, at the east end of the lake, is 8 mi. by rail from Menaggio on Lake Como, while Ponte Tresa, at the western end, is about 13 mi. by electric railway from Luino on Lake Maggiore. The first steamer was placed on the lake in 1848.

LUGANSK (formerly **VOROSHILOVGRAD**), *oblast* of the Ukrainian Soviet Socialist Republic, U.S.S.R., was formed in 1938 and covers an area of 10,309 sq.mi. in the extreme east of the Ukraine. The Severyn (Northern) Donets cuts across the *oblast* from W.N.W. to E.S.E. North of the river is open, rolling steppe, with dry interfluvies between the valleys of the Krasnaya, Aidar and Derkul, tributaries of the Northern Donets. South of the Northern Donets are the low hills of the Donets ridge (Donetski Kryazh), originally forest-steppe, but, like the northern part, now almost wholly under the plow.

Lugansk *oblast* covers the eastern half of the industrialized Donbass or Donets Basin (*q.v.*). Population in 1959 was 2,452,172, a very high proportion (79.3%) of which was urban and lived in 24 towns and 118 urban districts, the largest being the administrative centre of Lugansk (*q.v.*; 274,520), Kadiyevka (180,205), Kommunar'sk (97,561, formerly Voroshilovsk), Krasny Luch (93,764) and Sverdlovsk (62,155) (to be distinguished from Sverdlovsk in the Ural mountains). The *oblast's* economy is overwhelmingly dominated by the great industrial area, especially its coal mining, which is the basis for much of the industrial output. There is large-scale iron and steel production, with associated heavy engineering and chemical industries. Many of the pits and factories had to be entirely rebuilt after World War II, when the Donbass was occupied by the Germans, and thus have modern equipment. Agriculture is well developed and is largely concerned with grain production, especially wheat and barley. Maize (corn), for human and animal consumption, and sunflowers are also important. There is much market gardening around the towns. (R. A. F.)

LUGANSK (**VOROSHILOVGRAD**, 1935–58), a town and *oblast*, centre of the Ukrainian Soviet Socialist Republic, U.S.S.R., stands on the Lugan river at its confluence with the Olkhovaya 420 mi. E.S.E. of Kiev. Pop. (1959) 274,520. The town dates from 1795 when a state iron foundry was established there to supply ordnance to the Black sea fleet. Lugansk grew with the development of the Donbass or Donets Basin (*q.v.*) in the 1890s and industrialization was accelerated in the 1930s. It had 20,000 inhabitants in 1895, and its present population makes it one of the largest cities of the Donbass. The major branch of its industry is heavy engineering. The former gigantic steam locomotive works, which in 1941 produced almost half the engines in the U.S.S.R., now makes diesel locomotives. Steel tubes, coal-mining equipment, tractor spares and enamelware are also made. Lugansk has a relatively small iron and steel works, most of the steel coming from other Donbass towns. It has pedagogic, agricultural and machine-building institutes and many technical schools, Ukrainian and Russian theatres, a concert hall and two museums. In World War II the town was occupied by the Germans. (R. A. F.)

LUGARD, FREDERICK JOHN DEALTRY LUGARD, 1ST BARON (1858–1945), British colonial administrator mainly associated with the development of Nigeria. He was the eldest son of the Rev. F. G. Lugard, a senior chaplain at Madras, and was born at Fort St. George, Madras, on Jan. 22, 1858. He was commissioned in the East Norfolk regiment in 1878, after only two months at the Royal Military college, Sandhurst, and joined his regiment in India. He served in the latter stages of the Afghan War (1878–80); seconded to the military transport service, he saw further fighting in the Sudan campaign (1884–85) and in Burma (1886–87) and was awarded the Distinguished Service order in 1887. While on leave from the army in May 1888 he took command of an expedition organized by British settlers in Nyasaland against Arab slave traders on Lake Nyasa and was severely wounded.

Lugard was engaged in 1889 by the Imperial British East Africa company, which had been granted a charter authorizing it to de-

velop British influence in east Africa, and in their service explored the Sabaki river region and drew up a plan under which fugitive slaves might work to earn money and so purchase their freedom. The company sent Lugard to Uganda in 1890 where he secured British predominance and, after severe fighting, put an end to the civil disturbances caused by the rivalry of the "French" (Roman Catholic) and "British" (Anglican) factions. While administering Uganda he traveled through, and mapped, large areas of the country. Returning to England in 1892, Lugard strongly opposed the contemplated abandonment of Uganda by Great Britain.

In 1894 Lugard was dispatched by the Royal Niger company to the region of Borgu, which the French government was eager to acquire. Reaching Borgu before a rival French expedition which had started before him, he secured treaties with the chiefs acknowledging the sovereignty of the company. After an expedition to Lake Ngami (1896–97) he was recalled in 1897 and sent back to west Africa to organize a local force for the protection of British interests against the French and in August raised the West African Frontier force of African soldiers led by British officers.

The differences with France were settled and after the Royal Niger company had surrendered its charter Lugard was appointed high commissioner and commander in chief of the protectorate of northern Nigeria (1900). Little of the country was under effective control but a successful campaign (mainly to put a stop to slave raiding) against the emir of Kano and the sultan of Sokoto in 1903 facilitated the effective extension of British administration. Owing to the shortage of British staff, Lugard introduced the system of indirect rule, the chiefs and officials of the native states administering their areas under the supervision of British residents. (See *NIGERIA: History*).

Resigning his office in Sept. 1906 Lugard was appointed governor of Hong Kong in April 1907; the present University of Hong Kong owes much to his initiative. He was appointed governor of both northern and southern Nigeria in 1912, with instructions to amalgamate the two administrations. This became effective on Jan. 1, 1914, and Lugard was given the title of governor general. He guided the affairs of Nigeria throughout World War I, retiring in 1919. From 1923 to 1936 he was a member of the Permanent Mandates commission of the League of Nations.

Lugard published *The Rise of Our East African Empire* (1893) which was partly autobiographical, and also wrote various valuable reports on Nigeria. His most important publication was *The Dual Mandate* (1922), a book dealing with the duties of European powers in tropical Africa. Throughout his career in Nigeria Lugard sought to ameliorate the conditions of the African people and to eliminate slavery and the slave trade.

In 1902 he married Flora Louisa Shaw who had been a distinguished writer on colonial subjects for the *Times* (London). He was knighted in 1901, was made a privy councillor in 1920 and was created a baron in 1928. He died at Abinger, Surrey, on April 11, 1945.

See Margery Perham, *Lugard, the Years of Adventure, 1858–1898* (1956), and *Lugard, the Years of Authority, 1898–1945* (1960). (A. C. Bs.)

LUGBARA (**LOGBARA**), a Sudanic-speaking people numbering about 244,000 in the 1960s. About three-quarters of them live in the West Nile district of northwestern Uganda (*q.v.*) and the remainder in the adjoining area of the Republic of the Congo. They are closely related to the Madi (*q.v.*).

Lugbara are settled agriculturalists, growing millet as the traditional staple, and much cassava and tobacco; they provide many labour migrants who work as share croppers for Ganda (*q.v.*) landowners in southern Uganda. They lack centralized political authority and what formal authority exists is exercised by rain-makers and the heads of large family groups based upon small patrilineal lineages. There are government-appointed chiefs set over large areas. The majority of Lugbara still practise ancestor worship and they believe in a creator-god, Adroa.

The Lugbara were one of the tribes of the Lado enclave, and were administered as part of the Congo Free State (later the Belgian Congo) from 1900 to 1908; then by the Sudan government until 1913 when they became part of Uganda. They are one

of the tribes least affected by modern changes among the peoples of Uganda, with a strong sense of their own identity in contrast to their Bantu-speaking neighbours to the south. See also AFRICA: *Ethnography (Anthropology): East Africa.*

See J. F. M. Middleton, *Lugbara Religion* (1960); J. P. Crazzolara, *Study of the Logbara (Ma'di) Language, Grammar and Vocabulary* (1960). (J. F. M. M.)

LUGDUNUM (**LUGUDUNUM**), a Celtic place name, possibly meaning "fort (or hill) of the god Lugos (Lug)," used by the Romans of at least four towns in or near ancient Gaul. The most important was situated at the confluence of the Rhône and Saône rivers, now Lyons (*q.v.*, for its history), and gave its name to the province of Gallia Lugdunensis. The other towns of that name are the following:

LUGDUNUM BATAVORUM, a town of the Germanic Batavi, though presumably of Celtic origin. It is commonly identified with the modern Leiden (*q.v.*) in the Netherlands, but alternative sites have been suggested on the coast near either The Hague or Katwijk.

LUGDUNUM CLAVATUM, the oldest Latin name for the modern French town of Laon (*q.v.*). By the 7th century *Lugdunum* had become *Laudunum*, hence *Laon*.

LUGDUNUM CONVENARUM, also known as **CONVENAE** (St. Bertrand de Comminges, Haute-Garonne, France). After the death of Sertorius (72 B.C.) surviving supporters of his were deported across the Pyrenees by Pompey and were settled there (*convenae*, "refugees"). The town flourished under the Roman empire. Herod Antipas and Herodias were exiled there by the emperor Caligula (A.D. 39). Guntram, king of Burgundy, sacked Convenae in 585 and it remained deserted until c. 1120, when a cathedral was built there by Bertrand de L'Isle, bishop of Comminges, after whom the present village is named.

See R. Lizop, *Les Convenae et les Consoranni* (1931).

LUGEON, MAURICE (1870–1953), French geologist, a brilliant pioneer in the development of modern Alpine geology, was born at Poissy near Paris on July 10, 1870. He moved with his parents to Lausanne, Switz., in 1876 and graduated at the university in 1893 where he later became extraordinary professor of geology and physical geography in 1898 and ordinary professor eight years later. Lugeon was closely connected with Hans Schardt's tectonic discovery of the far-traveled nature of the rocks of the Prealps that extend from Lake Geneva to Lake Thun and subsequently played the leading part in developing the tectonic ideas thus liberated and in providing a comprehensive interpretation of the Alps as a whole. In *Les grandes nappes de recouvrement des Alpes du Chablais et de la Suisse* (1901) he developed his great synthesis showing that from the Arve to Salzburg the north front of the Alpine chain is composed of large superimposed nappes. His tectonic interpretations were extended by him to regions outside the main Alpine province, notably to the Carpathians, Sicily and Morocco. Lugeon won international renown as a consultant on dam sites and published authoritative memoirs in this field: *Étude géologique sur le projet de barrage du Haut-Rhône français à Génissiat* (1912) and *Barrages et géologie* (1933). He died in Lausanne on Oct. 23, 1953. (C. E. T.)

LUGGAGE. The first piece of luggage was probably the crudely dressed pelt in which primitive man wrapped his few possessions. As man learned to use sinews, simple laced bags were evolved. Then plaiting with reeds permitted more variety of form, including rectangular baskets. Chests of wood followed; they were first dug out, later joined. Egyptian and Greek chests, some used as traveling coffers, were often beautifully painted on gesso; many were covered with leather, which overlapped the juncture of lid and body to prevent ingress of water, and strengthened with flat bands of iron. The large medieval coffer (the earliest recorded use of "trunk" is in 1462), often called a standard, usually took the form of a rectangular box with a hemihexagonal vaulted lid; it was made of thick planks of wood covered with oxhide and banded with iron in both directions. It generally had two locks and two or more handles and its weight was considerable. The lighter form of coffer with arched lid was seldom used before the 17th century. Instead of iron bands, iron or brass

corner plates gave protection, and the leather, was secured with iron or brass nails often worked into attractive patterns; often deer hide, retaining the hair, was used. More readily portable medieval luggage bore such expressive names as *gardeviance*, *clothesacke* and *mail*; none survive but they were probably essentially bags.

There was no great change until the 19th century, when there appeared trunks and cases of solid cattle hide up to $\frac{3}{4}$ in. thick. The leather trunks were later replaced by lighter and cheaper "cabin" trunks; these, made at first of compressed cane and then of compressed flax fibre, were covered with painted or proofed flax canvas and strengthened with bentwood hoops, later imitated in cheaper jute canvas and bent plywood. Toward the end of the 19th century many trunks—some, like the *Saratoga*, with trays and compartments—were made of deal covered with waste leather, painted canvas and even printed tinplate. This type was succeeded by the lighter steamer trunks of sheets of plywood covered by painted and varnished vulcanized fibre. The first wardrobe trunks also appeared at the end of the 19th century. These stood upright, some 40 in. high, one half being fitted with bars and hangers, the other with drawers.

Early bags used as luggage were made largely of leather but also of canvas and were fastened with drawcords, rods and padlocks, or iron frames. In the middle of the 19th century, when heavy leather portmanteaus were still in vogue, there appeared a series of lightweight bags made of split hide (and occasionally of crocodile or morocco leather) hung from a light mild-steel frame provided with locks and other fittings: the *Gladstone*, *Hartington* and *Rosebery* bags were familiar before World War II, as were *kit*, *brief* and *square* bags. In the third quarter of the 19th century split hide was also used, with a foundation of strawboard, for the rigid form of suitcase that lingered on to the 1940s. Shortly after 1918 the zip (slide) fastener was applied to hand luggage, revolutionizing style and design. Zip bags are now made in leather and various fabrics. In the 1920s came the soft-top case, usually covered with cotton coated with a nitrated cellulose and misnamed leather cloth; this piece was essentially a preformed cover to whose perimeter was applied a stiffening board strengthened with wire frames.

After World War II greatly increased traveling, particularly by private automobile and on airplanes that restricted the weight of luggage carried free, and the necessity of handling one's own luggage encouraged the design of lightweight but robust luggage. For this type, plywood has been used; it is bent by heat or built up over molds and covered with leather, canvas or coated fabrics, the tougher polyvinyl chloride having replaced the earlier nitrated cellulose materials. The usual cotton fabric base has been experimentally replaced by fabrics woven from plastic yarns and glass fibre. Molded forms have been employed; they were made at first of light metal alloys, later of sheets of cellulose acetate laminated with woven fabrics, and then of a "dough" of polyester resin and glass fibre: none was light, cheap or attractive, and all called for costly plant and tools. A cheaper case was made from a "dough" of polyester resin mixed with wood fibre, sometimes with a small percentage of glass fibre. These molded shells were light and inexpensive but had to be covered with coated fabrics, polyvinyl chloride sheets or leather, thus losing many of the advantages of mechanical molding. The first molded forms that dispensed with coverings were made of polypropylene as injection moldings, but the high cost of the hollow molds could be recovered only from large-scale production. This method was rendered obsolete, however, by the introduction of sheet materials that were first softened by heat and then pulled over formers by the vacuum-forming process. The material most widely used in this process in the 1960s was acrylonitrile butadiene styrene. See also **BAG**. (J. W. WA.)

LUGO, a town in northwestern Spain, capital of a province of the same name. It is situated on the Miño river 95 km. (59 mi.) S.E. of La Coruña by road. It is a commercial centre with important fairs and markets, and has slaughterhouses and meat-chilling plants. Pop. (1960) 58,264 (mun.). The Roman walls of the ancient *Lucus Augusti* remain. Houses built of granite and

slate, with *soportales* (porticoes) as a protection against the rain, predominate. There is a splendid Romanesque cathedral and San Francisco is a fine Gothic church. The town was attacked by the Normans during the middle ages. During the Peninsular War it was occupied by French troops after the withdrawal of Sir John Moore's army.

LUGO PROVINCE, one of the four comprising the region of Galicia, is bordered by the Bay of Biscay in the north, Asturias and León in the east, Orense on the south and by Pontevedra and La Coruña on the west. Area 9,803 sq.km. (3,785 sq.mi.). Pop. (1960) 479,530. The main roads are Madrid-La Coruña and Santander-Oviedo-La Coruña, and the chief rail routes are Palencia-La Coruña and Monforte de Lemos-Vigo. The province came into existence in 1833. Besides the capital, its most important cities are Mondoñedo (episcopal see), Monforte de Lemos and Vivero.

The coast line extends for 97 km. (60 mi.) from the *ría* (inlet) of Ribadeo in the east to that of Barquero in the west. It is steep and has many *rias*; the ports engage in fishing and the coasting trade. The Cantabrian mountains, with Peña Rubia (6,073 ft.), extend into the province. The Sierra de Meira divides the waters of the Sil river from the Eo. There are two hydrographic systems: the Cantabrian (Navia and Eo rivers) and Atlantic (Eume, Ulla, Miño and Sil). There are many medicinal springs. The principal sources of wealth in the province are agriculture and fishing, which together employ 80% of the population. Lugo is the main Spanish producer of rye and potatoes, but cattle and pig breeding are more important. (M. B. F.)

LUGOJ, a town and administrative centre of Lugoj district of Timișoara *regiunea* (region) in the Banat, Rum. Pop. (1960 est.) 31,670. The town lies on the banks of the Timiș river and is a rail and road centre. It is first mentioned in 1369, though a settlement there is said to date from the 13th century. Lugoj is the seat of Orthodox and Uniate bishoprics and has several old churches.

Industries include the manufacture of silk, textiles, bricks and tiles, wine and leather goods, and food processing. Lugoj was formerly divided, with a Rumanian town on the south bank and a German town on the north bank, reflecting the strong medieval German influence.

LU HSÜN (LUSIN; pseudonym of CHOU SHU-JEN) (1881-1936), Chinese writer, scholar, teacher and translator, was born of gentry stock at Shao-hsing, Chekiang. The imprisonment of his grandfather and the death of his father reduced the family circumstances when he was still a child and embittered his outlook. He matriculated at the School of Railways and Mines, Kiangnan Military academy, Nanking, and later studied western medicine, philosophy and literature in Japan on a government scholarship, returning home an ardent anti-Manchu revolutionary and a moderate cultural protectionist. In 1912 he joined the republican ministry of education, moved to Peking and devoted his leisure time to antiquarian pursuits. At the urging of friends associated with the nascent literary movement, he wrote the short story "A Madman's Diary" (1918), a pungent satire on the dark, animal forces of traditional, Confucian-oriented society. *The True Story of Ah Q* (1921) is his representative work. A mixture of humour and pathos, it is a repudiation of the old order and a classic portrayal of the national psychology. Other stories in *Call to Arms* (1923), the work that brought him national prominence, the volume *Hesitation* (1926) and the various symbolic prose-poems, reminiscences and retold classical tales all reveal a modern sensibility informed by a sardonic humour and biting satire. Although Lu Hsün is better known abroad for his works of fiction, the prose essay is more characteristic of his genius. Forced by political circumstances to flee Peking in 1926, he eventually found sanctuary in the Shanghai International settlement, where, alienated from the right and courted by the left, he turned increasingly to direct prose expression. His *Outline History of Chinese Fiction* and companion compilations of classical fiction remain standard works. Translations, largely from the Russian, also occupy a large place in his complete works. Independent, antimaterialistic and antiauthoritarian, and imbued with

a profound sense of moral justice, Lu Hsün nevertheless was adopted posthumously as the exemplar of socialist realism by the Chinese Communist movement.

CHOU TSO-JEN (1885-), eminent literary figure known for the casual, sophisticated essay, and **CHOU CHIEN-JEN** (1889-), scientist, teacher, politician and Communist governor of Chekiang province, are brothers of Lu Hsün. (W. R. Sz.)

LUHYA, a cluster of Bantu-speaking tribes in western Kenya, often known as Bantu Kavirondo; they numbered about 654,000 in the 1960s and in most parts of their country the population density is extremely high. They are agriculturalists, and provide labour migrants who are found in all parts of east Africa.

The main tribes include the Logoli, Vugusu, Nyala, Isukha, Marama, Idakho, Tiriki and Nyore. All lack traditional chieftainship, being organized into more or less politically autonomous patrilineal lineages, each associated with a stretch of land. With land shortage there has been considerable tribal interspersal. In the centre of the country are the Wanga (Hanga), the only people of Kenya with a traditional kingship. The king or chief of Wanga when the British came in the 1890s was Mumia, who sought paramountcy over the neighbouring tribes. The British supported his attempts, recognizing him as paramount until the late 1920s; but by the time he died in 1952 Wanga supremacy had dwindled. After that time, however, Luhya unity came to the fore as a political aim, with the realization of their cultural and linguistic identity as distinct from that of the neighbouring Nilotic Luo and Nilo-Hamitic Nandi, Kipsigis and Masai. See also KAVIRONDO; KENYA; AFRICA: *Ethnography (Anthropology): East Africa*.

See G. Wagner, *The Bantu of North Kavirondo*, 2 vol. (1949, 1956). (J. F. M. M.)

LUINI (LUVINI), **BERNARDINO** (fl. 1512-1532), Lombard painter, is best known for his religious frescoes. Although his fame has long been considerable, exceedingly little is known of his life, even Giorgio Vasari giving the minimum information. The earliest surviving painting certainly his work is a fresco of the "Madonna and Child" at the Cistercian monastery of Chiaravalle, near Milan. A contemporary record states that this was painted in 1512 by "B. Luino." This is also the earliest certain evidence of the painter's existence, statements concerning his birth and apprenticeship which are sometimes given as fact being derived from sources too late to be reliable. An altarpiece of the "Madonna and Child With Saints," now in the Musée Jacquemart-André, Paris, bears the inscription "Bernardin (us) Mediolanensis faciebat MDVII" and may be an early work of Luini, but the omission of the surname in the signature precludes certainty. An altarpiece of the "Lamentation Over the Dead Christ" in the church of Sta. Maria della Passione at Milan is likewise frequently, but not universally, considered an early work of Luini, but it has no signature or documentation to support it.

Between 1512 and his death in 1532 a number of paintings are signed or otherwise reliably attributed, and still others can be ascribed to Luini with confidence on the strength of resemblance to the first group. Of these numerous works, the most important among those with religious subjects are the series of paintings in the churches of S. Giorgio al Palazzo and S. Maurizio at Milan, the frescoes in the church of Sta. Maria dei Miracoli at Saronno, the two Adorations "of the Magi" and "of the Shepherds" in Como cathedral, the huge fresco of the "Crucifixion" in the church of Sta. Maria degli Angeli at Lugano and the altarpieces at San Magno, Legnano, and in the Di Rovasenda collection at Turin (from Mendrisio). Of Luini's fewer paintings of secular subjects, the most important are two series of frescoes, subsequently detached and dispersed. One of these came from the Villa Pelucca, near Monza. It consists of various mythological subjects and also some from the Old Testament. Most of the pieces are now in the Brera, Milan. The second, from Casa Rabia, Milan, is divided between the state museums, Berlin and the National Gallery of Art at Washington, D.C. The subjects are the stories of Europa and of Cephalus and Procris. Luini's work is represented in other galleries in Europe and the United States and in Canada.

The art of Luini in its entirety fits naturally into the Lombard tradition of the second half of the 15th century and the opening

years of the 16th, as exemplified by Vincenzo Foppa, Bernardino Butinone, Bernardino Zenale, Borgognone, Bramantino and Andrea Solari. To many scholars, however, one of the main points of interest is its relation to that of Leonardo da Vinci. The periods of the latter's second residence in Milan were 1506-07 and 1508-13 and while it is certain that his work was known to Luini, no evidence of personal contact is forthcoming. Although Luini, on at least one occasion, incorporated a design of Leonardo's into a painting ("Holy Family" in the Ambrosiana, Milan, from Leonardo's cartoon now at the Royal Academy, London), he showed in general greater independence with regard to the great Florentine than did most of his Milanese contemporaries. The excellence of his craftsmanship and the unstudied sweetness of his pictures were the qualities which endeared him to John Ruskin and to the later 19th century.

See Angela Ottino della Chiesa, *Bernardino Luini* (1956).

(C. H. M. G.)

LUÍS I (1838-1889), king of Portugal from 1861 to 1889, was born in Lisbon on Oct. 31, 1838, the second son of Maria II and Ferdinand of Saxe-Coburg. He was destined for the navy but the unexpected death on Nov. 11, 1861, of his brother Pedro V placed him on the throne instead. He married Maria Pia of Savoy in 1862. The reign began inauspiciously, with public disturbances and a financial crisis later aggravated by the suspension of remittances from Brazil which the Paraguayan War provoked. The overthrow of Isabella II of Spain (1868) led to agitation in favour of an Iberian union under Luis but he disavowed the idea. The king was criticized for the exercise of unconstitutional powers in attempting to control political turmoil. Republican agitation increased and republicans ran for national office in the elections of 1879. The Camões quadricentennial celebration (1880), promoted by the Freemasons, played into republican hands. In 1881 republicans aroused public opinion against the proposed treaty with Great Britain over Mozambique and India. Despite the agitation, railroads were built at home and in Africa, and the disputes with Britain over Bolama and Lourenço Marques were settled favourably by arbitration. Less satisfactory treaties were signed with France and Germany over African boundaries. Literature flourished during the reign. The king himself was artistically talented. He translated Shakespeare and works from the French. When he died in Cascais on Oct. 19, 1889, he left political problems that were to be the undoing of his successor. (M. CA.)

LUITPOLD (1821-1912), prince regent of Bavaria from 1886, was born on March 12, 1821, in Würzburg, the third son of King Louis I. By his marriage (1844) to Augusta, daughter of Leopold II of Tuscany, he had three sons and one daughter. He followed the customary military career and commanded a division in the Seven Weeks' War against Prussia (1866). On Jan. 18, 1871, he was present at the proclamation of the German empire at Versailles. Against his will he took over the regency of Bavaria in June 1886, when his nephew King Louis II was found unfit to rule; and after Louis II's tragic death a few days later he remained regent for his younger nephew Otto, who was completely insane. Luitpold's consciously patriarchal form of government soon succeeded in overcoming his people's initial mistrust. The cabinet of Johann von Lutz (prime minister since 1880) was left in office till 1890 despite its tactless handling of the royal tragedy; and Bavaria was governed strictly in accordance with liberal principles. In 1890, however, Luitpold secured a better relationship with the Roman Catholic Church, and this was further consolidated while Friedrich von Crailsheim was prime minister (1890-1903). In his dealings with the German imperial government Luitpold maintained an attitude of strict loyalty: he refrained from pursuing an actively federalist policy and did nothing to make his influence felt in foreign affairs, even though the emperor William II's methods caused him anxiety. The reform of the electoral law (1906), combined with the introduction of ministerial responsibility to parliament, made Bavaria the most democratically governed country of Germany and, in some points, even went beyond the republican Weimar constitution of 1919.

The 26 years of the regency, which lasted till Luitpold's death, were regarded as Bavaria's golden age, particularly in matters of

culture. Luitpold himself was on terms of personal friendship with many artists (e.g., Franz von Lenbach and Wilhelm Kaulbach); and though the prince regent's civil list was meagre by comparison with a king's, he spent large sums from his privy purse for the benefit of artists. He had the Künstlerhaus built as a meeting place and exhibition building, and under his rule Munich became a centre of European culture. Luitpold died in Munich on Dec. 12, 1912, and was deeply mourned. His eldest son became king as Louis III in 1913.

See F. Endres, *Prinsregent Luitpold* . . . (1916). (K. O. v. A.)

LUKE, SAINT, "the beloved physician," a companion of St. Paul (q.v.), the traditional author of the third Gospel and the Acts of the Apostles, the most literary of New Testament writers (see ACTS OF THE APOSTLES; LUKE, GOSPEL ACCORDING TO SAINT). His gentle origin is indicated by the name Loukas, a short form for the Latin Lucius or Lucanus (like Silas, Acts xv, 40, for Silvanus, I Thess. 1, 1). Possibly he was the son of a freedman of some Roman family. The Anti-Marcionite Prologue (prefixed to Luke's Gospel in some manuscripts of the Vulgate and dating perhaps from the late 2nd century), Eusebius of Caesarea and Jerome refer to him as a Syrian from Antioch. This probably means that he lived there and first met Paul there. Luke's connection with the early Antiochene church is abundantly illustrated by the detailed information he supplies in Acts (xi, 19 ff.; xiii, 1 ff.; xiv, 26-xv, 35) concerning the origin and growth of that community. Nothing is known of the time or circumstances of his conversion; if the reading of the Bezan codex in Acts xi, 28 is correct, "When we were assembled," this personal reference would indicate that Luke was an early member of the Antiochene community.

Paul calls Luke "the beloved physician" (Col. iv, 14), who undoubtedly attended the physically afflicted Apostle (II Cor. xii, 7; Gal. iv, 13-15). It can no longer be held, as it once was, that Lucan vocabulary proves that the author was a physician; however, later studies, showing that many of Luke's words formerly regarded as distinctively medical are to be found not only in medical writers but also in Josephus, Plutarch, Lucian and the Septuagint, have not done away with all the evidence. Some passages of the Marcan source that mention diseases when modified by Luke reveal the terminology and interest of a professional physician (Luke iv, 38; v, 12; viii, 44). While not proving that their author was a physician, these passages nevertheless support the tradition.

Luke accompanied Paul on his second missionary journey. The "we-sections" of Acts (see ACTS OF THE APOSTLES) recount how Luke joined Paul at Troas (c. A.D. 50) and passed over to Macedonia with him (Acts xvi, 11-12). Luke most likely remained at Philippi until the end of Paul's third mission (Passover, A.D. 58), when he joined him again as the latter set out for Troas on his return to Jerusalem (Acts xx, 5-xxi, 18). Finally, Luke accompanied Paul from Caesarea to Rome (Acts xxvii, 1-xxviii, 16). Writing from his Roman captivity, Paul refers to Luke as a "fellow worker" (Philem. 24; see Col. iv, 14) and faithful companion to the end (II Tim. iv, 11). Origen was the first to identify Luke with the "brother who is famous among all the churches for his preaching of the gospel" (II Cor. viii, 18). He seems to be the only non-Macedonian (as demanded by II Cor. ix, 2-4) of Paul's entourage eligible at the time for such identification (see Acts xx, 4).

A tradition that can be traced back to Irenaeus (c. 185) regards Luke as the author of the third Gospel. This attribution was probably also known to Justin in the middle of the 2nd century. The Muratorian canon (c. 190; see BIBLE: Canon and Text: Canon of the New Testament) ascribes both the third Gospel and Acts to Luke. The Lucan authorship of both books is generally (though not universally) accepted by modern scholars.

Luke belonged to cultivated Hellenistic circles, where he learned to write with ease good, idiomatic Greek. His writings betray an acquaintance with the historical method of his day, and the "Semitisms" that shine through his Greek style reveal a deep contact with the Greek Old Testament. In fact, his imitation of the style of the latter is at times surprising. He was a perceptive, sensitive writer with a knack for telling a story and depicting

a scene, and his Gospel has been described as "the most beautiful book" ever written. His two books constitute the earliest history of the Christian church.

The Anti-Marcionite Prologue records that Luke wrote his Gospel in Greece, was not married and died in Boeotia (or Bithynia?) at the age of 84. But further details about his life come from either later traditions or legends; e.g., that he was martyred, that he was one of the Seventy (Luke x, 1), that he was the unnamed disciple of Emmaus (Luke xxiv, 13-35), that he was a painter.

Luke is the patron of physicians and artists; in the Roman martyrology his feast day is Oct. 18. His symbol is an ox, the sacrificial animal, because his Gospel begins with the story of Zechariah, the priest, the father of John the Baptist.

Fr.)

LUKE, GOSPEL ACCORDING TO SAINT, the third Gospel of the New Testament. It is the first volume of a longer work which the author addressed to the same patron, Theophilus; another New Testament book, the Acts of the Apostles (q.v.), is the additional volume.

Sources.—As the third of the three Synoptic Gospels the Gospel of Luke is closely related to Matthew and Mark; like Matthew it is based on the Marcan narrative and it also uses Matthew's Saying-Source Q (see MARK, GOSPEL ACCORDING TO SAINT; GOSPELS). In addition to these, Luke employs at least one other source which contained traditions unknown to Matthew and Mark, thereby preserving in his Gospel the following unique materials:

Luke i, 1-80:	promise of the Baptist's birth, annunciation, visitation, "Magnificat," birth of the Baptist, "Benedictus"
ii, 1-52:	nativity of Jesus, circumcision and presentation in the Temple, Jesus at 12 years
iii, 10-14:	John's sociological teaching
iv, 16-30:	first preaching in Nazareth
v, 1-11:	Peter's draught of fishes
vi, 24-26:	woes to the wealthy
vii, 11-17:	the widow's son at Nain
vii, 36-50:	the woman who was a sinner (41-43: parable of the two debtors)
viii, 1-3:	the ministering women
ix, 51-56:	the inhospitable Samaritans
x, 1, 17-20:	sending and return of the Seventy
x, 29-37:	parable of the good Samaritan
x, 38-42:	Martha and Mary
xi, 5-13:	parable of the friend at midnight
xi, 27-28:	the blessedness of Christ's mother
xii, 13-21:	parable of the rich fool
xii, 47-48:	parable of punishment and responsibility
xiii, 1-9:	call to repentance and parable of the fig tree
xiii, 10-17:	Sabbath healing of the bent woman
xiii, 31-33:	Jesus and Herod (leaving Galilee)
xiv, 1-6:	Sabbath healing of the man with dropsy
xiv, 7-14:	discourse at the banquet
xiv, 28-32:	parables of the architect and the king
xv, 8-32:	parables of the lost coin, and the prodigal son
xvi, 1-31:	parables of the unjust steward, and Dives and Lazarus
xvii, 7-10:	parable of the servant's wages
xvii, 11-19:	healing of the ten lepers
xvii, 20-21:	on the coming of the Kingdom
xviii, 1-14:	parables of the unjust judge, and the Pharisee and the publican
xix, 1-10:	Zacchaeus
xxi, 15-38:	special account of the Lord's Supper, and last words to the disciples
xxiii, 27-32:	words on the road to Calvary
xxiii, 39-43:	the two crucified criminals
xxiv, 13-35:	the road to Emmaus
xxiv, 36-49:	the appearance in Jerusalem
xxiv, 50-53:	the Ascension

The character of the source for this special Lucan material is debated. But whether there was actually a Proto-Lucan Gospel, or only a number of written "collections" (of parables, infancy nar-

ratives, resurrection accounts), the peculiarities of arrangement and outline of the present Gospel certainly are the work of its author, who impressed his own literary skill and theological insight upon the various sources used by him.

Style and Technique of Composition.—Luke is a writer of distinctive qualities of mind and style. Though he shares with other New Testament writings the vernacular flavour of 1st-century Greek, his language is more literary than that of his sources. He repeatedly improves Mark's wording, and also avoids foreign words, whether Latin or Aramaic, used by his sources.

Luke connects single narratives much more smoothly than does either Mark or Matthew; he sometimes localizes two scenes in the same setting (e.g., v, 29-32 and 33-38), often establishes a temporal sequence and frequently employs connecting participle constructions. But Luke also realizes that a monotonous sequence of single stories would result in a rather unconvincing picture of Jesus' life. He therefore makes single incidents appear as illustrations of the whole of a continuous history; this purpose is served by the frequent introductory phrase "(and) it came to pass (when) . . ." (Authorized Version), often connected with a date.

For purposes of division or connection he formulates summary statements (i, 80, etc.), a specifically Lucan device also employed in Acts (e.g., ii, 42-47). Significant for Luke as a historian is his attempt to relate the history of Jesus to world history (i, 5; ii, 1-3; iii, 1-2; xxiii, 6-7).

A characteristic of the Gospel is Luke's intermittent use of sources in the following way (Q = synoptic Saying-Source; S = special Lucan sources; minor deviations are not mentioned):

Luke i, 5-ii, 52:	S
iii, 1-iv, 30:	synthesized from Mark, Q and S
iv, 31-vi, 19:	Mark (insertions from S)
vi, 20-viii, 3:	Q (insertions from S)
viii, 4-ix, 50:	Mark
ix, 51-xiii, 30:	Q (insertions from S)
xiii, 31-xviii, 14:	S (insertions from Q)
xviii, 15-xxiv, 11:	Mark (insertions from Q and S)
xxiv, 13-53:	S

Thus, introduction (birth narrative) and conclusion (Resurrection appearances) are taken from special sources, whereas the body of the Gospel (iii, 1-xxiv, 11) retains the Marcan structure. But a large central section, the "travel narrative" (ix, 51-xviii, 14), is composed almost entirely on the basis of Q and S, without any use of Mark. Luke, however, adds and omits, rearranges and reinterprets the source material whenever necessary to express his own theological evaluation of Jesus' history.

Luke's View of History.—Luke, who in the manner of a Greek historian introduces his Gospel with a preface (i, 1-4), is the first to conceive of the life of Jesus as a revelation pertaining to a former period of an ongoing history. Thereby the early Christian twofold eschatological scheme of "this age and the age to come," within which Mark had understood the Jesus event as the eschatological turning point of the two ages, is replaced in Luke by a tripartite view of history in which the time of Jesus is the centre rather than the end. Luke's Gospel presents Jesus' life as this centre of history in its relation to the preceding period, the time of the Law and the Prophets, and to the following period, the time of the church, in the following way:

Luke i, 5-iv, 13:	the end of the prophetic era as preparation for the revelation
iv, 14-xxii, 2:	the revelation in Jesus' ministry as the centre of time
xxii, 3-xxiv, 53:	the beginning of the time of the church in Jesus' Passion and Resurrection

The beginning of the central period is marked by the departure of Satan after the temptation (iv, 13). The Baptist still belongs to the former period of the Prophets (xvi, 16), preaching only the "baptism of repentance" (iii, 3), but not the coming of the Kingdom (as in Matt. iii, 2). His imprisonment is told before Jesus' appearance, and he is not mentioned at Jesus' baptism (compare Luke iii, 21 with Mark i, 9).

The end of Jesus' ministry does not look forward to the end of the world and time (as in Mark xiii), but to the next period of history, the time of the church, which actually begins with the return of Satan at the beginning of the Passion of Jesus (Luke

xix, 3). It will be a time of temptation and suffering, as it is prefigured in Jesus' Passion, but it remains part of the ongoing history, and Luke repeatedly warns against mistaking events of this history as signs of the end—neither Jesus' Passion (xvii, 20–25), nor his Resurrection (Acts i, 4–11), nor the fall of Jerusalem (compare Luke xxi, 20–24 with Mark xiii, 14–20).

As a result the Gospel of Luke rightly can be understood as containing the proper conclusion of the Old Testament in its first chapters, whereas the last chapters have their direct continuation in the Acts of the Apostles (compare Luke xxiv, 49–53 with Acts i, 4–11 and ii, 1–31). The life of Jesus itself, as the time without Satan and without temptation, is the period of revelation and the sacred centre of history.

Geographical Scheme.—Corresponding to this historical structure of the Gospel is a certain geographical scheme used as a meaningful device of theological characterization.

1. The end of the prophetic period is closely connected with the sacred places of the Jewish people: Jerusalem (ii, 22, 41), Bethlehem (ii, 4, 11), the Jordan (iii, 3; iv, 1), the wilderness (iii, 2; iv, 2).

2. Jesus' ministry as the central period of history is limited to Jewish districts, Galilee and Judaea (*see especially* xxiii, 5), which Jesus never leaves during his ministry, neither for Samaria (xx, 51–56) nor for the surrounding gentile country (compare Luke ix, 18 with Mark viii, 27). He also avoids the sacred places of the prophetic period, except in the Temple ministry, and even on this occasion Luke does not say that Jesus entered the city of Jerusalem itself (compare Luke xix, 45 with Mark xi, 11, 12).

3. The beginning of the church era, however, is closely connected with Jerusalem, the place of Jesus' Passion and death (*see* xiii, 33). In contradiction to Mark and Matthew, Luke presents no Resurrection appearance in Galilee but only in and around Jerusalem (xxiv, 13 ff., 33, 36 ff.; compare Luke xxiv, 6 with Mark xvi, 7). There also the disciples witness the Ascension (xxiv, 50–53) and there they are to wait for the sending of the Spirit (xxiv, 49; Acts i, 4). Thus Jerusalem, the Holy City and centre of prophecy, also becomes the birthplace of the church.

Similarly, Luke's geographical details have special significance. He bypasses the Sea of Galilee as the centre of Jesus' early ministry and preaching (Luke viii, 4 omits the "sea" when reproducing Mark iv, 1), for example, and refers to it as a "lake" (of Gennesaret) where messianic epiphanies occur (Luke v, 1–11; vii, 22–25). In a similar way, "the mountain" is omitted in the temptation (iv, 5; compare Matt. iv, 8) and in the Lucan parallel to the Sermon on the Mount (Luke vi, 12–17; compare Matt. v, 1), and exclusively designates the place of revelations and prayer (vi, 12, etc.).

Obviously such a reconstruction of the locality often is in contradiction to traditional information, and sometimes is geographically quite improbable. But Luke looks upon Palestine as the "Holy Country" of Jesus' sacred history, and, therefore, the primary significance of the locality is theological.

Jesus' Ministry as the Centre of Time.—This is portrayed by Luke in three phases:

Luke iv, 14–ix, 50:	wandering in Galilee and Judaea
ix, 51–xix, 27:	traveling through Galilee and Judaea to Jerusalem
xix, 28–xxii, 2:	the Temple ministry

In the first phase Jesus is wandering about like an itinerant Christian missionary, driven by the Holy Spirit (iv, 14; compare Acts xiii, 2 and *passim*). Jesus' works—no longer understood as the manifestation of the eschatological battle with Satan (*see* MARK, GOSPEL ACCORDING TO SAINT)—are attestations of his divine authorization (*see* Acts ii, 22). They always precede the "way" as distinguished from that of the Pharisees and the Baptist (ix, 30–39, etc.). The main purpose of this section is to assemble the call of foreigners (v, 1–11, 27–28; vi, 12–16), and the substitution for Jesus' family of all those who "hear the word of God" (viii, 19–21). But the disciples who recognize Jesus as the "Christ of God" (ix, 20) witness the messianic epiphanies

(viii, 22–25; ix, 28–36), receive the authority of healing and preaching (ix, 1–2) and are introduced to the necessity of suffering (ix, 22–27).

In the second phase the location (Galilee and Judaea) and the general structure of Jesus' ministry ("acting and preaching") are retained; this section also begins with a "rejection" (ix, 51–56; compare iv, 16–30). But there are several new elements. Jesus is now traveling to a certain goal—Jerusalem (ix, 51, etc.). He repeatedly turns to his disciples with special instruction, especially discourses about the time of the church, whereas to "those outside" Jesus speaks only in parables (*e.g.*, xii, 13–21; compare xii, 1–12 and 22 ff.). Halfhearted followers are rebuked, especially by Jesus' demand to give up wealth, and any missionary emphasis is completely absent. Jesus is now the Messiah who decidedly travels toward his destination; who consciously faces the necessity of his suffering as the fulfillment of prophecy (xviii, 31 as compared with Mark x, 33); who is already watched by those who will kill him, the Pharisees and lawyers, who are always nearby, offended by his behaviour and discussing his authority (xi, 25–37, etc.).

In the last phase the centre of Jesus' activity is the Temple, into which he enters upon arrival from Jericho, and the Mount of Olives. Preaching in the Temple, he is surrounded by three groups: (1) the people with their meaningless appreciation; (2) the leaders of Jerusalem who try to find an opportunity to destroy him; (3) the disciples who learn to distinguish between the historical event of the fall of Jerusalem and the eschatological events that bring time and history to a definite end (xxi, 5–36; compare Mark xiii, 1–37).

The Temple ministry as an exemplary description of the situation of a Christian missionary concludes the time of revelation. The Passion and Crucifixion of Jesus portray the typical death of a martyr, but according to Luke they do not have a special meaning for salvation. It is the opening chapter of the history of the church—a period without the presence of Jesus, but under the guidance of the Holy Spirit.

Literary History.—The author of the third Gospel (and of Acts) was, according to the tradition, Luke the physician and associate of Paul (Philem. 24; Col. iv, 14; *see* LUKE, SAINT). This tradition encounters major difficulties in Acts, since the contradictions between Acts' narratives about Paul and Paul's own letters should not have arisen if the author had actually been Paul's assistant (*see* ACTS OF THE APOSTLES). In any case, the Gospel was written by a man who knew about Jesus only through traditions of the church and written sources. Whether he was a Jewish Hellenist or a gentile by birth, his Greek style and vocabulary were as educated as that of such Greek writers as Xenophon, and he lived in a time for which not only the life of Jesus but also the "apostolic age" belonged to past history. Since the Gospel of Mark is also used, and the prophecy in Luke xxi apparently reflects the actual fulfillment in the year A.D. 70, the last two decades of the 1st century A.D. are probably the best date; some scholars even prefer the beginning of the 2nd century A.D., since neither the Gospel nor Acts was used before II Clement, Justin and the heretic Marcion.

About the place of writing, nothing can be said with certainty. If Luke's geographical picture of Palestine is really incorrect, it is more likely that he wrote in Asia Minor or Greece than in Syria. Nor is anything known about Theophilus, to whom both Gospel and Acts are addressed. *See also* BIBLE.

(H. H. Ko.)

LULEÅ, a city and seaport of Sweden, seat of a Lutheran bishop and capital of the *län* (county) of Norrbotten, is located at the mouth of the Luleälv where it enters the Gulf of Bothnia, 724 km. (450 mi.) N.N.E. of Stockholm. Pop. (1960) 30,488. Buildings of interest include the Gammelstad church (c. 1400), the cathedral (1894) and the provincial museum. Luleå is linked by rail with Stockholm, Narvik, Nor., and Tornio, Fin., and by air with Stockholm and Kiruna. The principal industries include ironworks, shipbuilding, engineering and wood pulp. The port, ice-bound in winter, exports chiefly iron, iron ore, timber and pulp and imports coal, oil and gasoline. Founded in 1621 by Gustavus Adolphus 7 mi. farther up the river, Luleå was moved to its present site in 1649. It was almost entirely destroyed by fire in 1887.

LULEÄLV (LULE RIVER), in northern Sweden, flows south-east from the Norwegian frontier to the Gulf of Bothnia at Luleå. Total length 450 km. (279 mi.). There are two main headstreams, the Stora Luleälv and Lilla Luleälv; Sareks National park in the interfluvium rises to 6,857 ft. at Sarektjåkko. The headstreams have numerous lakes, some of which are dammed to increase storage for hydroelectricity production. The river has several high falls. Porjus is one of the chief power stations, supplying the nearby iron mines and railway and feeding power south via Harsprånget. Luleå (q.v.); with its outport, Svartösten, is the main port and handles iron-ore exports in summer. (A. C. O'D.)

LULL (LULLY), RAMON (RAYMOND): see LULL, RAMON.

LULLY, JEAN BAPTISTE (GIOVANNI BATTISTA LULLI) (1632–1687), French court and operatic composer. Born in Florence of Italian parents on Nov. 28, 1632, he changed his name to its French form when he became a naturalized Frenchman. His early history is obscure but it is probable that he was taken to France by the duke of Guise. He entered the service of Mme de Montpensier and became a member of her string band, but was dismissed for having composed some scurrilous verses and music. He joined the court band of Louis XIV in 1652 as a violinist and soon became composer of dance music to the king and leader of the newly formed *Petit Violons*. In 1658 he began to compose music for the court ballets and from 1662 to 1671 he collaborated with Molière in such works as *Les Fâcheux*, *Le Mariage forcé*, *La Princesse d'Élide* and *Le Bourgeois Gentilhomme*. From 1672 until the time of his death he worked with the librettist Philippe Quinault. The subjects of the works produced by this partnership vary from the classical *Atys* (1676) and *Isis* (1677) to the heroic *Roland* (1685) and the pastoral *Le Temple de la Paix* (1685). Lully died in Paris on March 22, 1687, from blood poisoning resulting from a wound in his foot caused by his long conducting stick.

A man of insatiable ambition, his rise from violinist in Louis XIV's court band was meteoric and was accomplished by brazen and merciless intrigue. By 1662 he had gained complete control of the court music by the following royal appointments: *Brevet de la charge de Composition de la Musique de la chambre du Roi* in 1661 and *La charge de Maître de Musique de la Famille royale* in 1662. He then acquired from Abbé Perrin and Robert Cambert their patents of operatic production, and by 1674 no opera could be performed anywhere in France without Lully's permission. In 1681 he received his *lettres de nationalisation* and his *lettres de noblesse*. He also became one of the *secrétaires du roi*, a privilege usually held only by the French aristocracy.

At the outset of his career Lully's operatic style was similar to that of the Italian masters P. F. Cavalli and L. Rossi. He quickly assimilated the contemporary French idiom, however, and then created a new and original style of writing that was widely imitated in Europe. In his ballets he introduced new dances such as the minuet and made use of a higher proportion of quicker ones such as the *bourrée*, *gavotte* and *gigue*; he also introduced women dancers to the stage. The texts in both ballets and operas were French.

He established the form of the French overture and abandoned the *recitativo secco* style. This last he replaced by an accompanied recitative of great rhythmic freedom with careful word set-

ting, and declamation. This led to a lessening of the demarcation between the recitative and the aria, so that French opera acquired much more continuity. The arias themselves, however, retain many Italian characteristics. Each is written in a particular style and mood: *chanson à couplets*, *air-complainte* (*arioso*) and *air déclamé*. His operas frequently end with a chaconne movement and in this he was followed by both Rameau and Gluck.

Among Lully's other works are several sacred compositions, including the famous *Miserere* and 17 motets; dances for various instruments; suites for trumpets and strings, a form that became very popular in England during the Restoration; and the *Suites de Symphonies et Trios*. (C. A. L.)

LUMBAGO, a sprain of the back, characterized by pain, muscle spasm and limited motion. See SPINE, DISEASES AND DISABILITIES OF.

LUMBERING, a broad term that designates the production and marketing of lumber and certain other forest products. Lumbering production generally is understood to include harvesting (logging) the raw material and converting it into marketable forms.

About two-thirds of the annual world lumbering output consists of fuel wood, pulpwood, pit props and similar items. The other one-third is comprised of saw logs, plywood, railroad ties and similar sawed products; it is to this second group that the term lumber, or timber in Britain, is applied.

The annual world production of sawed wood (i.e., lumber) is estimated to be about 140,000,000,000 bd.ft. The leading lumber-producing countries, and the approximate percentages of world production they account for, are: U.S.S.R. 32%, United States 24%, Japan 8%, Canada 5%, Sweden 2½%, Finland 2½%, West Germany 2%, France 2%, Norway 2%, Brazil 2%, Austria 1½% and Australia 1%. Other producers of significant amounts of lumber are Poland, Czechoslovakia, Rumania, East Germany, Yugoslavia, New Zealand, Italy, Spain, the United Kingdom, Indonesia, Mexico and the Philippines. About 80% of the world's lumber is produced from softwood (coniferous) species while 20% is derived from hardwoods (broad-leaved deciduous species).

This article discusses (1) the general methods of lumbering and (2) the lumbering industries in the major producing regions and countries. Information about the propagation, management and conservation of forests is included in FORESTS AND FORESTRY. Supplemental information about production will be found in the separate articles on the producing countries (e.g., CANADA) or their political subdivisions (e.g., BRITISH COLUMBIA).

Other articles related to lumbering are COOPERAGE; NAVAL STORES; PAPER MANUFACTURE; PAPERBOARD; PLYWOOD; TURPENTINE.

Logging.—The methods of felling trees and converting them into logs are generally the same in all forested regions. First the tree is undercut with an ax or a power saw on the side of the fall. A two-man crosscut saw or a power saw is employed opposite the undercut. Where the ground is flat, the men cut from the ground; but where the ground is rough or sloping and irregular, or where the trunk of the tree is heavily buttressed, the undercutting and sawing are done from a platform or springboard.

After felling, branches are trimmed off and the tree is sawed off bucked into logs of a length convenient for handling. After bucking, the logs are dragged or skidded to concentration points, usually with either power skidders or tractors and log arches. Where steel cables are employed over valleys and canyons, the method is called high-lead skidding. Other methods are overhead skidding (the logs are hoisted up over the brush and ground for some distance) and ground-line skidding, which is the dragging of the log over the ground by means of a cable. In Scandinavian countries horses and motor trucks are frequently used for transporting the logs to rivers, where they are subsequently floated to the mills. In Burma the elephant is used; in many tropical forests manual labour is often the only means of hauling the felled log to the nearest roadway.

In the U.S. northwest a spar tree is frequently employed in the skidding operations. This tree is selected for its height and favour-

able location with regard to the surrounding trees to be felled. A man known as a high-climber ascends the tree, aided by climbing spurs affixed to his shoes and a rope around the tree. He is equipped with a saw and an ax, and as he ascends he cuts off interfering branches until he reaches the desired height, which is usually about 175 to 200 ft. and about 30 to 50 ft. from the treetop. Then he saws off the top, waits until the swaying caused by the top's rebound has stopped and descends. The rigger next ascends, carrying equipment for rigging. Finally the spar is rigged at the top with cable and pulleys and a loading boom is affixed about 20 ft. above the ground. A cable with grab hooks on the end is carried to the log to be skidded and then, by means of a steam or electric skidder, the log is dragged within reach of the loading boom, which raises the log off the ground and loads it on a nearby truck or railroad car or stacks it for future loading. When the logs reach the mill centres they are stored in log ponds, which usually cover a number of acres. They are kept there until ready for manufacture. The ponds facilitate sorting and cleaning and also prevent the deterioration that would occur if the logs were left on the ground for any appreciable length of time.

Sawmill Operations.—Sawmills vary widely in size. The largest plants, employing several thousand persons, and the smallest, operated by fewer than a dozen men, often coexist in the same region. Large-scale operations offer no decisive competitive advantage; moreover, the small capital investment required (about \$10,000 in the U.S. for the average rotary sawmill) facilitates entry into the business. A group of farmers living in a wooded area may operate a sawmill part time.

In the U.S. the number of small mills grew rapidly early in the 20th century as lumber prices increased and second-growth timber became available in all parts of the nation. In 1900 large and medium-sized mills (i.e., with an annual output of at least 10,000,000 bd.ft.) accounted for most of the U.S. production. By 1960 small mills produced nearly two-thirds of the total.

Most modern sawmills employ the same general type of machinery and somewhat similar plant layouts. Band saws of varying types such as single-cut, double-cut, vertical and horizontal band resaws and gang saws are common in the larger mills. Many labour-saving devices are employed. Various types of conveyers and other machinery permit the log to enter the mill and pass out as manufactured lumber, with little handling or moving by hand. The modern methods of lumber manufacture are so intricate and so efficient as a rule that the term sawmill has been supplanted in some measure by that of forest-products manufacturing plant.

The following method of lumber manufacturing is prevalent, with variations to fit certain local requirements. The logs enter the head mill from the pond over an inclined chute or log slip. They are transported by an endless spiked conveyer known as a jack ladder or bull chain. As logs ascend the slip they are sprayed with water to remove grit and dirt that might dull the saws. Hydraulic log debarkers are installed at larger mills to strip the logs of bark prior to sawing. Sawmill refuse (slabs, edgings and trimmings) free of bark can then be utilized for making fibreboard and the like. From the slip the jack ladder carries the log under a large circular saw known as the deck saw, which is used if the log is to be shortened; otherwise the log is "kicked" off onto the log deck by steam-driven steel arms. From the log deck the log rolls onto the log carriage. A steam or air nigger (mechanically operated steel arms) helps to place the log in the proper position. The carriage is a long, flat platform that is made to travel back and forth rapidly on a track, keeping the log against a band or head saw that squares it and reduces it into flitches or cants. The log is turned from time to time on the carriage by means of the nigger. If the log is to be used as a timber, it is squared and edged and passed immediately to the rear of the mill, where the timber dock is usually located. If the log is to be converted into lumber, the flitches or cants enter the remanufacturing plant directly behind the head mill, where they pass to the gang saws and edgers and then to the trimmers.

Several types of headsaws (main saws) may be used. Large circular saws are common in small and medium-sized mills but band saws are preferred in large establishments. A band saw con-

sists of a continuous band of steel with teeth on both edges; the band moves at extremely high speed around two large broad-rimmed wheels. One wheel, a type of heavy cast-iron flywheel, commonly is mounted under the floor and the other is mounted above the sawing area. Large band saws measure about 50 ft. long and 15 in. wide. The teeth on large double-cut band saws must be sharpened after the saw has been used for about four hours. When the saw becomes dull, it is hoisted to the saw filing room, where the teeth are first swaged (i.e., square, sharp corners are put on the worn points of the teeth) and shaped to the proper angle and width, and then sharpened by automatic filers. Some North American and many European sawmills use gang saws, which consist of as many as 40 parallel saws arranged in a movable sash mounted in a heavy iron frame. The logs are first slabbed into square cants by a circular or band headrig. The cants, either singly or in groups, are then passed through the gang saw and in a single trip are converted to lumber of the desired thickness. Gang saws produce a large volume of smoothly sawed lumber with less labour than required with other types of saws. The main disadvantage of the gang saw is that the log cannot be turned, nor can the thickness of the cut be varied.

A system of rollers carries the boards from the headrig to the edger, where bark, wane and uneven edges are removed and wide boards are cut to standard widths. Several circular saws, one fixed and one movable, perform this function. The boards are next carried sideways to the trimmer. Here a battery of spinning saws suspended 24 in. apart over the conveyer are operated by a trimmer man to remove decay, cracks, jagged edges or other defects. As the operator manipulates a keyboard of levers, the saws drop alone or in combinations to trim the boards in a manner that produces the maximum amount of good lumber of uniform standard length and with square ends. (See also SAWMILL; WOODWORKING MACHINERY.)

Grading.—The trimmed boards then travel down a ramp to the greenchain, a waist-high conveyer, to be sorted by species, thickness, length, weight, width and grade. The greenchain is situated either in a shed with open sides or in a separate building. Workmen standing at either side of the head of the greenchain mark each board with a coloured pencil. The sorted lumber is piled in bunks or bins. When a bin is filled, an overhead crane or a straddle truck lifts the entire stack and carries it to the yard for storing or to the kiln for drying.

Lumber is graded on the basis of the number, location and type of knots and other defects, and according to intended use. Thus, in the U.S., shop grades are designated for manufacture into sash, doors and other woodwork. Common grades 1, 2, 3, 4 and 5 are general utility lumber suitable for such uses as roofing and framing, while the select grades of A, B, C and D may be used when paint or other finishes will be applied.

Grading practices conform to rules adopted by regional trade associations and in some countries these are enforced by a system of inspection. At one time each mill followed its own rules. The confusion caused by the differences in sizes, grades and specifications led to attempts to simplify and standardize grades. In the U.S. lumbermen in the Great Lakes area achieved considerable success in the standardization of grading and their standards were later adopted in other regions; in the 1920s the so-called American Lumber Standards were adopted to serve as a guide for rules formulated regionally for each major species.

In its modern concept the term lumber is restricted to include only those products of the saw not further manufactured other than by being sawed, resawed, passed lengthwise through a standard planing machine, crosscut to specific lengths and matched. Lumber includes deals, battens, boards, planks, structural timbers, scantlings, sawed crossties, flooring and dimension and pattern stocks, all measured in board feet, cubic feet, cubic metres and standards (1 Petersburg standard = 165 cu.ft. or 1,980 bd.ft.).

In North America lumber is classified as boards, dimension or timbers, depending on thickness. Boards are less than 2 in. thick. All boards are thinner than their nominal thickness. A 1-in. board, for example, is dressed to a minimum thickness of 25/32 in. The same is true for the thickness of dimension lumber, which is 2 in.

or more but less than 5 in. thick. Two-inch dimension lumber may be dressed to 1½ in. A piece of 2 by 4 dimension, therefore, may measure 1½ in. by 3½ in. Joists, planks and other structural sizes are classified as dimension. Timbers are 5 in. or more in thickness and width. The retail selling price of lumber is reckoned on the basis of 1,000 bd.ft. A board foot, the unit of measure used by the U.S. lumber industry, represents a volume of lumber 1 in. thick and 12 in. in width and length (424 bd.ft. = 1 cu.m.; 1,980 bd.ft. = 1 standard; 12 bd.ft. = 1 cu.ft.). Some items such as molding are sold by the lineal foot, while plywood and fibreboard are sold by the square foot.

Drying.—If wood is used in construction without being dried properly it will shrink or swell and has a tendency to warp or split. Dry lumber retains relatively stable dimensions and in addition is stronger, substantially lighter in weight and less vulnerable to decay than moist lumber.

The most common method of drying lumber is that of air seasoning; i.e., piling lumber outdoors to dry. The lumber is stacked in courses or layers on foundation piers so that each surface receives maximum exposure to air currents. Narrow strips of boards, called stickers, are laid crosswise over each layer and spaces are left between the boards to allow the air to circulate. The tall piles are sloped and roofed to protect the lumber and permit water drainage. After 6 to 18 months the seasoned lumber is removed from the yard, graded again, finished, then stored until shipped.

To accelerate the drying process and permit greater control of temperature and humidity, lumber is kiln-dried. The result, aside from reducing the drying time to about one week, compared with an average of one year for air seasoning, is a better product. In practice the two methods are used together; to reduce costs, green lumber may be air seasoned before being kiln-dried.

A dry kiln is a shedlike building in which temperature, humidity and ventilation are automatically maintained at levels that vary according to the size, species and moisture content of the lumber being dried. Proper stacking and circulation of air insure uniform drying. Forced ventilation by fans has replaced natural drafts in the kilns. Heat is provided by coiled tubing filled with steam from boilers fired by sawdust, bark and other mill refuse. The optimum temperature and other conditions for the various stages of the drying process are known for each species and size of wood. Samples are cut from the wood at intervals as it is kilned and are tested in order to check quality and moisture content.

A development called vapour seasoning reduces the drying time to about 7 to 12 hours. Green or partially seasoned wood is placed in a vacuum chamber and subjected to high temperatures that cause the moisture in the wood to vapourize rapidly.

Kiln-drying, together with motorized log transportation and heated log storage ponds at sawmill plants, has practically made the lumber industry independent of the weather in cold climates. The various operations involved in lumbering, from cutting the trees to marketing the finished product, can now be conducted on a year-round basis. Early-day lumberjacks in the United States harvested trees in the winter logging season, when the logs could be hauled by sleigh to the banks of the nearest frozen stream. During the driving season in the spring, the rivers, swollen by water from melting snow, carried the logs down to the sawmills, where they were stored in log ponds. The sawing season began in April and lasted until the log ponds froze or until there was no more piling room in the yard. The green (moisture-laden) lumber was piled up to dry or season in the open air. Many months later the seasoned lumber would be ready for market. Altogether, about two years elapsed from stump to market. In some areas of the world, notably in the Scandinavian countries and Finland, and to some extent in North America, lumbering is still conducted by the season, with sleigh hauling in winter, spring drives and summer sawing. Nevertheless, in all lumber-producing regions the practice of kiln-drying has proved advantageous in reducing the storage period and the risk of deterioration in quality, and in permitting more accurate control of the moisture content.

The Finishing Process.—Dried rough lumber is further processed in a planing mill, where sharp knives revolving at high speed shave the lumber and give it a silky, smooth surface. A planer and

matcher, the basic unit in a planing mill, surfaces the two sides and two edges of each piece of lumber. Various profile attachments and cutterheads shape the lumber into window sash, furniture components and materials for countless other uses. Molding is turned out by special molding machines. Assorted devices, including horizontal and vertical resaws, are installed as adjuncts either to the sawmill or planing mill, or both, to salvage usable material from slabs, miscuts and large pieces cut off by the trimmers and edgers, or to produce shiplap, flooring, siding, etc.

United States.—About one-third of the United States is forested, and 489,000,000 ac. are accessible and capable of growing commercially valuable timber. Another 297,000,000 ac. are classified as noncommercial. More than 132,000,000,000 bd.ft. of wood are harvested annually for all purposes, an amount that is balanced by new growth. The rapidly growing southern forests account for more than half the total production; however, Oregon, Washington and California are the top producing states, followed by Alabama, Mississippi, Texas, Arkansas, North Carolina, Louisiana and Georgia. The principal southern stands are made up of pines, cypress and white cedar mixed with hardwoods. The central region, embracing the middle Mississippi and Ohio river valleys and part of New England, yields oak, hickory, ash, elm, walnut, beech, maple and other hardwoods. In the northern forest, from Maine to Minnesota, white, red and jack pines, spruce and hemlock softwoods and maple, birch, aspen and other hardwoods predominate. West of the eastern slopes of the Rockies is the major source of softwood sawtimber, including ponderosa, sugar, white and lodgepole pines, Douglas fir, western larch, Sitka and Engelmann spruce, white fir, red cedar and California redwood.

The production of lumber in the U.S. totals about 31,500,000,000 bd.ft. annually, of which about 85% is from softwoods and 15% from hardwoods. The major softwoods are Douglas fir and Southern yellow pine, which account respectively for about 37% and 22% of the lumber manufactured from conifers. Other leading softwood lumber species are ponderosa pine, white fir, hemlock and redwood. By far the most important hardwoods for lumber are the oaks, which account for about 70% of the production in that category. Other major hardwoods used for lumber are yellow poplar, maple, sweet gum (red and sap), tupelo and black gum, beech, elm, birch, cottonwood and ash.

During the North American pioneer era wood was abundant, cheap and indispensable. Houses, barns, town halls, schools, churches, stores, saloons and virtually all other conceivable structures—including sidewalks and streets—were made of wood. Goods sold in the market were packed in wooden barrels, casks, kegs, boxes and crates. Wood was the principal fuel.

Large-scale lumbering began in Maine during the colonial era. As the population grew and settlers penetrated inland, the lumber industry expanded and moved steadily westward. Before 1850 the industry was centred in New York and Pennsylvania. During the next half century the pine forests of the lake states (Michigan, Wisconsin and Minnesota) were felled by the double-bitted ax and crosscut saws of the woodsmen as they laboured to fulfill the tremendous demand for lumber from the newly settled treeless prairies and plains. About 1895 a market was developed for southern longleaf and shortleaf yellow pine, until then virtually untouched. After 1900 the industry pushed rapidly to the Pacific northwest. By the 1960s lumber was produced from coast to coast and from border to border. About 57,000 companies operated 46,000 sawmills, 1,150 pulp, paper and paperboard plants, 300 plywood and veneer mills and 200 cooperage mills; these mills, which employed approximately 1,600,000 persons, produced 30% of the world's lumber and more than 40% of the world output of other forest products, excluding fuelwood.

U.S. production of lumber in the early 1960s totaled about the same as in the 1890s but was three times greater than shortly after the Civil War. Per capita consumption in the 1960s, however, was less than half the 1890s amount and only about two-thirds the post-Civil War amount. Per capita consumption figures for selected years were: 1859, 262 bd.ft.; 1899, 456; 1907, 509 (all-time high); 1919, 324; 1929, 268; 1949, 225; early 1960s, about 200.

Canada.—Lumbering is one of Canada's major industries.

More than one-third of the country is covered with forests, of which 450,000 sq. mi. with more than 250,000,000,000 bd.ft. of sawtimber are productive and accessible. But the nature of the terrain precludes easy access to much of the forested area.

A wide variety of commercial trees thrive in Canada. The mainly pulpwood species—spruce, balsam fir, jack pine and aspen—are concentrated in a broad belt reaching from Manitoba to Newfoundland. These species, along with white and Norway pine, white cedar and tamarack, also border the Great Lakes. The mild, humid Pacific northwest is the realm of giant conifers, including western hemlock, Sitka and Engelmann spruce, Douglas fir, white pine, larch and cedar. In the drier inland regions and towards the north, ponderosa and lodgepole pines are more numerous.

Newfoundland and the maritime provinces are literally dotted with sawmills, large and small. The manufacture of forest products began there in the 18th century and subsequently became the major local industry. Numerous excellent streams can carry logs from almost every part of the interior.

The province of Quebec is 61% forested, while only 3.6% is used as farmland. The annual production of logs in Quebec is about 12,000,000,000 bd.ft., much of which is pulpwood.

In British Columbia, where half the population depends on forest industries for its livelihood, the annual production of lumber is about 5,000,000,000 bd.ft., which is about four times the lumber production in Quebec. Logs cut from giant trees along the fiord-indented coast are dumped into the tidewater, assembled into rafts or enclosed in booms, and towed to large coastal sawmills, particularly in Vancouver, where ship and rail transportation and a labour supply are available.

In northern Ontario roughly 100,000,000 ac. of forest contain an estimated 40,000,000,000 bd.ft. of softwood sawtimber. However, the hundreds of small sawmills there produce less than 1,000,000,000 bd.ft. of lumber annually. Pulpwood production, once insignificant, has outdistanced lumbering in Ontario and continues to increase in relative economic importance. Huge pulp and paper mills are located in Ontario at Kenora, Fort Frances, Fort William, Port Arthur and Sault Ste. Marie.

The modern trend in Canadian logging is to build sawmills in the forest so as to be near the source of raw material. It is difficult, however, to generalize concerning logging methods in Canada. In many areas logging is fully mechanized. On the other hand, horses are far from obsolete. In portions of eastern Canada conventional methods utilizing horses, sleighs and streams are the rule. In difficult terrain horses prove better adapted and/or cheaper, particularly in small operations.

In mountainous terrain where logging is difficult, many ingenious logging methods have been tried. In high-lead (i.e., high-line) logging, logs are brought down steep slopes, across deep ravines and over swamps at breakneck speed on overhead wire cables. The logs are then hauled to sawmills or are dumped into navigable streams or bays to continue their journey by water. Cable skidding is a preferred method in pulpwood operations where clear-cutting (i.e., total clearance of timber) predominates. The trees are removed in long, narrow corridors extending outward from the landing; the logs are dragged by cable down skidding trails, which join together in herringbone fashion.

The Canadian sawmill industry is characterized by great variations in the size of plants, in techniques and in equipment. There are large, modern plants equipped with hydraulic riderless carriages, double-cut band mills, double edgers, automatic drop-saw trimmers, dry kilns, complete finishing and remanufacturing facilities, and mechanized systems for handling materials, including automatic stackers and unstackers. Year-round operations are made possible by storing debarked logs in a stockpile and transferring them as needed during the winter to a "hot pond" (a log pond heated with steam or electricity to prevent the water from freezing). Hammer hogs and chippers convert sawmill residue into fuel and chips, thus eliminating the refuse burner in which leftovers from the sawmilling process are burned to get rid of them. Most Canadian mills are small, are operated with conventional equipment, including circular and gang saws, and are geared to a six- or seven-month sawing season. In the relatively smaller

timber of eastern Canada the emphasis is on production of wood chips for pulp and paper mills. Some British Columbian mills ship rough lumber to be seasoned and finished at larger centres, or exported to the United States. In general, modern developments in both log and lumber handling stress mobility; e.g., shovel loaders and fork-lift tractors greatly increase the speed and efficiency of woods and yard operations.

More than 90% of Canada's forest land is government-owned. Most of the forested area has been reserved as crown lands controlled by the dominion government. The land is divided into so-called "timber limits"; stumpage rights to the limits are leased to private companies. In times when forests were considered inexhaustible, the policy was to dispose of cutover land to agricultural settlers. Later, forest reserves were established and cutting was regulated with a view to perpetual production.

U.S.S.R.—Forests occupy more than a third of Russia's land area, or roughly 2,600,000,000 acres. It has been estimated that one-third of the world's total reserves of standing timber grow in the coniferous belt, or taiga zone, between the northern tundra and the steppes. The main commercial species are larch, pine and spruce, along with the hardwoods birch and aspen.

Until the 1940s logging practices in the U.S.S.R. were fairly backward. After World War II, beginning with the fourth five-year plan (1946-1950), the high priority given to developing more efficient methods resulted in a transition from seasonal work with horses and human brawn to well-organized mechanized operations with a permanent labour force. This advance was accomplished by applying mechanized techniques observed in the United States and Canada, and by independent research. One of the more significant innovations was the introduction of the concept that the forest should provide the power required for logging. Inferior species of trees and logging waste came to be utilized as fuel either in the form of gas or as electricity generated in wood-consuming power plants. Mobile equipment, such as trucks, tractors and narrow-gauge railroad locomotives, is powered by fuel wood, electricity or petroleum. Electric chain saws are commonly used in felling trees; cable skidders, log loaders and other machinery for handling logs are powered by electricity generated by portable power plants or relayed from nearby power stations.

In Soviet lumbering, logs usually are skidded in tree lengths. Entire trees may be brought to the landings; in this method the work of removing branches, bucking into logs and disposing of slash (debris) is transferred from the stump to the landing, or to larger assembly and processing centres. Various ground, high-lead and overhead cable skidding techniques are employed as alternatives to tractor skidding. A simplified, single-truss cable crane was introduced in 1957. Much emphasis has been given to proper layout of skidways and to organizing the once-haphazard logging operations into logical units with the work performed on an assembly line basis. In some units large increases in productivity were reported; in others satisfactory organization was reached only by trial and error and the goal of eliminating waste generally was not reached. Over half the logs are floated down rivers to manufacturing centres. Archangel, at the mouth of the Dvina river, has long been a sawmilling centre. Sawmills are widely dispersed, with new mills in the virgin timber of the north and east.

Europe.—On the European continent, which was once heavily forested, lumber was abundant and cheap for centuries. As population increased, wood was used freely for heating homes and in such industrial processes as smelting and brick- and glassmaking. As forest lands became depleted they were converted to agriculture. In modern times the forests along the upper Rhine supplied the relatively treeless Netherlands. The enterprising Dutch eventually imported square timbers, resawed them and sold lumber throughout Europe. France, England and later Germany were the principal consumers; eventually the English market was supplied largely from Canada. At one time, great quantities of lumber from Prussia and Poland were assembled in the ports of Danzig, Riga, Memel and St. Petersburg and shipped to western Europe.

Lumbering in Sweden expanded rapidly after 1850, especially in those sectors of the Norrland region convenient to rivers, ports and the superb forests. Swedish timber exports reached a peak in

1903. After World War I the Swedish sawmilling industry developed highly efficient techniques with the triple objective of reducing labour costs through mechanization, converting sawmill waste into usable by-products and improving product quality. By the 1960s lumbering was conducted on a large scale. Logging methods tended to be traditional because of the long, cold winters, the availability of water transportation and the fact that the labour supply was drawn from rural areas. Swedish forest workers alternated between farm and woods employment.

Finland also has excellent coniferous forests and lumbering is also a major industry there. Up to 88% of the output is exported. Lumber and allied forest products are the mainstay of foreign trade for both Finland and Sweden; considerable quantities of pine and spruce (European redwood and European whitewood) and birch plywood are exported annually.

Extensive forests remain in central and eastern Europe, but lumbering is rather poorly developed. Manual and horse-powered practices are typical, mechanized operations appearing only occasionally; however, considerable progress was being made in building access roads and extending lumbering activities to new areas.

Nowhere are forests more valued than in Germany, France, Switzerland and the rest of western Europe. Meticulous forest management and careful milling result in a maximum yield from the limited area of commercial forests. Most countries in Europe, as well as those in the rest of the world, were striving in the 1960's for self-sufficiency in forest products by expanding their logging activities and utilizing secondary species of trees. Europeans were applying technical knowledge to make maximum use of the raw material harvested. For example, lumber was treated with chemicals to protect it against decay, insects and fungi. Preservative treatment also permits the use of fast-growing species of tropical or semitropical trees whose wood is of inferior quality.

Africa.—Africa's equatorial forest consists of a dense 3,000-mile belt reaching from Sierra Leone on the west coast to the great east African lakes. This forest contains large quantities of timber (the exact amount is unknown) and a profusion of species. Some 120,000,000 ha. (1 hectare = 2.471 ac.), or over half the surface, in the Congo region is forested. Trees grow rapidly in Africa because of the warm, humid climate. Commercial logging began early in the 20th century but progress was slow. The demand for tropical woods is limited and the few commercially valuable trees are found in mixed stands; logging and transportation costs are high. The two main exports were mahogany and okoume.

In Nigeria and Ghana, obeche, agba, iroko and sapele woods, among others, are harvested. The forests generally are community-owned, with private companies leasing stumpage rights. Trees are felled by hand ax but crawler tractors, bulldozers and diesel-powered loaders and trucks are used to bring the logs out of the forest. In Nigeria logs are hauled to the river and towed in rafts to sawmills or to peeler plants for making plywood and veneer. Since Ghana has no suitable river, logs are hauled entirely by truck or rail. The mills are equipped with conveyor systems, band saw headrigs and wood-burning steam plants; modern plywood mills have been built.

Outside the central zone, Africa lacks great forest areas, although the semiarid grasslands and plateaus support forest growth of local economic importance. In Sudan the government introduced sawmills and mechanized logging machinery in 1955, but production is on a very small and local scale. Fires periodically burn over portions of the forest, which then revert to grassland or to the growing of inferior species of trees. Parts of Uganda, Kenya, Tanganyika, Angola and Southern Rhodesia also are forested, and considerable logging is done there.

Asia.—China is deficient in timber, although sizable tracts remain untouched in the remote, rugged regions. Access roads have been built into these reserves, particularly in Manchuria and the southeastern and western interior. Massive reforestation and flood control projects are underway. Apparently because of the enormous labour force available, mechanized techniques have not been introduced. The poplar tree occupies an important place in the Chinese economy; it is widely planted and finds many uses.

The teakwood of India and Burma is a prime building material

and is in wide demand. Logging is done by traditional hand methods with buffalo and oxen except on mountainous terrain, where the elephant is used. Some mechanized logging was introduced after the elephant herds became depleted. The innovation of greenfelling permitted easier milling and better seasoning. With this method teak trees are killed by girdling them and letting them stand for three years to dry before logging. Green teakwood logs are too heavy to float; consequently, like hardwoods, they must be transported by animals, rail or truck. Occasionally, heavy logs are buoyed with bamboo floats.

The Indochina countries, particularly Thailand, and Malaysia, and the Philippines, are covered with extensive forests. Malaysia, for example, with an area as large as England, is nearly 75% forested. Only a very small fraction of the timber resources are at present commercially exploited. Teak is the most valuable wood, followed by several species of pine. Most of the timber is of low average quality for which it is difficult to find a market. Nevertheless, it is increasingly being recognized that the forests of these countries are a potentially valuable resource. Various technical assistance and economic development programs are introducing silvicultural practices and more efficient methods of harvesting and utilizing the forests of these far eastern regions. Malaysia in particular has a progressive forest policy and, although overshadowed by rubber and tin, forest products is one of the most important industries in Malaysia.

The Ganges delta region in East Pakistan has 2,000 sq.mi. of forests with many huge trees. The elephant is the preferred source of transport but is being replaced by machines. The main commercial tree is the sundri, which is ideal for shipbuilding and for use as utility poles. The gewa, a softwood species, is valued as a raw material for paper pulp and fibreboard. The lumber industry, however, is relatively undeveloped; one reason is that tigers and crocodiles are a constant hazard to woodsmen.

Turkey launched a program to increase production from its forests and thus reduce lumber imports. North American techniques and equipment were being introduced.

Australia and New Zealand.—The natural forests of Australia are mostly hardwoods of mixed species with many worthless scrub trees. The area of commercial timber is very small but extensive forests have been planted with fast-growing exotic softwoods, and timber from these forests, together with the native eucalypti, which are widely used, and other native trees were expected to reduce Australia's dependence on imported softwoods. To keep pace with the growth of this lumbering industry, logging and milling methods were modernized and in some of the larger sawmills mechanization is comparable to that of North America.

New Zealand's forest industry expanded after World War II and a surplus of forest products was exported. Drawing on European experience, manufacturers treated lumber with preservatives to make maximum use of the lumbering harvest. Moderately dense hardwoods, including beech and tawa, are used in light construction, while native softwoods are used for laminated products.

South and Central America.—Much of South America is covered with forest, only a small fraction of which is accessible commercial timber. In many areas lumbering is conducted on a small scale with relatively crude methods. Large areas are still undeveloped. In Brazil nearly half the land area is forested. The Amazon basin and the rain forests of the Atlantic slopes contain 362,000,000 ha. of tropical hardwoods and 8,800,000 ha. of Paraná pine. The latter is the most important softwood species in South America. In contrast to the commercial hardwoods, Paraná pine grows in dense stands and is relatively easy to harvest. Consequently, the pine industry is well-developed and a large surplus is exported to Argentina, Uruguay, the United Kingdom and South Africa. Logging and milling equipment compare with that of the southern pine areas in the United States, but formidable problems of transportation and seasoning exist.

The Orinoco river basin ranks second to the Amazon area as the most important forest region in South America. Logging in the Orinoco is generally confined to sectors near the river or its tributaries. About 85% of British Guiana is forested, mainly with tropical rain forest trees. A significant lumber industry has de-

veloped there. Paramaribo, the capital city and principal seaport of Surinam, has 16 sawmills, in addition to facilities for making plywood, crates, flooring, furniture and other wood products.

Bolivia, Chile, Colombia and Paraguay also have extensive forests, all of which are largely undeveloped.

In Central America Nicaragua has dense forests but its forest industry, located principally near population centres, is small. Some fine mahogany is harvested in Honduras and in the Dominican Republic. Tropical forests generally are logged only for special timber of the largest sizes; some loggers seek only mahogany. To utilize the hundreds of other species requires road and railroad building, costly mechanical equipment and a market.

LUMBINI, the grove, located near the village of Paderia in southern Nepal, in which, according to Buddhist legend, Gautama Buddha (*q.v.*) was born. There are two references to the name in the Pali scriptures, the first in the narrative poem prefixed to the *Nalaka Sutta* in the *Sutta Nipata*, where it is related how the gods rejoicing in the sky inform the sage Asita that "the Bodhisattva, the incomparable jewel, has been born for weal and happiness in the world of men, in a village of the Sakyas, in the Lumbini country." The other reference is in the *Kathavatthu*, one of the latest works in the canon. The detailed story of the birth as known to Pali Buddhism first occurs in the introduction to the commentary on the *Jataka*. This account says that Queen Mahamaya (of the Sakya people), when her time was come, desired to go to her parents' home at Devadaha. On the way she stopped in the Lumbini grove, her pains came upon her and there the future Buddha was born. The earliest canonical accounts of the birth are not in the Pali canon but in the Sanskrit scriptures of two other schools, the *Mahavastu* (ii, 18) and the *Lalitavistara* (ch. 7). Neither of these works can be put earlier than the 3rd or 4th century A.D., but the discovery of an inscription of Asoka makes it probable that the whole legend was established at least as early as the 3rd century B.C. The inscription, found in 1896, a few miles within the border of Nepal and several miles east of the site of Kapilavasthu (Kapilavastu), the city of Buddha's family, records that "Piyadasi [*i.e.*, Asoka], after he had been consecrated 20 years, came in person and worshipped, because here was born Buddha Sakyamuni. . . ." This makes the date 249 B.C., according to the accepted chronology of Asoka's reign. There is a shrine at the place, now increasingly a site of pilgrimage for modern Buddhists. The shrine contains a bas-relief representing the birth of the Buddha. The legends with their fabulous details are not historical documents, but the archaeological evidence which has accumulated increases the probability that they originated in a historical event.

LUMHOLTZ, CARL SOFUS (1851-1922), Norwegian explorer and naturalist, was born on April 23, 1851, at Faberg in

Gudbrandsdal. After graduating in theology at the University of Oslo, he was sent by the university to Australia (1880-84) and subsequently traveled extensively in Mexico, where he made three expeditions. During World War I he went to India and in 1915-17 visited Borneo. He made extensive collections of zoological material and also of anthropological data and added new information concerning the Tarahumara Indians of Sierra Madre (descendants of the Aztecs) and the language and customs of the Dyaks. He died at Saranac Lake, N.Y., on May 5, 1922. His books include *Blandt Mexicos Indianere* (1902-03; English trans., 1903), *New Trails in Mexico* (1912), and *Through Central Borneo* (1920).

(Ed. He.)

LUMINESCENCE, a process by which some materials emit light when they are relatively cool. Familiar examples of luminescence output are the light emissions from: electronically excited gases in neon lamps and lightning; tiny inorganic crystals used as coatings in luminescent watch dials, television and radar kinescopes, fluorescent lamps, and X-ray fluoroscope screens; and certain organic materials undergoing oxidation in fireflies and glowworms. Because they luminesce at room temperature, such materials emit what is sometimes loosely called cold light.

 5. Efficiency and Luminance

I. INTRODUCTION

The process of luminescence is started by exciting the material, usually with ultraviolet radiation, X rays, electrons, alpha particles, electric fields, or energy liberated during some chemical reactions. Suitable materials convert one or more of these invisible input energies to light.

Few luminescent materials are efficient enough for practical use. The efficient ones are custom-made to convert a particular input energy to light of a particular colour and intensity. The colour is determined by the material, while the intensity depends on the material and the input energy.

Luminescence is an electronic process that functions most efficiently on a localized, subatomic scale. On that scale, input energy is absorbed by an atom that becomes excited internally, without moving and becoming agitated as a whole. The absorbed energy forces the atom's electrons into an unstable arrangement. When the atom reverts to its original condition it ejects the absorbed energy as light.

1. Incandescence and Luminescence.—Incandescence is a process by which materials emit light when they are hot; input of heat agitates the atoms and they collide. Some of the collisions

excite the atoms to emit thermal radiation. Every material emits thermal radiation of colour and intensity that are determined chiefly by its temperature. At room temperature the radiation is chiefly in the invisible far-infrared region of the spectrum. As temperature rises, the radiation shifts toward the visible region, and its intensity increases until the material is obviously incandescent; that is, until there is an appreciable amount of visible light in the thermal radiation. Familiar examples of incandescence occur in burning coal and wood, and in the hot tungsten filaments in conventional lamp bulbs.

The mechanism of incandescence is detrimental to luminescence, because atomic collisions dissipate the input energy that is temporarily localized in the excited atom in luminescence. Therefore, luminescent materials are efficient sources of light when cool, but not when hot.

2. Pigment Action and Luminescence.—Pigments and dyes produce colour effects by selectively reflecting light, without emitting appreciable radiation in excess of their thermal radiation. A red pigment, for example, reflects red light and absorbs the remainder of incident daylight. The energy of the absorbed light is converted to a negligible amount of heat. A suitable luminescent material, however, produces colour effects by absorbing some of the daylight and emitting light of a different colour than that which was absorbed. Some luminescent materials also exhibit pigment action. They can, for example, selectively reflect red light and, by luminescence, convert the energy of absorbed blue and green light to additional emitted red light. Such materials are used for vivid colour effects in outdoor advertising, where some of the input excitation energy comes from the ultraviolet content of daylight. Certain organic luminescent materials transmit or reflect white light and convert ultraviolet to additional blue or blue-white light. They are used in detergents and coatings to enhance the appearance of white fabrics in sunlight.

The colours of pigments and dyes are subtractive, because they arise from selectively absorbed and reflected incident light. When blue and yellow pigments are mixed and viewed under white light, each pigment selectively absorbs some of the incident light and the residual reflected light appears green.

The colours of the light emitted by luminescing materials are additive, because the materials generate the light. When blue-emitting and yellow-emitting luminescent materials are mixed, as in monochrome television kinescope screens, the resultant blue-plus-yellow light appears white (see COLOUR; LIGHT).

II. EARLY HISTORY

1. The Bolognian Stone of Cascariolo.—According to available records, the first significant inquiry into luminescence began with the synthesis of a new material, not with study of the naturally available fireflies, glowworms, luminous sea bacteria and decaying organic matter, lightning, aurorae, or luminescent minerals. The inquiry was started (c. 1603) by an Italian cobbler-chemist, Vincenzo Cascariolo. He found on Monte Paderno, near Bologna, some unusually dense, silvery white stones. They were pieces of the mineral barite (heavy spar) which is chiefly barium sulfate. In typical alchemical fashion, Cascariolo pulverized the stones and heated the powder in contact with coal. He was seeking to convert the stones to precious metals or gems, or to the fabled philosopher's stone that was believed to be able to transmute base metals to gold. When he cooled the heated powder, it was a dull-coloured porous cake by daylight, but showed a purple-blue glow at night. The weak glow kindled hopes of magic properties, particularly when it was recognized that the material was energized by the "golden light of the sun." (Sol, the sun, was the alchemical symbol for gold.) The material was named *lapis solaris*, or "sun stone," and attempts were made to use it to produce gold. Despite its failure to function as the philosopher's stone, it gained fame for its property of glowing at night after exposure to daylight. News of the material was transmitted to Galileo who gave samples to Giulio Cesare Lagalla of the Collegio Romano in Rome. Lagalla was the first to write of the *lapis solaris* in *De phaenomenis in orbe lunae* (1612).

2. Phosphorus and Phosphora.—Many names were proposed

for Cascariolo's new material, including *lapis lunaris*, *lapis illuminabilis*, *lapis lucifer*, *luna terrestris*, and *spongia solis*. The first monograph on the Bolognian stone, by Fortunio Liceti (1640), bore the Greek title *Litheosphorus*, or "stony phosphorus." Thereafter, the word phosphorus ("light bearer") increased in popularity as a designation for Cascariolo's material and others that glowed in the dark. The term also was applied to the chemical element phosphorus after it was extracted from urine by Hennig Brand (1669). It was natural to call the new element a phosphorus because it glowed in the dark when it was moist. It is not excited by daylight; instead, its luminescence is energized by chemical oxidation that ceases when the oxygen is removed or the phosphorus (*q.v.*) is consumed. The original Bolognian phosphorus, on the other hand, luminesces best without chemical change, and it continues to luminesce indefinitely in a vacuum. Modern usage restricts the term phosphorus to the chemical element, as applied by Johann Sigismund Elsholz (1677), while the term phosphor is used for the many fine-crystal luminescent materials that have been made since the original Bolognian stone.

3. Phosphorescence.—This term was used to describe the persistent emission of early phosphors after they were excited by daylight. The apparent porous structure of the material led to the postulate that phosphorescence involved a simple spongelike absorption of light, followed by gradual release of that light in the dark. This notion was discredited (1652) when Nicolas Zucchi showed that the colour emitted during phosphorescence was the same whether the phosphor was excited by white light or by light of several other colours. The implication is that phosphors generate rather than store light. This correct interpretation was not obvious, however, in an age when some people associated light with the human soul or considered light to be a fifth element in addition to earth, air, fire, and water.

4. Fluorescence and Luminescence.—The news of the Bolognian phosphor spread, and a German Jesuit, Athanasius Kircher, studied that phosphor and other luminous materials. In his book *Ars magna lucis et umbræ* (1646) he called attention to the peculiar appearance of an aqueous extract of a wood called *lignum nephriticum*. This solution had been described (1565) as having an unusually intense blue colour by the Spanish physician Nicolás Monardes who recommended the liquid for treatment of kidney ailments. Kircher and, later, Francesco Maria Grimaldi of Italy, and Robert Boyle and Isaac Newton of England, reported that the tincture appeared blue by "reflected" white light, and yellow by the light that was transmitted through the liquid. All of these investigators referred to the blue light as being reflected; the concept of luminescence eluded them. It was not until 1852, after studies of the mineral fluor spar (see FLUORITE) and solutions of *lignum nephriticum*, quinine sulfate, and chlorophyll, by the French mineralogist René Just Haüy, the English astronomer John Frederick William Herschel, and the Scottish physicist David Brewster, that the blue light of *lignum nephriticum* was identified as a luminescence emission by the English mathematician-physicist George Gabriel Stokes. Stokes used prisms and optical filters that were opaque to each others' light to demonstrate that incident light of one narrow spectral region (such as blue) was absorbed in certain clear solids and solutions, and instantaneously produced emitted light in another spectral region (such as yellow) that was not present in the incident light.

For this luminescence, which apparently ceased when the incident light was shut off, Stokes proposed "to coin a term and call it fluorescence, from fluor-spar, as the analogous term opalescence is derived from the name of a mineral." The term fluorescence was thenceforth loosely applied to short-lived luminescence; also, to light emission during excitation, irrespective of duration after the excitation was stopped. These indiscriminate usages made the term fluorescence ambiguous. Phosphorescence should be used for persistent luminescence in general. Fluorescence should be used only for certain limiting cases of short-duration phosphorescence, as from an isolated, nonmetastable, excited atom. A typical persistence of fluorescence is 10 millimicroseconds (10^{-8} sec.) for emission of visible light. The general term luminescence, of Latin origin, including both fluorescence and phosphorescence, was first

BY COURTESY OF (1-3, 5, 6, 7) W. WOOD, (4, 6, 7) ULTRA-VIOLET PRODUCTS, INC.

1. Photoluminescence in a glass tank containing water. Very dilute solutions of the luminescent dyes fluorescein and rhodamine are dropped into the tank, forming graceful vortex rings and whorls as they descend. 1(a) shows the glass dropper above the tank, a second dropper at the left having been removed before a flashbulb was set off directly above the tank. Light from the flashbulb excited the luminescent dyes. 2. Red photoluminescence of a chemical substance in the Harderian gland of a rat under "black light" (ultraviolet radiation). At left is a normal rat with Harderian gland exposed by displacement of the eyeball. Rat at right received a diet deficient in pantothenic acid. In this rat the porphyrins excreted by the Harderian gland have migrated to the nose through the naso-lachrymal duct. These studies were made by H. J. Fidge of the University of Maryland as part of a search for carcinogenic agents. 3. Photoluminescence, under ultraviolet

radiation, of a bottle of milk surmounted by a smaller bottle of evaporated milk. On the right is a circular disk of butter and on the left one of margarine. The four ovals are hen's eggs which luminesce with a scarlet colour due to the presence of a luminescent material with which they became coated during their passage through the oviduct. 4. A specimen of the mineral scheelite, from Tulare county, Calif., photographed (a) in daylight and (b) under ultraviolet radiation in the dark. 5. Specimens of photoluminescent materials. The blue-emitting crystals on the left are fluor spar from which the name fluorescence was derived. 6. A specimen of the mineral willemite, with a centre strip of calcite under ultraviolet radiation. The non-luminescent portions are chiefly franklinite. Specimen from Franklin, N.J. 7. Another specimen of scheelite from Lucin, Utah, photographed under ultraviolet radiation in the dark.

EXCITATION OF LUMINESCENT MATERIALS

Top: Luminescent minerals and synthetic microcrystalline phosphors under (left) white light and (right) ultraviolet radiation in a dark room. Most useful phosphors simply reflect white light, but absorb ultraviolet rays and generate light with a colour that is determined by the composition of the phosphor. Phosphor crystals in the centre row of vials are zinc-cadmium sulfides with 0.01% silver activator. As the proportion of cadmium is changed from zero to 100%, the luminescent colour changes from blue to red. The phosphors in the trays below are zinc-beryllium silicates with manganese activator. As the proportions of beryllium and manganese are increased, the luminescent colour changes from green to red. Duration of phosphorescence (afterglow) also varies with composition

Centre: Patches of synthetic microcrystalline phosphors on a plate in an evacuated cathode-ray tube under (left) white light and (right) under a beam of 12,000 volt electrons from an electron gun. The electron beam was deflected from patch to patch on the outer circle by manually rotating a bar magnet near the neck of the tube. When the magnet was removed, the beam struck the centre patch

Bottom: Left, separate pigments or dyes that selectively reflect blue and yellow light from incident white light provide a mixture that reflects green light. Right, separate phosphors that emit blue and yellow light under ultraviolet irradiation, in a dark room, provide a mixture that emits white light

introduced by the German physicist Eilhard Wiedemann (1888) for "all those phenomena of light which are not caused solely by a rise in temperature."

Originally, luminescence was associated with the production of visible light. When it became known that luminescence can also produce such invisible radiation as ultraviolet and infrared, the term was correspondingly broadened. Luminescence is used here in the broad sense, recognizing that there are other detectors of radiation than the human eye.

III. LUMINESCENCE EXCITATION

From Cascariolo's time on, many materials were subjected to different treatments and exposures to find new means for making them luminesce. Iacopo Bartolomeo Beccari, professor of physics, medicine, and chemistry at Bologna, reported (1744, 1747) that glowworms, certain marine life, rotten wood, and the flesh of some birds and mammals emit light spontaneously during putrefaction and chemical change, whereas the phosphors require excitation by grinding, heat, light, or exposure to air. Beccari gave a scrambled catalogue of luminescence classified according to the means of excitation.

In modern terminology, a distinctive prefix is used to indicate the means of excitation; for example, bioluminescence (as in glowworms), chemiluminescence (as in rotting wood), triboluminescence (as in grinding a phosphor), and photoluminescence (as in exciting a phosphor with light).

1. Bioluminescence and Chemiluminescence.—The light from glowworms and fireflies is referred to in the Chinese *Shih Ching*, or "Book of Odes," in the period 1200–1000 B.C. Aristotle (384–322 B.C.) wrote of light from decaying fish, and fostered the concept of cold light by mentioning in his *De coloribus*: "some things though they are not in their nature fire nor any species of fire, yet seem to produce light." Francis Bacon described his experiments on decaying wood that luminesced (posthumous publication in 1627). Alexander Humboldt showed (1799) that rotting wood ceased luminescing when placed in nitrogen or carbon dioxide, and resumed luminescing in oxygen or air. Humboldt also showed that a live jellyfish could be electrically stimulated to bioluminesce.

All these luminescences of naturally occurring organic matter are essentially chemiluminescence, wherein the excitation energy is supplied by excited molecules, molecular fragments, or electron transfers that occur during chemical reactions. These reactions usually involve oxidation, as does the chemiluminescence of the element phosphorus. Bioluminescence is chemiluminescence in living things.

In the plant kingdom, bioluminescent bacteria and fungi emit light continuously, whereas the more complex organisms of the animal kingdom can control their emission of light. Some animals regulate the emission of light by controlling the influx of air that provides the oxygen for reaction with organic fluids that are synthesized in the animal. Glowworms and fireflies thus glow periodically to attract mates during courtship. According to Thomas Bartholin, Carolus Vintimillia (c. 1647) first called attention to the significance of this intense, periodic, green-yellow glow. The rare "railroad worm" of South America emits red light from a spot on its head, and green-yellow light from rows of spots along each side. It is a beetle larva, about two inches long. Its glow can be stimulated mechanically and electrically, as can the bioluminescences of other animals. The greenish-yellow sidelights glow when the larva is shaken, and the red headlight glows when air is blown on it. (See also BIOLUMINESCENCE; FIREFLY; GLOW-WORM.)

2. Triboluminescence.—The emission of light upon the scratching or breaking of cakes or crystals of sugar was mentioned by Bacon in *Advancement of Learning* (1605). It was called triboluminescence although the name is inappropriate because the prefix *tribo* means "to rub" (Greek). Numerous organic and inorganic materials luminesce when scratched, broken, or ground, and the phenomenon is allied to the blue glow observable when some adhesive tapes are unrolled in the dark. The surfaces that are mechanically separated have unequal electric charges and discharge

through the intervening space. The blue glow seen on unrolling adhesive tape is that of atmospheric nitrogen excited by the discharge, and the glows seen on breaking crystalline materials are from the air and from the material excited by the discharge. They are mechanically produced electroluminescences.

3. Thermoluminescence.—This name, another misnomer, was used to denote light emission from crystals on being warmed. Boyle observed such emission from a diamond (1663), and Elsholz saw similar effects in fluorspar (c. 1676). The effects caused confusion, because they seemed to indicate that heat alone could excite a luminescent material. More than two centuries of experimenting elapsed before it was realized that heat simply accelerated emission of light by materials already excited by other means, such as exposure to ultraviolet radiation or electric discharges. This phenomenon is heat-stimulated (thermostimulated) phosphorescence.

4. Photoluminescence.—Monardes saw a strange light emitted from his tincture of lignum nephriticum (1565) without appreciating its significance. The realization that a material could be photoexcited to produce light was delayed until Cascariolo's discovery (1603). Nearly two centuries then went by before such invisible radiation as ultraviolet and infrared became known. Johann Wolfgang von Goethe reported in *Farbenlehre* (1810) that he and Thomas Johann Seebeck in 1792 observed light emission when a Bolognian phosphor was held in the invisible region just beyond the violet rays from a prism. (Later, phosphors gave the first indications of other important invisible radiations.)

Positive identification of ultraviolet rays was made by Johann Wilhelm Ritter (1801). He tested phosphors under ultraviolet, and under the infrared rays that were discovered at about the same time. Ultraviolet excited phosphors very well, but he and Seebeck found that infrared decreased the intensity of emission during phosphorescence. This quenching of phosphorescence was later found to be specific for certain phosphors and certain wavelengths. Photoquenching converts stored excitation energy into heat instead of light. With some other phosphors, and selected wavelengths of infrared, the intensity of phosphorescence emission is increased. This stimulation by photons (photostimulation) is similar to that produced by heat, but the mechanisms differ.

5. Stokes' Law.—In about 1852 Stokes showed that the wavelength of the emitted light was always equal to or longer than that of the exciting light. This relationship is called Stokes' law. It was disputed for several decades, but it is valid for most photoluminescences, except those rare instances when thermal energy contributes slightly to the input excitation energy, and when very intense photon irradiation, such as with laser beams, produces multiple excitation or frequency multiplication (see LASER; MASER).

6. Electroluminescence.—In 1672, Otto von Guericke, mayor of Magdeburg, Ger., saw light from a ball of sulfur that he rubbed in the dark, and he likened the effect to that seen when sugar is ground. He also noticed roaring and crackling sounds from the ball that he had electrified by rubbing. He thus took a major step toward Benjamin Franklin's identification (1752) of the electric discharge as responsible for energizing the luminescence displayed during lightning. Lightning and Guericke's luminescence both arise from electric discharges through a gas, and both are electroluminescence. Electroluminescence is luminescence in any material that is excited by electrons. It is common to use electric fields to accelerate electrons and make them energetic enough to excite luminescent materials. The electric field may be constant or alternating, and the electrons may originate outside or inside the material.

The first reported electroluminescence in an evacuated vessel is attributed to Jean Picard, a French astronomer and priest, who (1675) noticed a glow above the mercury in his barometer as he carried it into a dark room. The glow ceased when the mercury was still, and appeared when the mercury was moving downward, but not upward, in the glass tube. Johann Bernoulli, a Swiss mathematician, reported (1700) that an evacuated clean glass phial containing some clean mercury glowed while it was shaken. The effect is due to electric discharges from the glass when the mercury is moved rapidly away and leaves an excess of electrons on the

newly exposed glass surface. The charging effect was demonstrated by a Berlin physician, Christian Friedrich Ludolff (1745), by movements of silk threads he suspended near the moving surface of the mercury next to the glass wall of the tube. Francis Hauksbee, a self-educated English scientist, obtained light (1705-11) by electric discharges from many materials (including glass, oyster shells, wool, and flint) that were electrified by rubbing or fracturing in a partial vacuum.

Further studies led the English physicist, John Canton (1768), to observe that phosphors could be excited by electric sparks. As the means for achieving higher voltages and stronger electric discharges in rarefied gases were improved, there was increasing interest in practical application of electroluminescence. One of the earliest demonstrations of an electric discharge lamp was by J. P. Gassiot at a meeting of the Royal Society, London (1860). Gassiot's lamp utilized a high-voltage discharge through carbon dioxide at low pressure to give "a brilliant white light." Gaseous-discharge lamps were further developed by Daniel McFarlan Moore of the U.S., and by Georges Claude of France, in the period 1890-1900. The modern fluorescent lamp appeared in the latter part of the 1930s. It combines electroluminescence and photoluminescence in that accelerated electrons excite mercury gas atoms that emit ultraviolet radiation which in turn excites a phosphor coating that emits light (see LIGHTING).

7. Cathodoluminescence.—This term is a partial misnomer, because in this process accelerated electrons are used to excite a luminescent material, and so cathodoluminescence is a subclass of electroluminescence.

In 1858, Julius Plücker discovered that invisible rays were emitted from the cathode of an evacuated electric-discharge vessel, and that these rays could be deflected by a magnet, as evidenced by the movement of a spot of light emitted from the glass wall of the vessel where the rays impinged. Further experiments, especially by A. E. Becquerel, Gassiot, J. W. Hittorf, E. Goldstein, Wiedemann, P. E. Lecoq de Boisbaudran, William Crookes, and P. E. A. Lenard, established that the rays could produce bright luminescence emission from many phosphors, including some naturally occurring minerals. Goldstein discovered (1876) that the rays could be electrostatically deflected, and named them cathode rays (German, *Kathodenstrahlen*). Not until 1897 were cathode rays shown to be electrically charged particles by J. J. Thomson, who called them corpuscles. The name electron (*q.v.*), first suggested (1881) by G. Johnstone Stoney for the unit of electric charge, was not generally adopted until after 1900. Investigators bombarded thousands of materials with cathode rays, and obtained striking displays of cathodoluminescence in platinocyanides, uranium salts, diamonds, rubies, and other solid materials.

The first practical device using cathode rays to excite phosphors was the oscilloscope tube invented by Karl Ferdinand Braun (1897). The moving spot of light on the screen of this electron-beam tube made it possible to observe electric and magnetic fluctuations that are too rapid to follow mechanically. Starting in the 1920s the Braun tube was provided with means for modulating the intensity of the electron beam, and with efficient cathodoluminescent phosphors. The cathode-ray tube has since become the kinescope (image-reproducer tube) of television and radar (*qq.v.*). Cathodoluminescent phosphors in the viewing screens of electron microscopes also transform patterns of electron-beam intensity into visible images (see MICROSCOPE: *The Electron Microscope*).

8. Ionoluminescence; Anodoluminescence.—Goldstein discovered rays from anodes, first called canal rays, in 1886. Later identified as positive ions, they also produce luminescence, but are less effective than electrons. Ionoluminescence is an appropriate term to use for luminescence excited by ions, either negative or positive, but the terms anodoluminescence and radioluminescence have sometimes been used as synonyms.

9. Radioluminescence.—After cathode rays, anode rays, and X rays had been discovered (1858-95), Antoine Henri Becquerel of France wondered whether some penetrating invisible radiations might be emitted along with the light from phosphorescing materials. In 1896, he excited some luminescent materials with daylight and then placed them on a photographic plate wrapped in

black paper. When the plate was developed, he found that one of the materials, a uranyl potassium sulfate, had darkened the plate. When he repeated the experiment, without previous exposure of the material to sunlight, he got the same result.

His experiments led to the discovery of radioactivity (*q.v.*); that is, penetrating rays spontaneously emitted from atomic nuclei in uranium, radium, thorium, and other radioactive substances. These rays were found to excite phosphors and the phenomenon was called radioluminescence. The term is ambiguous because the rays include electrons (beta rays), ions (alpha particles), and photons (gamma rays). The so-called radioluminescence was put to use by mixing a phosphor and radioactive material in a paint vehicle to make self-luminous dial markings for watches and other instruments. The scintillations produced by alpha particles bombarding phosphor crystals may be seen in the dark by looking at radioluminescent dial markings through a strong magnifying glass. The separate flashes of light show that the excitation is by particles (see NUCLEAR INSTRUMENTS: *Scintillation Counters*).

The aurorae are radioluminescence on a large scale. Here, the radioactive source is the sun, which ejects such particles as electrons and protons during violent fluctuations of its nuclear reactions. As these particles approach they are deflected by the earth's magnetic field (which is strongest near the poles) and some of them are concentrated in high-lying belts surrounding the earth. Interactions of particles with each other and the upper atmosphere produce the spectacular luminescent displays of the aurora polaris (*q.v.*).

10. Roentgenoluminescence.—This luminescence, excited by X rays, was discovered (1895) in Würzburg, Ger., by Wilhelm Conrad Röntgen, a physicist. He wrapped a cathode-ray tube with opaque black paper and noticed that some nearby barium platinocyanide crystals emitted light when he operated the tube. He then found that invisible rays came from the glass wall of the tube where it was struck by the accelerated electrons. These newfound radiations, called roentgen rays or X rays, were not deflected by electric or magnetic fields, and were much more penetrating than any previously known. They were later identified as being radiation that is the same as light, but of much shorter wavelength.

Many phosphors are roentgenoluminescent; some are used to make X-ray fluoroscope screens and intensifier screens for displaying the intensity patterns of X rays that have traversed optically opaque bodies. X rays are produced by fluorescence involving the innermost electrons of atoms; thus roentgenoluminescence is the second in a two-stage luminescence (see RADIOLOGY).

IV. LUMINESCENT MATERIALS AND PHOSPHOR CHEMISTRY

The Bolognian phosphor, a barium sulfide, was used to make pictures that glowed dimly in the dark, and in moist air it decomposed and evolved malodorous hydrogen sulfide. Despite these shortcomings, its recipe was so highly prized that it was kept secret for nearly a century. The first calcium sulfide phosphor was made (1700) by Friedrich Hoffmann, a court physician in Prussia. He used Cascariolo's technique, heating gypsum (CaSO_4) with coal to make a brighter phosphor. A better technique for making a calcium sulfide phosphor was devised (1768) by John Canton, who heated ground oyster shells with sulfur. Canton's phosphor glowed brighter than the Bolognian phosphor, but both were difficult to reproduce, and both decomposed obnoxiously in humid air. The first stable sulfide phosphor, a zinc sulfide, was prepared (1866) by the French mineralogist, Theodor Sidot, who heated zinc oxide in a stream of hydrogen sulfide.

1. Sulfide-Type Phosphors; Activators; Fluxes.—The difficulty of reproducing phosphors led to the suspicion that impurities might be important constituents. In 1870 there appeared the first commercial phosphor, called Balmain's paint, and in 1879 a German patent on "Leuchtfarben" was issued. Balmain's paint was a calcium sulfide in which was incorporated about 0.01% of a compound of bismuth. In 1886 the French chemist A. V. L. Verneuil showed that a pure calcium sulfide was nonluminescent, but after heating with a trace of a compound of bismuth it gave the violet emission of Balmain's paint. Verneuil thus established the

need for a small amount of activator (e.g., bismuth) in the host crystal (e.g., calcium sulfide). In retrospect, Cascariolo's heavy spar (BaSO_4) and Canton's oyster shells (CaCO_3) apparently contained about the right proportion of bismuth to provide the activator in their phosphors. Sidot's green-emitting zinc sulfide phosphor had a few thousandths of one percent of copper impurity that functioned as the activator.

The best sulfide phosphors were made with about 2% of certain salts in the mixture during heating. Sodium chloride was particularly effective as an additive in making zinc sulfide: copper phosphors, as were several other alkali halides. Almost none of the alkali halide was incorporated in the final phosphor. The beneficial action of these salts led to their being called fluxes, as in welding where certain salts facilitate high-temperature bonding of metals (see FLUX).

2. Oxide-Type Phosphors; Poisons.—After the discovery of activators, the search for new phosphors continued with more attention given to minor ingredients. Among the minerals, bright red emission was obtained from excited specimens of ruby (aluminum oxide with chromium activator), green from willemite (zinc silicate with manganese activator), and blue from scheelite (calcium tungstate, which requires no activator impurity). These materials were then made synthetically with higher efficiencies of luminescence than those of the best naturally occurring specimens.

The higher efficiencies were achieved by eliminating unessential ingredients, and intimate mixing, combining, and crystallizing at optimum temperature and time (usually about $1,000^\circ\text{C}$ for an hour). Great care had to be taken to avoid inclusion of such undesirable impurities as iron and nickel. The efficiency-reducing impurities became known as poisons or killers, and some phosphors were found to be hypersensitive to certain poisons, but relatively insensitive to others. Fluxes, which were essential in making efficient, sulfide-type phosphors, were found to be unessential, and even poisonous, in making oxide-type phosphors.

3. Centres; Intensifier Activators; Originative Activators; Coactivators.—Attempts to explain the roles of activators led to the concept of distinct atoms (or groups of atoms), that Lenard (1890) called centres, in which luminescence takes place. The host crystal was viewed as a medium in which separated activator atoms were suspended and, with their neighbouring host-crystal atoms, provided discrete centres which, when excited, emitted light. As a corollary, poisons were viewed as foreign atoms that incapacitate nearby centres. The optimum proportion of activator was found to be about 0.001–1% of the weight of the host crystal, indicating that centres packed too densely poison each other.

In phosphors that require no added activator, such as pure calcium tungstate and zinc silicate, the luminescent centres may be identified with distinct groups of atoms, such as the octahedral tungstate (WO_6) group in CaWO_4 and the tetrahedral silicate (SiO_4) group in Zn_2SiO_4 (see SCHEELITE; WILLEMITE).

When about 0.2% of titania (TiO_2) is incorporated in pure Zn_2SiO_4 , or in some other pure silicates, the violet emission is greatly increased. A titanium atom apparently increases the luminescent capability of nearby SiO_4 centres, presumably by altering the symmetry of the centres. Impurities that increase latent host-crystal luminescence are called intensifier activators.

When about 0.2% of manganese oxide (MnO) is incorporated in pure Zn_2SiO_4 , the violet emission is replaced by a strong green emission. Here, manganese atoms replace some of the zinc atoms to form new, luminescent MnO_4 centres (and the SiO_4 centres become inactive). Impurities that produce luminescence not ascribable to the pure host crystal are called originative activators.

Another type of activator action was traced to fluxes. Pure zinc sulfide (ZnS) crystallized with 0.01% of a copper salt and 2% of NaCl flux produces a phosphor with a strong green emission. It was found that trace amounts of chloride ions (Cl^-) were incorporated in the ZnS host crystal where they facilitated the incorporation of the copper activator ions (Cu^+) and compensated the electrical charge of Cu^+ . Impurities (e.g., Cl^-) that facilitate the formation of luminescent centres associated with another impurity (e.g., Cu^+) are called coactivators.

Identification of centres, activators, and poisons is a formidable challenge in many phosphors because of the minute proportions involved. In a very pure ZnS , for example, as little as 0.0000001% ($10^{-7}\%$) of copper activator gives a readily discernible green emission. In the same phosphor, as little as 0.00001% of iron or nickel poison discernibly decreases efficiency. Organic luminescent materials also exhibit sensitivity to impurities. The green emission long attributed to pure anthracene (*q.v.*) was found to be due to traces of naphthalene. Pure anthracene has a blue emission from its host-crystal centres, which consist of the planar anthracene molecule $\text{C}_6\text{H}_4:(\text{CH})_2:\text{C}_6\text{H}_4$. When a trace of naphthalene is incorporated, the naphthalene molecule $\text{C}_6\text{H}_4:(\text{CH})_2:\text{C}_6\text{H}_4$ functions as an originative activator.

A shorthand designation of phosphors denotes the crystal class and chemical composition of the host crystal, the activator, the proportion of activator (usually in percent by weight of the host crystal), auxiliary impurities, the temperature and time of crystallization, and other essential data. On this basis, some phosphors and their congeners are shown in Table I.

TABLE I.—Typical Oxide-Type and Sulfide-Type Phosphors

Phosphor	Emission	
	Colour	Persistence
rhombohedral- $\text{Zn}_2\text{SiO}_4:\text{Mn}$ (0.3%), $1,300^\circ\text{C}$, 60 min., slow cool	green	short
β - $\text{Zn}_2\text{SiO}_4:\text{Mn}$ (0.3%), $1,600^\circ\text{C}$, 10 min., quench cool	yellow	short
cubic- $\text{ZnS}:\text{Cu}$ (0.003%): Cl , 950°C , 10 min., slow cool	green-blue	long
hexagonal- $\text{ZnS}:\text{Cu}$ (0.003%): Cl , $1,250^\circ\text{C}$, 10 min., slow cool	green	very long

The examples in the table show that the structure of the host crystal can greatly influence luminescence. $\text{Zn}_2\text{SiO}_4:\text{Mn}$, for example, can be changed from the yellow-emitting form to the structurally different green-emitting form without changing its chemical composition. In these phosphors, the luminescent MnO_4 centres are significantly influenced by structural rearrangements of the surrounding host-crystal atoms.

Phosphors are frequently symbolized in still shorter form, such as rbhd.- $\text{Zn}_2\text{SiO}_4:\text{Mn}$, hex.- $\text{ZnS}:\text{Cu}:[\text{Cl}]$, and tetr.- CaWO_4 . Each such short-form designation represents a family of phosphors, whose members differ in luminescence with differences in the unspecified proportions and ionization states of ingredients and the conditions of preparation. Hundreds of thousands of different phosphors have been synthesized and studied, and a few dozen are in practical use.

4. Gases; Liquids; Crystals; Photons.—Studies of luminescence were extended to rarefied matter after the invention of the vacuum pump by Von Guericke (c. 1650). From studies of rarefied gases, it was determined that every kind of atom (*q.v.*), when alone, will luminesce. When the light that such atoms emit is passed through a prism or spectroscopic sharp lines are seen in some parts of the spectrum. Each kind of atom (there are more than 100 different kinds; see ELEMENTS, CHEMICAL) exhibits characteristic locations and intensities of spectral lines. These have been interpreted in terms of quantum theory (see QUANTUM MECHANICS).

According to quantum theory, an isolated atom or ion can exist indefinitely in an unexcited state (called the ground state) or it can be excited and exist for short periods in one or another of various discrete excited states. In other words, a given kind of atom can exist briefly in one of several separate and distinct states of higher energy, but not in intermediate states. Each state has an energy level that corresponds to a different configuration of the electrons in the atom. When the excited atom drops from a higher to a lower energy level, the difference in energy between the two sharply defined levels is radiated as a discrete bit (quantum) of light that is called a photon.

A lone excited atom loses its excess energy by radiation, in the absence of collisions with other atoms. An excited atom in a molecule, however, can dissipate excess energy by converting it to increased agitation of all the atoms that are bound together in the molecule. Spectroscopic analysis of light from luminescing molecules shows that the energy levels of the constituent atoms

BY COURTESY OF RCA LABORATORIES

FIG. 1.—PART OF THE ENERGY-LEVEL DIAGRAM FOR AN ISOLATED (FREE) ATOM OF MERCURY (HG)

are altered and proliferated into many additional closely spaced levels due to vibrations and rotations of the atomic ensemble. A multiatom ensemble generally has lower efficiency of luminescence than an isolated atom because the assemblage can convert excitation energy into atomic motion, which in condensed matter is thermal agitation (heat).

The probability of dissipating input energy as heat is enormously increased on going from an isolated atom to one bound to myriads of others in an elemental liquid or solid. Most elemental liquids and solids, therefore, are nonluminescent. Mercury is an efficient luminescent gas, but is a nonluminescent liquid. There are some nonelemental liquids, however, that have relatively high luminescence efficiencies. In benzene C_6H_6 (which luminesces as a gas, a liquid, and a solid), the hexagonal benzene molecule is the luminescent centre that emits ultraviolet radiation in all three physical states. As in many other organic substances, the strength of bonding between atoms in each molecule is much greater than that between molecules, and the molecules function as distinct centres. Crystals are generally the most advantageous hosts, because their ordered structures provide stable arrangements of atoms around centres, and permit relatively efficient ingress and internal transport of input energy, and emission of photons.

V. LUMINESCENCE PHYSICS

1. Energy and Spectra; Excitation; Energy Levels; Black

Light.—The basic mechanism in luminescence is conceptually simple. Input energy is absorbed by an isolated atom or centre that becomes excited and then emits a photon when it returns to the unexcited state. According to quantum mechanics, the energy E of the photon is related to the frequency and wavelength of the emitted light by

$$E = h\nu (=hc/\lambda) \quad (1)$$

where $h = 4.141 \times 10^{-15}$ electron-volt second (Planck's elementary action constant in eV sec.); ν is the frequency of the light in cycles per second ($= \text{sec}^{-1}$); $c = 2.998 \times 10^{18}$ ang-

stroms per second (velocity of light in a vacuum, in Å sec.⁻¹); λ is the diffraction wavelength of the light, in Å. (Note: 1 electron volt $= 1.6 \times 10^{-12}$ erg $= 3.8 \times 10^{-20}$ calorie, and 1 angstrom $= 10^{-8}$ centimetre $= 10^{-4}$ micron.) The average person can see light that has photon energies ranging from about 1.8 eV (deep red, near 6,900 Å) to 3.1 eV (deep violet, near 4,000 Å).

Excitation of luminescent materials may be accomplished by photons or charged particles (electrons, ions) with energies equal to or greater than the energies of the photons to be emitted. There is no known upper limit to the energies of primary particles capable of exciting luminescence. Very high-energy particles that exceed the velocity of light in materials lose energy and produce a glow called Cerenkov radiation. This effect is not a true luminescence, because the spectral quality depends chiefly on the excess high energy, not on the nature of the material (see CERENKOV RADIATION). The primary-particle energies used for luminescence excitation generally range from about 3.4 eV, for photons in the near ultraviolet, to billions (U.S. usage: 1 billion $= 10^9$) of electron volts, for energetic particles produced in accelerators such as cyclotrons and synchrotrons (see ACCELERATORS, PARTICLE). Under certain conditions, luminescence may be produced by applying quanta of much lower energy, as is described later in connection with solid-state electroluminescence.

Some phosphors, such as blue-emitting hex-ZnS:Ag:[Cl], may be excited by electrons with energies ranging from about 6 eV to more than 10,000,000 eV. This phosphor is used in television kinescopes, where it is excited by beams of electrons wherein each electron has an energy of about 25,000 eV. The colour of the light emitted is nearly independent of the energy of the particle used for excitation. The energies of the photons emitted are determined chiefly by the composition and structure of the luminescent material.

The detailed mechanism in luminescence is complex, because an atom consists of a nucleus and from 1 to more than 100 electrons. These subatomic particles have intricate interactions, and an atom can exist in only certain overall energy states wherein its electrons exist in many different substates. As an example, a few of the energy levels of an isolated atom of mercury (Hg) are shown in fig. 1.

Each energy level corresponds to a particular overall state (or configuration) of the mercury nucleus and its surrounding 80 electrons. The excited-state energy levels above ground state are those in which the two outermost electrons of the mercury atom have been put into abnormal configurations. By bombarding a mercury atom with an electron having somewhat more than 6.7 eV of energy, for example, the two outermost electrons originally in the $6s^2$ singlet configuration may be excited into the $6s6p$ singlet configuration (see SPECTROSCOPY). When the excited atom returns to the ground state, the excess 6.7 eV is radiated as an ultraviolet photon with a wavelength of 1,850 Å. If, however, more than 10.42 eV of energy were to be absorbed, then one of the electrons would be ejected from the atom, producing a positive ion (Hg^+).

BY COURTESY OF RCA LABORATORIES

FIG. 2.—SOME OF THE PRINCIPAL LINES IN THE ARC EMISSION SPECTRUM OF MERCURY (HG). THE LINES ARE DISTINCT AT A PRESSURE OF 10^{-6} CM. (OF HG) BUT GENERALLY BROADEN AND BECOME DIFFUSE BANDS AT 10^{-4} CM. ALSO, THE MEAN RADIATED-POWER DISTRIBUTION SHIFTS TOWARD LONGER WAVE LENGTHS WITH INCREASING PRESSURE

Luminescence transitions in a mercury atom occur in the region between ground state, at zero ev, and ionization threshold, at 10.42 ev. Within that span there are many excited-state levels that may be achieved by excitation from ground state, by multiple-stage excitation from a lower-lying excited state, or by emission transitions from higher-lying levels. Not all interlevel transitions occur, however, and those that do have unequal probabilities. Some of the permitted transitions are shown in fig. 1, with corresponding spectral locations shown in fig. 2.

The 2,537-Å emission is particularly strong when rarefied mercury gas at about 10^{-5} atmosphere pressure is bombarded by about 100-ev electrons. Under these conditions at room temperature, about 60% of the input electron energy is converted to the 2,537-Å radiation used to excite phosphors in fluorescent lamps (the phosphors, in turn, convert the invisible 2,537-Å radiation to visible light). As indicated in fig. 2, the spectral quality of luminescence emission from mercury gas varies with pressure.

At high pressures, the high frequency of collision with other atoms de-excites, or further excites the already excited atoms. When mercury-vapour lamps are operated at about 8 atmospheres pressure, the 3,650-Å emission transition is prominent. Such lamps are used, with suitable filters, to provide invisible near-ultraviolet radiation.

Ultraviolet radiation is commonly called black light. Ultraviolet lamps are used to excite photoluminescence for decorative and theatrical effects. The lamps also are used in prospecting for luminescent minerals; in disclosing otherwise invisible luminescent markings for laundries, flaw detection, and criminological investigations; in detecting diseased tissues in agriculture and surgery; and in disclosing flow and seepage paths of luminescent fluids. Natural teeth luminesce with a pale blue glow under ultraviolet irradiation.

2. Time Aspects; Growth and Decay; Trapping; Stimulation; Quenching.—The first observations of the persistence of luminescence after cessation of excitation were made visually. A century and a half elapsed before it was found that the visual process itself is persistent, and was eventually found to persist for about 0.1 sec. Luminescences that persisted longer than 0.1 sec. were the first to be observed, and were called phosphorescence. When Stokes (1852) identified a luminescence that had an imperceptibly short persistence, he called it fluorescence, and contended it was distinct from phosphorescence. A. E. Becquerel (1854) disputed Stokes, and devised a mechanical-optical device, called a phosphoroscope, to detect phosphorescences as short as 0.0001 sec. Since 1897, cathode-ray oscilloscopes have been used to show duration of phosphorescence down to 10^{-9} sec. At present, fluorescence is recognized as a limiting case of phosphorescence. Fluorescence is spontaneous luminescence as may be exhibited by a simple, isolated, excited atom.

A spontaneous transition, with emission of a photon, is usual for an excited luminescent atom returning to the unexcited state. In an assemblage of excited atoms, individual spontaneous transitions occur independently; thus the usual light output from luminescent materials is incoherent because the photons are not generated in unison.

It is sometimes possible to induce an assemblage of atoms or ions to make mostly stimulated transitions. Here, the return to the unexcited state is stimulated (triggered) by input radiation with the same frequency as that of the luminescence emission. The concept of stimulated transitions was introduced by Albert Einstein (1917) who calculated the probability of an induced radiative transition from the excited state. Stimulated transitions are used in lasers and masers to produce intense beams of coherent monochromatic light. The beams are generated by luminescent materials in an optical cavity in which standing waves are produced by first raising more than half of the line-emitting atoms (ions) to the excited state, and then stimulating their de-excitation with input radiation that has the same wavelength as the luminescent photons.

The duration of fluorescence is a fundamental quantity related to the energy, or frequency, of the spontaneously emitted photon. For an allowed radiative transition of an excited, isolated atom,

the natural fluorescence lifetime in the excited state is

$$\tau_f = \frac{1}{2}\pi\Delta\nu \text{ sec.} \quad (2)$$

where $\Delta\nu$ is the frequency width of the emission line, measured at half the peak intensity. Equation (2) is derivable from equations (1) and (5). Classically, for emitted photons of frequency ν_0 ,

$$\Delta\nu = 3.93 \times 10^{-23}\nu_0^2 \text{ sec.}^{-1} \quad (3)$$

from which the energy width of the emission line is

$$\Delta E = h(\Delta\nu) = 1.66 \times 10^{-27}\nu_0^2 \text{ ev} \quad (4)$$

and, according to the uncertainty principle for complementary energy and time, the minimum value of τ_f is

$$\tau_f \approx h/2\pi\Delta E \text{ sec.} \quad (5)$$

Equations (1), (4), and (5) indicate for emission of optical photons with a wavelength of 6000 Å that $\nu_0 = 5 \times 10^{14} \text{ sec.}^{-1}$, $\Delta E \approx 4 \times 10^{-8} \text{ ev}$, and fluorescence duration $\tau_f \approx 1.6 \times 10^{-8} \text{ sec}$. For emission of X-ray photons, with wavelengths less than 1 Å, line widths as large as 3 ev have been observed, and the corresponding fluorescence duration from equation (5) is $\tau_f \approx 2 \times 10^{-16} \text{ sec}$. (A more precise expression for $\Delta\nu$, which does not greatly change the indicated value of τ_f for optical photons, is given by quantum theory as

$$\Delta\nu = 32\pi^2\nu_0^3|\mu|^2/3hc^3 \text{ sec.}^{-1}$$

where μ is the quantum-mechanical matrix element of the dipole moment. For photons of wavelength 6000 Å, μ would have a value of about 6×10^{-18} electrostatic units [esu] to correspond to the classical expression given in equation [3].)

If there be a number N^* of excited, isolated atoms (centres) at time t , then the intensity of spontaneous luminescence emission from the N^* atoms is

$$L = -dN^*/dt = aN^* \quad (6)$$

meaning that the number of photons emitted at time t is equal to a rate constant times the number of excited atoms existing at time t . Integration of equation (6) gives

$$-\log_e L = -\log_e N^* = at + [\text{constant}] \quad (7)$$

and, when $t = 0$ (instant of cessation of excitation) and $N^* = N_0^*$, the [constant] = $-\log_e N_0^*$. The rate constant a is equal to the reciprocal of the lifetime τ of the excited state,

$$a = \tau^{-1} \quad (8)$$

and τ is the time taken by the assemblage of excited atoms to decrease (decay) in emission intensity to $L_0 e^{-1}$ ($= 0.368L_0$) when L_0 is the intensity of emission at $t = 0$. On this basis, equation (7) becomes

$$L = L_0 e^{-at} = L_0 e^{-t/\tau} \quad (9)$$

Equation (9) represents a simple exponential decay of emission intensity with time, and is identical in form with the familiar equation for the decay of radioactivity.

When a luminescent material exhibits a simple exponential decay of emission intensity after excitation, it exhibits also an exponential growth of emission intensity during excitation. During excitation

$$L = dN^*/dt = I(N_0 - N^*) - aN^* \quad (10)$$

where I is the intensity of excitation applied to the initial N_0 unexcited centres, and continued. Rearrangement, integration, solving for the integration constant at $t = 0$, and substitution lead from equation (10) to

$$L = aIN_0(1 - e^{-(a+I)t})/(a+I) \quad (11)$$

At low excitation intensities, the time required for the emission intensity to increase and become substantially constant is approximately τ ($= a^{-1}$), and the emission intensity L is determined chiefly by the excitation intensity I . At excitation intensities higher than the value of I required to excite all of the N_0 centres in a time τ , the time required for the emission intensity to become

constant is shorter than τ and is inversely proportional to I . In this saturated condition, the emission intensity is determined chiefly by $N_0 a$ ($\equiv N_0/\tau$).

If the excited atoms (centres) come in contact with other atoms during their excited-state lifetimes τ , some of the N^* atoms can become de-excited by radiationless transitions. Their potential photoemission energy is then converted to heat. Under such conditions, which obtain in dense gases, liquids, and solids, the effective excited-state lifetime τ_e includes the temperature-insensitive radiative decay rate a , and a temperature-sensitive nonradiative decay rate a' , such that

$$\tau_e = (a + a')^{-1} = (a + \nu_e e^{-\Delta E^*/kT})^{-1} \quad (12)$$

where ν_e is the number of collisions per second suffered by the excited centres, ΔE^* is the activation energy that must be imparted to the excited centre to cause it to transfer its excitation energy into heat energy, $k = 8.62 \times 10^{-5}$ eV degree $^{-1}$ (Boltzmann's constant), and T is the temperature of the luminescent material, in degrees Kelvin ($^{\circ}$ K). Substituting τ_e for τ in equation (9) gives

$$L = L_0 e^{-(a + \nu_e e^{-\Delta E^*/kT})t} \quad (13)$$

which is representative of the actual exponential decays of many dense luminescent materials.

In a crystal, the collision frequency ν_e is approximately the same as the highest vibration frequency of the atoms. A typical value of ν_e is about 10^{12} sec. $^{-1}$, and so an excited centre with lifetime as short as 10^{-8} sec. has about 10,000 thermal-agitation collisions during this period. Under these conditions the activation energy ΔE^* should exceed about $30kT$ to yield a high probability that the excited centre will emit a luminescence photon. At room temperature (nearly 300° K) the value of kT is about 0.025 eV, and $30kT$ is about 0.75 eV. Lower values of ΔE^* require lower operating temperatures for efficient luminescence.

It is possible to decrease observed decay time of luminescence to periods shorter than τ , or even τ_e ($\approx 10^{-8}$ sec.), by either decreasing ΔE^* or by increasing T . Both expedients decrease the efficiency of luminescence. The value of ΔE^* in a phosphor may be decreased by increasing the proportion of activator beyond its optimum, or by incorporating poison-type impurities.

Decay times longer than 10^{-8} sec. can be obtained by using semiallowed radiative transitions in isolated atoms, or by using suitable neighbouring atoms to alter the excited-state lifetimes of certain atoms or centres in a liquid or solid. Examples of the influence of the host crystal on the lifetime of the excited state of manganese centres in several phosphors are given in Table II. All of the listed phosphors have exponential decays of phosphorescence emission.

The data in Table II provide clear evidence of the potency of atomic interactions in altering excited-state lifetimes and energy levels of luminescence centres in solids. Advantage is taken of atomic interactions to make phosphors and other electronically active solids with specific characteristics for practical uses. For this purpose, inorganic solids are usually more versatile than organic solids.

Inorganic solids permit broad use of combinations of atoms without requiring carbon in the combination; provide the most degrees of freedom in using ionic, covalent, and intermediate

FIG. 3.—DIAGRAMMATIC REPRESENTATION OF THE DYNAMICS (GROWTH AND DECAY) AND TERMINOLOGY OF LUMINESCENCE EMISSION

types of interatomic bonding; and provide the greatest range of bonding energies, as shown by the high melting points of many inorganic solids.

Trapping is another prominent mechanism for extending the duration of phosphorescence. In many solids this mechanism proceeds as follows: (1) excitation energy ejects an electron from a luminescent centre in a host crystal; (2) the excited electron is trapped in an imperfection elsewhere in the crystal; (3) additional energy, usually heat or infrared radiation, must then be imparted to release the electron from the trap; and finally (4) the electron returns to the centre to be captured and make a radiative transition to the ground state in the usual manner. By inserting a trapping step between the excitation and emission steps, it is possible to prolong phosphorescence for days and even years. Trapping was responsible for the long afterglow of the Bolognian phosphor, and what was mistakenly called thermoluminescence.

The trapping mechanism in solids has its counterpart in the metastable excited states of isolated atoms in gases. A metastable state, such as the $6s6p$, 3P_0 state of mercury shown in the centre of fig. 1, is one from which the excited atom cannot go directly to a configuration with lower energy. Instead, additional energy must be supplied to excite the atom into a higher energy level, such as the $7s$, 3S_1 level, from which a radiative transition can occur. The additional energy can be supplied by collision with other atoms, or by photons. If collision energy be used, the release of stored energy in metastable states is strongly temperature-dependent and follows a relation of the type

$$N^* = -dN_m^*/dt = N_m^* \nu_e e^{-\Delta E^*/kT} \quad (14)$$

where N^* is the number of atoms elevated from the metastable state to a given excited state from which radiative transitions can be made, N_m^* is the number of atoms in the given metastable state, ν_e is the frequency of collisions (proportional to $T^{1/2}$ in gas), and ΔE^* is the energy difference between the N^* radiative level and the N_m^* metastable level. Under these conditions in the absence of re trapping in the metastable state, equation (14) leads to a phosphorescence emission that has a temperature and time dependence according to

$$L = L_0 e^{-\nu_e t} e^{-\Delta E^*/kT} \quad (15)$$

Equation (15) represents the rate-determining process for the simplest case of transitions between one discrete trapping level and one discrete radiative level. In crystals, however, there are usually many trapping levels with different values of ΔE^* . The contributions of different numbers of traps with different depths require that equation (15) be expanded to a series of terms with different values of L_0 and ΔE^* . For a hypothetical uniform trap distribution, that is, an equal number N_t^* of traps of all

depths

$$L = N_i kT(1 - e^{-v_0 t})/t \quad (16)$$

which reduces to a hyperbolic relationship

$$L = N_i kT/t \quad (17)$$

when $v_0 t$ is much larger than unity. Many sulfide-type phosphors at room temperature have emissions that decrease approximately as the reciprocal of the time after excitation is stopped. The exact relationship cannot be exhibited because then the total light output, called the light sum, would integrate to infinity.

A summary of luminescence growth and decay, with corresponding terminology is given in fig. 3. The slow-decay curve 2 is typical of phosphors, such as hex.-ZnS:Cu:[Cl], that have traps that are about 0.5 ev deep; that is, $\Delta E^* \approx 0.5$ ev. Room temperature suffices to release trapped electrons and give phosphorescence emission that can be seen for many hours by the dark-adapted eye. Integration of the decay curve, and comparison with the volume of excited phosphor, gives light sums as high as 10^{18} photons (traps) per cubic centimetre.

The identity of the traps is obscure in most phosphors, but in cub.-Sr(S:Se):Sm:Eu:[SrSO₄:CaF₂] the samarium (Sm) has been identified as providing the traps, while the europium (Eu) provides the luminescence centres; the ingredients indicated in brackets are fluxes. In this sulfoselenide phosphor, which is distantly related to the Bolognian phosphor: (1) 3 ev of excitation energy (e.g., a photon of blue light) ejects an electron from a Eu²⁺ centre, which becomes Eu³⁺; (2) the excited electron is captured by an Sm³⁺ trap, which becomes Sm²⁺; (3) 1 ev of heat or infrared stimulation energy releases the electron from the Sm²⁺, which reverts to Sm³⁺; (4) the electron is recaptured by an Eu³⁺, which becomes an excited Eu²⁺; and (5) the excited Eu²⁺ centre makes a radiative transition to the ground state, emitting a photon with an energy of 2.2 ev (yellow light). The cub.-Sr(S:Se):Sm:Eu:[flux] phosphor is able to store trapped electrons for many months, even at room temperature, because its trap depth is very large relative to the heat energy (kT) of the solid. This phosphor has been used in devices for viewing scenes at night by reflected infrared radiation from an infrared lamp. Deep-trap phosphors can be used, also, for storage and later read-

out of information.

Some of the spectral and dynamic aspects of the luminescence of a cub.-Sr(S:Se):Sm:Eu:[flux] phosphor are given in fig. 4. The photostimulation curve (c), representing accelerated release of trapped electrons by infrared irradiation, has its counterpart in a thermostimulation curve, wherein the accelerated release is accomplished by heating the excited phosphor. When such a phosphor is excited at a low temperature and later heated, the curve of thermostimulated emission as a function of time of heating is called a glow curve.

Light sums may be obtained by integration of photostimulation curves or thermostimulation curves. The conventional phosphorescence of a trap-type phosphor at room temperature is a thermostimulated phosphorescence.

As shown in fig. 3 and 4, stimulation which leads to luminescence has its opposite in quenching, which converts stored excitation energy to heat. Quenching may be accomplished by having poison-type impurities in a phosphor, and then ejecting electrons so vigorously from traps that the electrons go far afield and encounter the poison sites. Incorporation of a trace of iron in hex.-ZnS:Cu:[Cl], for example, transforms the normal stimulation effect of broad-band infrared radiation into a rapid quenching of phosphorescence emission.

3. Emission Spectra of Phosphors; Cascading; Sensitization.—The sharp lines of emission from isolated atoms, as shown in fig. 2, become broadened when the excited atoms collide with other atoms. In a luminescent gas, broadening increases with temperature and density of the gas. In liquids and solids the alteration of energy levels is so pronounced that most phosphor emission spectra are bands instead of lines at room temperature. Notable exceptions are the intense line emissions of rhhd.-Al₂O₃:Cr³⁺ and cub.-CaF₂:Dy²⁺, used in lasers, and the strongly cathodoluminescent cub.-Y₂O₃:Eu³⁺ and cub.-YVO₄:Eu³⁺. The luminescence emission band of a hex.-ZnS:Ag:[Cl] phosphor is contrasted in fig. 5 with the bands of thermal radiation obtained from matter at several different temperatures. Luminescence emission is photon emission in excess of thermal radiation.

In contrast with thermal radiation, the intensity of luminescence emission generally decreases with increasing temperature, and the spectrum of emission is usually a narrow band of wavelengths whose shape and spectral location are relatively insensitive to changes in temperature. As shown in fig. 6, the emission spectrum of zinc sulfide crystals may be shifted gradually from blue (curve 1) to red (curve 8) by substituting increasing proportions of cadmium for zinc. This is typical of several other phosphor families in which the emission colour can be made to order by suitable choice of ingredients and conditions of preparation.

In kinescopes for black-and-white television, for example, the luminescent screen is a mixture of microcrystals of a blue-emitting

phosphor and a yellow-emitting phosphor. The blue-emitting phosphor is the one shown as curve 1 in fig. 6, while the yellow-emitting phosphor has a composition and emission spectrum between curves 6 and 7 in the same figure. Kinescopes for colour television have a blue-emitting hex.-ZnS:Ag:[Cl] phosphor, a green-emitting hex.-(Zn:Cd)S:Ag:[Cl] phosphor, and a red-emitting hex.-(Zn:Cd)S:Ag:[Cl] (or cub.-YVO₄:Eu³⁺) phosphor, with the red emitter having the higher proportion of cadmium in the sulfide. Inner coatings for white-emitting fluorescent lamps may be made of a blue-emitting monocl.-MgWO₄ phosphor mixed with a yellow-emitting rhbdl.-(Zn:Be)₂SiO₄:Mn phosphor, or of a single white-emitting phosphor, hex.-Ca₅(PO₄)₃Cl:Sb:Mn, wherein the Sb centres emit blue light and the Mn centres emit yellow light.

Another example of a family of luminescent materials is the

sequence of aromatic organic substances: benzene , naph-

thalene , anthracene , naphthacene

 and pentacene 

Each of these ring-chain molecules is excited by photons in bands of wavelengths just below a certain demarcation wavelength, and emits photons in bands of wavelengths just above the given wavelength. The approximate demarcation wavelengths for this family are: benzene 2,700 Å, naphthalene 3,100 Å, anthracene 3,800 Å, naphthacene 4,700 Å, and pentacene above 6,000 Å. Luminescence wavelength increases progressively with increasing length of the molecule, just as the optimum wavelength of a dipole antenna increases with increasing length of the antenna. Such an orderly unidimensional correlation is not observed in inorganic phosphors, whose centres generally involve a relatively small number of atoms bound in a multidimensional complex of host-crystal atoms.

It is possible to use luminescent materials in cascade, such that photons emitted by one material can be used to excite another. In the preceding sequence the emission from benzene could excite naphthalene, whose emission could excite anthracene, and so forth.

Cascade luminescence is used in certain radar kinescopes that have composite luminescent screens made of a coating of a yellow-emitting hex.-(Zn:Cd)S:Cu:[Cl] phosphor covered with a coating of a blue-emitting hex.-ZnS:Ag:[Cl] phosphor. Electrons in the cathode-ray beam excite the blue-emitting phosphor whose photons excite the yellow-emitting phosphor. The final phosphor has traps that provide long persistence of emission to retain the radar image for later observation. Direct excitation of the final phosphor by the cathode rays is unfavourable, because the highly energetic electrons in the beam locally heat the material and

empty the traps too rapidly. Cascade luminescence also may be accomplished in a single phosphor by having two or more kinds of centres, such that the emission band of one centre overlaps the excitation band of another kind of centre.

Another type of cooperative interaction, called sensitization, can occur between different kinds of centres in a given host crystal. As an example, rhbdl.-CaCO₃:Mn emits orange light under excitation by cathode rays, but is not excited by 2,537-Å ultraviolet radiation, whereas the same orange light is emitted by rhbdl.-CaCO₃:Pb:Mn under the 2,537-Å irradiation. A mechanical mixture of the host crystals with the two activators incorporated separately gives no emission under ultraviolet, showing that cascade luminescence is not involved. In the host crystal with both activators, the lead centres introduce a new excitation band into the host crystal and transfer absorbed energy to the manganese centres by an energy-exchange interaction that does not involve photon emission. A similar sensitization occurs in gases. For example, thallium gas alone is not excited by 2,537-Å photons, but when a little mercury gas is added, the mercury atoms are excited by the photons and transfer their excitation energy to the thallium atoms on collision. In this indirect fashion, the thallium atoms are excited and emit their characteristic spectrum.

4. Solid-State Energy-Level Diagrams; Solid-State Electroluminescence.—The numerous emission lines of isolated atoms, as exemplified in fig. 2, contrast sharply with the single emission bands of centres in many crystalline phosphors, as exemplified in fig. 6. Luminescence band emission in solids, therefore, requires description in terms of energy-level diagrams that differ considerably from the discrete-level diagram shown in fig. 1. Several kinds of diagrams have been evolved, and some have been found useful for general qualitative descriptions.

One type of solid-state energy-level diagram, shown in fig. 7, is adapted from the conventional diagram used to describe luminescence of an isolated diatomic molecule. As applied to a centre, the potential energy E_p of the centre is plotted as a function of the average distance \bar{x} between the atoms, where \bar{x}_0 is the average interatomic spacing of the unexcited centre, and \bar{x}^* is the average interatomic spacing of the centre in its lowest excited state. In a tetrahedral MnO₄ centre, for example, \bar{x} would be the average distance between the central Mn atom and an oxygen atom at a corner of the tetrahedron. Higher allowed excited states are not shown.

FIG. 7.—GENERALIZED ENERGY-LEVEL DIAGRAM OF A TYPICAL ACTIVATOR CENTRE AS A FUNCTION OF AVERAGED INTERATOMIC CONFIGURATION FOR THE GROUND STATE AND ONE (LOWEST) EXCITED STATE

At zero° K the ground-state energy level would be nearly at the bottom of the lowest curve, corresponding to minimum amplitude of atomic vibration. At a higher temperature, such as room temperature, 300° K, the centre has considerable vibrational energy and so the ground-state level lies higher, such as at *a*. If now a bit of excitation energy approximating the energy represented by $b - a$ is absorbed by the centre, the centre may be raised in energy into the excited-state level near E_b^{**} . The excited centre has a different electronic configuration than the unexcited centre, and the atoms of the excited centre readjust in about 10⁻¹² sec. to a new equilibrium spacing \bar{x}^* and excited-state level E_b^* . After the readjustment, the atoms may be arranged differently, with disproportionate changes in distances and angles from the central atom. The energy difference $b - c$, corresponding to the atomic readjustment, is given up as heat to the surrounding host crystal. With the centre in the excited-state level *c*, the length of time before there occurs a spontaneous radiative transition from *c* to *d* depends on the nature of the centre and its host-crystal environment, as indicated in Table II. After the centre has emitted the energy $c - d$ as a photon of light, the electronic configuration has changed back to that of the unexcited centre,

In another method of excitation, an alternating electric field is applied to special phosphor microcrystals embedded in a thin insulating layer of glass or organic material between two electrodes. A suitable phosphor for this purpose is hex.-ZnS:Cu:[I], which is made with a very high proportion of copper activator, and with careful incorporation of the iodine coactivator. Intense luminescence emission may be obtained by applying several hundred volts, at several thousand cycles per second, across a 0.01-cm.-thick layer of hex.-ZnS:Cu:[I] microcrystals in castor oil. Such solid-state electroluminescence has afforded sustained luminances higher than 1,000 millilamberts.

An analogous electroluminescence phenomenon occurs in gases on application of high-frequency, alternating electric fields. Rarefied mercury gas, for example, luminesces visibly when subjected to millimetre waves of electromagnetic radiation. At first glance, this seems to violate the law of conservation of energy, because low-energy photons produce high-energy photons. Energy is conserved, however, because many low-energy photons must be absorbed to produce one high-energy photon. The process can start, when the electric field is applied, by accelerating electrons and ions in the gas, such as the charged particles produced by cosmic rays, or by electrification contact of gas atoms with the walls of the container. Some of the accelerated particles will have their directions reversed by collisions with mercury atoms, so that on reversal of the electric field an accelerated-and-reversed particle is further accelerated, and so on until the energy of the particle is enough to excite or ionize a mercury atom.

Solid-state electroluminescence also may be produced by injecting electrons and positive holes (extracting electrons) into a crystal from electrodes connected to a direct-current source. Referring to fig. 8, electrons may be injected into the conduction band E_C^* , and positive holes into the normally filled band E_H . The electrons and positive holes can recombine across the entire width of the forbidden band $E_C^* - E_H$ to produce recombination or they can recombine through a luminescence centre to produce radiation characteristic of the host crystal, with $h\nu = E_C^* - E_H$, radiation characteristic of the centre. Radiations resulting from recombination-transitions, across the forbidden band in centres, have been observed in crystals of elemental germanium and silicon, and in crystals of such compounds as silicon carbide, gallium arsenide, and cadmium sulfide. Another variation of electroluminescence occurs at the surfaces of oxidized electrodes (particularly aluminum electrodes) during electrolysis. This phenomenon, called galvanoluminescence, was observed by F. Braun (1898).

5. Efficiency and Luminance.—Efficiency of luminescence, on both a quantum and energy basis, can approach 100% for resonance excitation and radiation of isolated atoms in a rarefied gas. Under these ideal conditions, each absorbed primary photon excites an atom that then emits a luminescence photon of the same energy as the primary photon. The input and output quanta are nearly identical in number and energy. When the energy of the primary particle is greater than that of the emitted photon, however, the energy efficiency is decreased. In the off-resonance condition, there is less effective coupling between the primary excitant and the system to be excited, and at least part of the energy difference is dissipated as heat. Heat losses are aggravated in condensed luminescent materials, such as liquids and crystals. When phosphors are excited by high-energy particles, as in kineoscopes, X-ray fluoroscope screens, and scintillation-counter crystals, the energy efficiency of the process is usually less than 20%. The remaining 80% or more of the input energy is wasted as heat. Solid-state electroluminescence, and the electroluminescences of gases excited by radio-frequency waves, is also relatively inefficient, with more than 90% of the absorbed energy usually dissipated as heat. In a gas excited by millimetre-wave radiation, much of the small-quantum input energy is converted to atomic motion when the accelerated charged particles collide with atoms. There is a major technical challenge in the problem of attaining high efficiency of luminescence when the energy of the input excitation quanta differs greatly from the energy of the quanta of emitted radiation.

The emission intensities of luminescent materials are limited

chiefly by the excitation intensity and by the numerical density and excited-state lifetime of the radiative centres. Intensities of visible emission greater than 10^7 millilamberts have been obtained from certain phosphors under short pulses of cathode rays. A luminance of 10^7 millilamberts corresponds to the emission of more than 10^{20} photons per square centimetre per second. Under sustained excitation, however, the average luminance of cathodoluminescent materials may not exceed about 10^5 millilamberts without unduly heating the material and decreasing its efficiency and output. For comparison purposes, the luminance of fresh snow in full sunlight is about 10^4 millilamberts, an intensity that is painful to see. The intensities of luminescent materials after excitation are determined by their decay characteristics and light sums under the operating conditions.

It is likely that the intensity of phosphorescence emission first observed by Cascariolo was less than 0.001 millilambert an hour or more after excitation. From that feeble beginning came such commonplaces as television kinescopes with luminances of about 100 millilamberts, fluorescent lamps with luminances exceeding 3,000 millilamberts, and lasers with pulsed outputs that exceed the 10^6 candlepower/in.² of the sun.

The many practical uses of luminescence continue to increase. From the scientific standpoint, luminescence is uniquely useful as an instantaneous detector of invisible energetic particles, and as an ultrasensitive indicator of changes of composition, structure, and atomic interactions in many different materials.

(H. W. Lz.)
LUMPFISH (LUMPSUCKER), the name given to several fishes of the small marine family Cyclopteridae. The common lumpfish (*Cyclopterus lumpus*) has the ventral fins united into a circular concave sucker that enables it to attach itself firmly to rocks or stones. The body is short and thick with a thick, scaleless skin covered with rough tubercles. The first dorsal fin is a mere lump on the back. The lumpfish inhabits the coasts of both sides of the North Atlantic. In the spring the fish approaches the shores to spawn, clearing out a hollow on a stony bottom in which it deposits an immense quantity of pink-coloured ova. The male guards the spawn very assiduously until the young are hatched. A lump-

sucker may weigh as much as 20 lb. The male is only one-half or one-third the size of the female, and during the breeding season becomes bright blue, with red below. The bones are soft and contain little inorganic matter.

The arctic lump sucker (*Cyclopterus maculipinnis*) is from the colder northern waters. Several species of spiny lump suckers (*Eumicrotremus*) occur in both Atlantic and Pacific waters.

LUNACHARSKI, ANATOLI VASILEVICH (1875-1933), Russian author, publicist and politician who, with Gorki, did much to ensure the preservation of works of art during the civil war, was born in Poltava and educated at the Kiev gymnasium and at Zurich university. In 1896 he returned to Russia, where his revolutionary activities led to his deportation to Vologda in 1898. In 1903 Lunacharski joined the Bolshevik group of the Social Democratic party, and in 1904 he started to work on the editorial board of the Bolshevik journal *Vpered* ("Forward"). He disseminated social democratic propaganda and organized lectures for Russian students and political refugees in foreign countries.

During the 1905 revolution Lunacharski was arrested and imprisoned. In 1909 he joined Gorki on Capri, where, together with A. Bogdanov, they started an advanced school for a select élite of Russian factory workers, but Lenin's opposition to this project quickly ended it. Lunacharski was preoccupied with the place of religion in the new social order, and in 1909 he published a book titled *Outlines of a Collective Philosophy*. During World War I he maintained an international pacifist attitude. In March 1917 he joined Lenin and Trotski in Russia and was appointed peoples' commissar for education in the same year. This position helped him to preserve many works of art and historic buildings from wanton destruction. His interest in the theatre encouraged a number of dramatic experiments and innovations. He himself wrote 14 plays, of which several were produced in Moscow and Berlin. Three were translated into English, under the title *Three Plays* (1923). In 1933 Lunacharski was appointed Soviet ambassador to Spain, but he died at Menton, France, on Dec. 27, 1933.

(R. HA.)

LUNACY: see **INSANITY**.

LUNATION, the period of return of the moon (*luna*) to the same position relative to the sun; for example, from full moon to full moon. Its duration is 29.5305884 days (see **MOON**).

LUND, a city and seat of a Lutheran bishop in Malmöhus län (county), Swed., is located 16 km. (10 mi.) N.E. of Malmö on the Stockholm-Malmö railway line. Pop. (1960) 40,331. The city centre is dominated by the 12th-century Romanesque cathedral, which has an imposing crypt and a famous medieval clock. Lund is known as the cultural centre of southern Sweden. The university, with faculties of law, medicine, theology, philosophy, science and economics, was founded in 1668. There is a technical high school. The most important of the city's museums are the Cultural History museum, the Archives of Decorative Art and the Art Exhibition hall. The various educational institutions and hospitals of the city employ a considerable part of the population, but there are also important industries, including food-industry equipment, packaging, printing and textiles.

Lund was founded about 1020 by the Danish king Canute, who is said to have named the place after London. In 1060 it was made a bishopric and in 1103 the seat of an archbishop for all Scandinavia. During the middle ages the city played an important part in Danish affairs. It was reduced in importance after the Reformation and the Swedish conquest in 1658, but after 1850 it developed rapidly.

(Sv. M.)

LUNDA, a Bantu people scattered over wide areas in the southwestern part of the Republic of the Congo, eastern Angola, the northwestern corner of Zambia and the Luapula valley. The various regional groups—the Lunda of Musokantanda, Kazembe, Shinje, Kanongesha, Mwinilunga, Ndembu, Luvala (Luena Balovale), Chokwe (*q.v.*) Luchazi, Songo and Mbunda—are all of Congo origin and broke away from the central Lunda kingdom in the Kapanga district of the southern Congo, which is still ruled by the paramount chief, the Mwata Yamvwa. The main dispersal took place about four centuries ago, when the Luba (*q.v.*) hunter Cibinda obtained supreme power from the Lunda queen Lueji.

Most Lunda expansions occurred as peaceful infiltrations. In the southwestern Congo they have spread to the Kwango river, where they form the political authority among the Yaka and other tribes. The matrilineal Bemba (*q.v.*) of Zambia are also associated with them, but it is difficult to trace a direct link. With related people, including the Chokwe, they were estimated to number 1,500,000 in the mid-1960s.

The Lunda inhabit savanna country intersected by belts of forest along the rivers; the Luapula groups occupy flood plains and alluvial lands. Food gathering and hunting are important among many groups, fishing less so, except among the Luapula. All groups practise shifting hoe cultivation of manioc, millet, peanuts, beans and maize, and keep small stock; some groups, such as the Balovale, keep a few cattle. Local trade is widespread; the Lunda of Kazembe have been famous as traders of ivory and slaves.

Descent systems differ: the southern Lunda, Luvala and Luchazi are matrilineal; the Luapula Lunda are said to be patrilineal, whereas those of Kapanga have a bilateral system, which functions over four generations. Inheritance and succession are matrilineal among the southern Lunda, but among the Lunda of Kapanga inheritance is matrilineal and succession to chiefly office is omnilinear within a descent group of four generations. Marriage is, virilocal and residence usually avunculocal (see **KINSHIP**). Marriage payments are low; widow inheritance and cross-cousin marriage are practised. Lunda villages are small and compact. The central political organization is of extreme complexity among the Lunda of Kapanga; there exist a number of independent chiefdoms which have been or still are subordinate to the Mwata Yamvwa. The supreme being is either a sky or an earth god; ancestor-worship is practised.

BIBLIOGRAPHY.—M. McCulloch, *The Southern Lunda and Related Peoples* (1951); W. V. Brelsford, *The Tribes of Northern Rhodesia* (1956); I. G. Cunnison, *Luapula Peoples of Northern Rhodesia* (1960). (D. P. BL.)

LUNDA, the northeastern district of the Portuguese overseas province of Angola in west central Africa, is bordered north and east by the Democratic Republic of the Congo. Pop. (1960) 247,430. Area 64,432 sq.mi. Its capital is Vila Henrique de Carvalho. Lunda is divided into the *concelhos* (counties) of Saurimo and Chitato and the circumscriptions of Camaxilo, Cassai Sul and Minungo. In all these divisions except Chitato the economy is chiefly agricultural (cereals, oil fruits and oil nuts, rubber, cotton, wax, honey). River fishing is important and game abundant. Chitato (area 16,493 sq.mi.) produces about 1,000,000 carats of diamonds annually. The chief centre of the diamond-mining area is Dundo, just south of the Congolese border. (A. A. G. P.)

LUNDY, BENJAMIN (1789-1839), U.S. philanthropist, prominent in the antislavery conflict, was born at Hardwick, N.J., on Jan. 4, 1789. From 1808 to 1812 he lived at Wheeling, Va. (now W.Va.), an important headquarters of the interstate slave trade. There he first became deeply impressed with the evils of the institution of slavery. In 1815 he organized an antislavery association, known as the Union Humane society. In 1821 he founded at Mount Pleasant, O., an antislavery paper, the *Genius of Universal Emancipation*, which he edited at irregular intervals and in diverse places until his death.

From Sept. 1829 until March 1830 Lundy was assisted in the editorship of the paper by William Lloyd Garrison (*q.v.*). Lundy traveled extensively on behalf of the cause, visiting Haiti twice, in 1825 and 1829, the Wilberforce colony of freedmen and refugee slaves in Canada in 1832 and Texas three times, 1830-31, 1833-34 and 1834-35. These visits were made, in part, to find a suitable place outside of the United States to which emancipated slaves might be sent. He was bitterly denounced for his antislavery agitation, and in Jan. 1827 was assaulted and seriously injured by a slave trader, Austin Woolfolk.

He was closely associated with John Quincy Adams in an effort to prevent the annexation of Texas. In 1836-38 Lundy edited in Philadelphia a new antislavery weekly, the *National Enquirer*, which under the editorship of Lundy's successor, John Greenleaf

Whittier, became the *Pennsylvania Freeman*. The last year of his life Lundy spent in Illinois where he died Aug. 22, 1839.

(R. F. N.)

LUNDY (from the Norse: *Lunde* [a puffin] and "ey" [an island]), at the entrance to the Bristol channel, lies 11 mi. N.N.W. of Hartland point, Devon, Eng. It is $3\frac{1}{2}$ mi. long and averages $\frac{1}{2}$ mi. wide with an area of 1.63 sq.mi. The highest point is 466 ft. Pop. (1963) 40, including lighthouse keepers and islanders who work on the mainland in the winter.

The island is surrounded by cliffs, notably Shutter rock at the southwestern end, and is made of granite, except in the southeast where Devonian slates have weathered to give the one landing cove. This is sheltered by Rat Island where the once common black rat survives. Lundy lends its name to a weather forecasting area that extends to the Scilly Isles and the southeastern tip of Ireland. The puffin and many other sea birds breed on Lundy.

A turbulent history includes its use as a base by pirates and smugglers. Owned by the crown from 1150 it was sold by parliament in 1647 to Lord Saye and Sele. The castle was erected between 1170 and 1200 by Sir William de Marisco whose family held the island periodically from 1150 to 1327. The church was built in 1896 by the Heaven family, owners of Lundy from 1836 to 1918. In the 1960s the owner was A. P. Harman. Lundy is reached by boat from Bideford and Ilfracombe. (C. K.)

LÜNEBURG, a town of Germany which after partition of the nation following World War II became part of the *Land* (state) of Lower Saxony, Federal Republic of Germany. It is situated on the Ilmenau, 57 km. ($35\frac{1}{2}$ mi.) S.E. of Hamburg by road where the undulating heathland changes to the alluvial plain flanking the Elbe. Pop. (1961) 59,574.

Lüneburg is one of the few undamaged towns built in the north German Gothic brickwork style. Features of interest include the town hall (13th–18th centuries), with its council chamber containing the wood carvings of Albert von Soest (1567–84); St. John's church (tower completed 1406); the Sand, a beautiful square of Gothic and Renaissance houses; St. Nicholas' church (1409; tower rebuilt 1895); and the ducal palace (1693–96) overlooking the market place. Municipal buildings include brine baths, a library, museum and theatre.

Lüneburg is on the main line from Hanover to Hamburg; other lines run to Lübeck, Dannenberg, Bremen and Buchholz. There is a port on the Ilmenau and the town has several main roads radiating from it. The saltworks have been operating since the 10th century, luxury goods, textiles, wax, building materials and by-products of salt are produced. There is trading in sugar, cereals, coal, salt and bone meal.

First mentioned as "Luniburg" in A.D. 956, Lüneburg probably obtained municipal rights under Henry the Lion before 1200. It was the residence of the Billungs and, later, of the Welfs until 1371. After the establishment of the ducal residence at Celle, Lüneburg enjoyed a period of great prosperity, being one of the chief members of the Hanseatic league, but the town decayed during the Thirty Years' War. Incorporated into Hanover in 1705, it became part of Prussia in 1866. On May 4, 1945, on the Lüneburger Heide to the southwest, Field Marshal Montgomery received the surrender of the German forces in northwest Germany, Denmark and the Netherlands. (G. J. L.)

LÜNEBURGER HEIDE, a district of Germany, in the *Land* (state) of Lower Saxony, lying between the Aller and the Elbe and intersected by the railways from Harburg to Hanover and Bremen to Stendal. Its main character is that of a broad saddleback, running for 88 km. (55 mi.) in a southeast-northwest direction (mean elevation about 250 ft. and greatest height, Wilseder Berg, 561 ft.). The soil is quartz sand and is chiefly covered with heather and brushwood, whose growth forms are caused by the extensive feeding of sheep (the celebrated Heidschnucken breed). In the north and in the deep valleys there are extensive forests of oak, birch and beech, and in the south of (planted) fir and larch. The heather is mixed with broom, gorse and juniper, the latter often forming small pyramidal cypresslike trees. Though the climate is raw and rich soil rare, the heath is not unfertile. The main products are sheep, potatoes, bilberries, cranberries and honey. The

district is also remarkable for numerous megaliths, popularly called *Hünengräber* ("the graves of giants"), and a picturesque countryside with many beautiful old farmhouses with thatched roofs, built in the typical old style of Lower Saxony in red brickwork and oak beams. Large parts of the heath are under protection of the nature conservancy of the Federal Republic of Germany.

(H.-H. He.)

LÜNEN, a town of Germany which after partition of the nation following World War II became part of the *Land* (state) of North Rhine-Westphalia, Federal Republic of Germany. It lies in the open Lippe country about 11 km. (7 mi.) N.N.E. of Dortmund by road. Pop. (1961) 72,171. The palace (1708) was the last seat of the statesman Freiherr vom Stein, and is now the Dortmund museum. Nearby is Schloss Kappenberg, a former Premonstratensian monastery whose Romanesque church has fine early 16th-century choir stalls. Lünen is the headquarters of the Westphalian Symphony orchestra and has various educational establishments. It is connected with the Ruhr and Münster by railway and the Cologne-Hanover motorway passes close by. Mining is the chief industry; aluminum, copper, iron and electricity are also produced.

LUNETTE, a crescent-shaped or semicircular object. In architecture the term is applied to any semicircular shape or panel which is decorated, and especially to those which occur under semicircular arches or vaults. By extension, the term is used of small vaults intersecting a larger vault at right angles, especially if used for lighting the larger vault, as in the clerestories of St. Paul's cathedral in London and St. Peter's in Rome. Oval or circular openings through any vault are also sometimes known as lunettes.

LUNÉVILLE, a town of eastern France, in Lorraine, the capital of an *arrondissement* in the modern *département* of Meurthe-et-Moselle. It is situated on the Meurthe river above the confluence of the Vezouze, 29 km. (18 mi.) S.S.E. of Nancy by road. Pop. (1962) 21,250. It was a walled town in the middle ages. After suffering in the Thirty Years' War and in the campaigns of Louis XIV, it flourished in the 18th century under the last dukes of Lorraine, and became part of France in 1766. The peace of Lunéville, between France and Austria, was signed there in 1801. Lunéville is a good example of 18th-century town planning, the château and church of St. Jacques being the chief buildings of interest. It is on the railway from Nancy to Strasbourg. Modern industrial development, particularly the manufacture of railway stock and other engineering, cotton spinning and pottery making, has been responsible for its modest growth. (Ar. E. S.)

LUNG, in anatomy, the name of each of the pair of organs of respiration in man and other air-breathing animals, the organs in fishes with the corresponding function being the gills. See RESPIRATORY SYSTEM, ANATOMY OF.

LUNG, DISEASES OF, comprise all those disorders affecting the lungs. Other diseases of the chest are discussed in RESPIRATORY SYSTEM, DISEASES OF and PLEURA, DISEASES OF.

Lung Cancer.—Cells of the membrane lining the air passages in the lung undergo a change which leads to uncontrolled cell growth. The result is a malignant tumour which invades and destroys contiguous structures, blocks the air passages and spreads from its point of origin through the lymph channels and the blood stream to other parts of the body with results invariably fatal unless the growth is removed at an early stage. Bronchogenic cancer may be detected by the conventional chest X-ray examination, but the shadows cast by early symptomless cancers, often resembling harmless conditions, are difficult to identify. Thorough medical examination and sometimes exploratory surgery is necessary.

The remarkable increase in lung cancer during the 20th century has caused great concern throughout the world. It has become the most frequently encountered malignant tumour in men, occurring five to ten times more frequently in men than in women. Multiple causative factors may be involved, but the carcinogenic (cancer-causing) chemicals known to be present in the products of combustion are probably of greatest importance. Foremost among the fumes of combustion which enter the human lung in concentrated form is tobacco smoke, and statistical data are available to indicate

that smokers are peculiarly susceptible to bronchogenic carcinoma. The gaseous wastes from combustion of motor fuels and other atmospheric pollution have been accused of causing the high incidence of lung cancer in large cities. (See also CANCER; TOBACCO: *Tobacco and Disease*.)

Tuberculosis.—Although tuberculosis has diminished as a cause of death in most countries where hygienic conditions are optimal, it has diminished less rapidly than other preventable infectious diseases. In some countries it remains a principal cause of disability and death and is a serious social and economic drain upon human resources. Diagnosis of tuberculosis requires routine chest X-ray examinations of well-appearing persons, especially if a positive reaction to the tuberculin skin test has occurred. Shadows on the X-ray film suggesting tuberculosis require general examination and study of sputum and blood for other indications of active infection. Some cases of inactive tuberculosis or those of uncertain activity must be examined repeatedly for many months or years to detect the earliest evidence of activity.

Treatment of active tuberculosis requires the administration of two or more of the several potent antituberculosis drugs. Isoniazid, streptomycin and PAS (para-aminosalicylic acid) are the most commonly used and most safe and effective drugs in treatment of tuberculosis. Treatment is ordinarily prolonged long after every indication of activity has disappeared, two years of specific drug therapy being frequently recommended. Surgical treatment of tuberculosis is necessary to remove areas of infected lung which cannot be treated successfully with drugs alone. Lung collapse, once a popular procedure in the opinion of many specialists, is necessary only in unusual cases.

The prevention of tuberculosis requires that contagious cases be diagnosed promptly and treated successfully, remaining segregated during the period of communicability. Vaccination with bacilli of low virulence, such as the BCG strains, produces some degree of immunity, and such vaccination is desirable in those countries which lack adequate facilities for treatment and isolation of communicable tuberculosis. It is not generally recommended in countries where high standards of hygiene are maintained. (See also TUBERCULOSIS.)

Pneumonia and Pneumonitis.—Inflammation of the lungs, ordinarily acute and extensive, is called pneumonia. Less severe inflammation with less consolidation (filling of air spaces with exudate) is sometimes called pneumonitis. Many inflammatory agents can produce pneumonia, but bacteria and viruses are of greatest importance. Of the many bacteria which alone or in combination may cause pneumonia, the pneumococcus is best known and most often productive of very acute and dense consolidation of one or more lobes (lobar pneumonia).

Diagnosis frequently can be made by physical examination, but X-ray examination is necessary to follow the course of the disease and to detect complications. Distinction between lung cancer, tuberculosis, fungus infections and slowly resolving pneumonia may be very difficult. Treatment of the bacterial pneumonias with antibacterial drugs (antibiotics and other chemotherapeutic substances) is usually successful, and their use has resulted in a greatly diminished mortality rate, especially in cases of pneumococcus pneumonia. Treatment of the virus-caused pneumonias is less specific, but these infections are less likely to cause death and complications are rare. (See also PNEUMONIA.)

Fungus Infections.—Specific treatment (Amphotericin B) is available for serious cases of fungus infections. Coccidioidomycosis in certain dry areas (especially southwestern U.S.) and histoplasmosis of moist climates frequently cause no recognized symptoms but occasionally cause serious disease, sometimes confused with tuberculosis and cancer of the lung. Blastomycosis, cryptococcosis (torulosis) and actinomycosis are rare and often serious infections. (See also FUNGUS INFECTIONS.)

Emphysema.—Overinflation of the lung, an inability to exhale air from the abnormally dilated terminal air sacs (alveoli), is the essential feature of the usual type of pulmonary emphysema. It is attributed to loss of lung elasticity and to obstructive changes in the finer air passages. The obstruction is either of inflammatory origin or due to spasm of the involuntary muscles which encircle

the smaller bronchi. Very prolonged and recurrent bronchial asthma and excessive tobacco smoking are among the recognized causes of pulmonary emphysema. The symptom of progressive shortness of breath on exertion, associated with an abnormally rounded chest (barrel chest), with or without wheezing respiratory sounds, most frequently prompts the patient to seek diagnosis and treatment. Unfortunately treatment is often ineffective when the condition is advanced, and prevention of further injury is all that the physician can hope to accomplish. (See also EMPHYSEMA.)

Bronchiectasis.—Bronchiectasis is a common disorder characterized by dilatation of the bronchi of one or more of the lung segments. Infection often becomes implanted in these bronchi where secretions stagnate. Symptoms of infection with cough, expectoration and recurrent episodes of lower respiratory tract infection are common. Bleeding from the lung is not uncommon. Medical treatment may yield temporary relief, but removal of the diseased segments is necessary for cure. (See also BRONCHIECTASIS.)

Pulmonary Embolism.—Blood may clot within the veins, especially leg veins, under abnormal conditions (thrombosis). If the clot (thrombus) becomes dislodged and is carried to the lungs it lodges in an artery of the lung and is called an embolus. A large embolus may interrupt blood flow and cause almost instantaneous death; small emboli cause less serious manifestations. Thrombosis and embolism occur most commonly after prolonged illness, certain surgical manipulations, fractures and prolonged immobilization. Obesity, varicose veins, advanced age and heart failure are additional predisposing factors. (See also THROMBOSIS AND EMBOLISM.)

Miscellaneous Disorders.—Prolonged inhalation of harmful dusts, especially silicon dioxide and asbestos, may cause permanent lung injury. Mild or severe temporary injury may result from inhalation of irritating fumes (pulmonary edema). (See also DANGEROUS OCCUPATIONS; PNEUMOCONIOSIS.) Lung trauma in wartime and in such injuries as occur from automobile accidents may cause lung puncture and other impairments of function requiring emergency treatment to prevent early death. Lung abscess is usually attributed to inhalation of contaminated and irritating materials such as vomitus and to bronchial obstruction from cancer, foreign body, etc. Many malignant growths, some generalized infections and such disorders as the collagen diseases, sarcoidosis, allergic conditions and parasitic infestations may involve the lungs as well as other organs. See HEART AND LUNG, SURGERY OF; see also references under "Lung, Diseases of" in the Index.

LUNG-CHING (LUNGCHOU, LUNGCHOW, LUNGTSIN), a town of about 14,000 population in southern Kwangsi Chuang Autonomous Region, China, about 6 mi. from the Vietnam border and about 90 mi. S.W. of Nan-ning. It is a river port for small boat traffic on the Li river, and is a highway centre for transborder traffic. It was opened to foreign trade in 1889, after the Indochina railway reached the border, but the failure in development of transport facilities on the Chinese side prevented the growth of important commerce. During the late 1930s, when China was under Japanese blockade, Lung-ching briefly carried on a tremendous trade. (J. E. Sr.)

LUNGFISH, the name given to the fishes of the order Dipnoi (Dipneusti) possessing both gills and a functional lung. One pair of nostrils opens into the mouth. A partly divided auricle is one of the other structures approaching the condition found in terrestrial vertebrates. Lungfishes have long, pointed pectoral and pelvic fins; the caudal fin is continuous with the dorsal and anal fins.

The family Ceratodontidae comprises one surviving species, *Neoceratodus* (or *Epiceratodus*) *forsteri*, of Queensland, Austr.; this species only occasionally breathes surface air. Its food habits are omnivorous, and it may grow to be 6 ft. long. Fossils of related species have been found in many parts of the world, and are generally considered as belonging to a separate genus, *Ceratodus*.

PAUL POPPER LTD.

AFRICAN LUNGFISH (PROTOPTERUS ANNECTANS)

The Lepidosirenidae, including *Protopterus* of Africa and *Lepisodiren* of South America, which inhabit swamps and marshes, must breathe air at frequent intervals; in the dry season, when the swamps dry up, these fishes curl up and rest at the bottom of a burrow, the entrance to which is closed with a plug of mud, with openings for air. These lungfishes are voracious and eat a variety of aquatic animals, including members of their own species. Fishes of other groups, particularly the African bichir (*Polypterus*), have a primitive lunglike air bladder used for breathing air. See FISH: *Survey of the Bony Fishes*; see also references under "Lungfish" in the Index. (C. Hu.)

LUO (Lwo, JALWO), a Nilotic-speaking people numbering about 757,000 in the 1960s and living in the flat country near Lake Victoria in the Kavirondo region of western Kenya; there are a few in the adjoining area of Tanganyika. The Luo are known as Kavirondo throughout east Africa. The area is divided into about 40 administrative units known as locations, which in most cases correspond to the areas traditionally occupied by a subtribe. Each subtribe is politically autonomous, there being no over-all political authority for the whole people. Most men of a subtribe belong to the same patrilineal, exogamous clan which settled in the territory after immigration from the northwest. Many residents are descendants of neighbouring non-Luo tribes which were conquered and partially absorbed by the invaders.

Luo are settled agriculturalists and keep many cattle. They are wealthy, producing much cotton and other cash crops. Luo are found outside Kavirondo throughout east Africa as labourers and tenant farmers on land owned by Europeans and by other tribes, and as workers in urban centres. They are one of the peoples most affected by modern developments in east Africa. Missionaries have been working in their country for most of the 20th century and most Luo are Christians.

The Luo are the most southerly of the large cluster of Nilotic peoples known as Lwo or Lwoo. These originated in the southern Sudan and migrated southward into Uganda and Kenya. In all, the Lwoo number almost 2,500,000; they are also known as Nilotes (q.v.).

See also KENYA; AFRICA: *Ethnography (Anthropology): East Africa*; KAVIRONDO.

LUPERCALIA, an ancient Roman festival. Its rites were under superintendence of a corporation of priests called Luperci, whose institution is attributed either to Evander or to Romulus and Remus. But the festival itself, which was held on Feb. 15, contains no reference to these late fictions. It began with the sacrifice by the Luperci of goats and a dog, after which two of the Luperci were led to the altar, their foreheads were touched with a bloody knife and the blood wiped off with wool dipped in milk; then the ritual required that the two young men laugh. The sacrificial feast followed, after which the Luperci cut thongs from the skins of the victims and ran in two bands round the walls of the old Palatine city. A blow from the thong was supposed to cure sterility. The celebration of the festival went on until A.D. 494, when it was changed by Pope Gelasius I into the feast of the Purification.

The Luperci were divided into two colleges, called Quinctiliani (or Quinctiales) and Fabiani, from the gens Quinctilia (or Quinctia) and gens Fabia; at the head of each of these colleges was a magister. In 44 B.C. a third college, Luperci Iulii, was instituted in honour of Julius Caesar, the first magister of which was Mark Antony. In imperial times the members were usually of equestrian standing.

The ritual is apparently in honour of no god; Lupercus, whom authorities sometimes name, seems a mere invention, Faunus is a guess of the moderns. The Romans connected it with the Greek Lycaea (see LYCAON).

LUPINE, any plant of the genus *Lupinus*, which comprises about 300 species of annual and perennial herbaceous plants of the pea family (Leguminosae).

Native American species (*Lupinus perennis* and related species) with digitate leaves are found in moist fields and grassy hills

along the cool Pacific coast from British Columbia to northern Chile. A few species occur in the Mediterranean regions. Others, with single leaflets, are found in Brazil and eastern North America. Many of these are good subjects in the wild garden.

The species of which earliest mention is made is probably *L. termis*, which was cultivated by the ancient Egyptians. It is wild in some parts of the Mediterranean area and is extensively cultivated in Egypt. Its seeds are eaten by the poor after being steeped in water to remove their bitterness. The lupine of the ancient Greeks and Romans was probably *L. albus*, which is extensively cultivated in Mediterranean countries for forage, for soil enrichment and for its round flat seeds, which form an article of food. Yellow lupine (*L. luteus*) and blue lupine (*L. angustifolius*) are also cultivated in Europe as farm crops for green manure. *L. subcarnosus*, the state flower of Texas, is the bluebonnet.

WALTER SINGER

RUSSELL HYBRID LUPINE (LUPINUS)

The flowers, borne on long spikes above the dark-green foliage, are of the usual pealike form and range in colour from white, yellow and shades of pink to blue and purple. Grown chiefly for ornamental purposes in the U.S. and especially in England (where the climate is very favourable for them), the one- to five-foot plants are well adapted to borders and beds and are beautiful as cut flowers. Numerous garden hybrids of unknown parentage have been developed and are easily cultivated in any rich light sandy soil (neutral to acid) in full or partial sun. Perennials, including the fine Russell hybrids, should be seeded in summer and given adequate winter protection for flowering the following summer. The roots of young plants may be divided in very early spring. Annuals are best sown in place early in the spring. As with all leguminous plants, inoculation with nitrogen-fixing bacteria encourages root nodules and increased vigour.

HUGH SPENCER

WILD BLUE LUPINE (LUPINUS PERENNIS)

LUPINO, the name of the oldest theatrical family in England. The earliest traceable Lupino—who spelled his name "Lupino"—was flourishing, probably in Italy, about 1612 and billed himself as Signor Luppino. His descendant GEORGIUS GUILLEMUS (1652-

1693), a professional singer and reciter and also a puppetmaster, went to England as a political refugee. His son **GIORGUS CAROLUS** (b. 1662) became George Charles and was a performer and puppeteer at the age of eight. After the Restoration the Luppino family was granted a licence to play in the service of King Charles II.

John Rich had as an apprentice a small boy called **GEORGIUS RICHARD EASTCOURT LUPPINO** (1710–1787), the son of George Charles (1693–1725). Georgius Richard's son **THOMAS FREDERICK** (1749–1845), the first to spell the family name "Lupino," was a scenic artist and dancer.

The complicated family tree shows remarkably few intrusions of any calling unconnected with the stage. A particularly interesting member of the family, **GEORGE HOOK LUPINO** (1820–1902), had 16 children, at least ten of whom became professional dancers.

Almost the last of the old-style clowns was George Hook's eldest son, **GEORGE** (1853–1932), who was born in a dressing room of the Theatre Royal, Birmingham, Warwickshire, and was carried onto the stage in swaddling clothes when less than an hour old. He died a few hours after his last performance as the clown in a harlequinade with his son Barry as Harlequin. George's two brothers, **ARTHUR** and **HARRY**, were a famous turn in the music halls in the early years of the 20th century and Arthur, an incomparable animal impersonator, was chosen by Sir James Barrie to be the dog, Nana, in the first production of *Peter Pan*.

Of George's children, **BARRY** (1884–1962), besides being an actor, was the family archivist, and **STANLEY** (1894–1942) was a popular comedian, who died at the height of his powers and fame. Stanley's daughter **IDA** (b. 1918) became a film actress in Hollywood, Calif.

HENRY GEORGE (1892–1959), son of **HENRY CHARLES** (1865–1925), was a famous Cockney comedian better known under his stage name of Lupino Lane.

See Stanley Lupino, *From the Stocks to the Stars* (1934).

(A. H. D.)

LUPU, NICHOLAS (1876–1946), Rumanian politician, was born at Arsura, Rum. on Nov. 8, 1876. He started his career as a country doctor and entered politics in 1905. He played an important part during the peasant revolt in 1907 when, as prefect of the Falcu District, he succeeded in pacifying the peasants without having recourse to violent measures. In 1913 he was elected deputy and in 1919 he entered the Vaida-Voevod coalition cabinet as minister of the interior, representing, together with Ion Mihalache, the Peasant (Tsaranist) Party, of which Lupu became one of the principal leaders. During World War I, he visited Russia, France, England, Italy, and the United States on an active propaganda campaign on behalf of Rumania. During the succeeding period of Liberal government, Lupu remained in the background. He died Dec. 4, 1946.

LUPUS, PUBLIUS RUTILIUS, Roman rhetorician, flourished during the reign of Tiberius (A.D. 14–37), was the author of a treatise on the figures of speech, abridged from a similar work by the rhetorician Gorgias of Athens. In its present form it is incomplete. The work is valuable chiefly as containing a number of examples from the lost works of Greek rhetoricians. The author has been identified with the Lupus mentioned in the Ovidian catalogue of poets, and was perhaps the son of Publius Rutilius Lupus, a supporter of Pompey.

See editions by D. Ruhnken (1768), F. Jacob (1837), C. Halm in *Rhetores latini minores* (1863); monographs by G. Dzialas (1860 and 1869), C. Schmidt (1865), J. Draheim (1874), Thilo Krieg (1896).

LUPUS: see SKIN, DISEASES OF.

LUQMAN (LOKMAN), the name of two, if not of three, persons famous in Arabian tradition. The first was of the royal family of 'Ad, and is said to have built the great irrigation dam at Marib in Yemen and to have received the gift of life as long as that of seven vultures, each of which lived 80 years. The name of the second Luqman, called "Luqman the Sage," occurs in the Koran (31, 11). He wrote fables and proverbs with moral lessons. Two accounts of him are found. According to al-Masudi (i, 110) he was a Nubian freedman who lived in the time of David. According to some commentators on the Koran he was the son of Ba'ura,

one of the sons of Job's sister or maternal aunt. Joseph Derenbourg in his *Fables de Loqmân le sage* (1850) believes the name Luqman to be a translation of *Balaam*. The grave of Luqman was shown on the east coast of the Lake of Tiberias (Sea of Galilee), also in Yemen.

BIBLIOGRAPHY.—The so-called *Fables of Luqman* are known to have existed in the 13th century, but are not mentioned by any Arabian writer. They were edited by T. Erpenius (1615) and have been reprinted many times. For the relation of these to similar literature in other lands, see J. Jacobs' edition of Caxton's *Fables of Aesop*, vol. i (1889). See also bibliography in **FABLE**.

LURAY CAVERN, a large limestone cave in Page county, Va., U.S., near the town of Luray. The largest cave in the state, it embraces a total of 64 ac., of which 27 are open to the public. Since 1878 when it was discovered, wide natural corridors and the installation of indirect lighting have revealed its beauties to millions of tourists.

Luray cavern was formed millions of years ago by underground rivers and seepage of acid-bearing water through layers of limestone and clay. In time the clay was washed away, leaving only the limestone shell. Long after the formation of the cavern and after many stalactites had developed from the dripping of water impregnated with lime, the excavation was completely filled with glacial mud. This mud was charged with acid which eroded the dripstone and altered its shape. When the mud was subsequently removed by flowing water the older eroded forms remained alongside the new growth. This turbulent history has made the striking display of many-hued stalactites, stalagmites, columns and cascades one of the most remarkable in the world, including massive columns wrenched from their perpendicular position and hurled on the floor. Clear water, apparently containing no forms of life, is found in basins up to 50 ft. in diameter and 15 ft. in depth. The temperature in the cave remains at 54° F. (12.2° C.) throughout the year. Of particular interest is the "stalacpipe" organ which substitutes carefully selected stalactites for organ pipes.

(G. M. BE.)

LURGAN, a market town and municipal borough of County Armagh, N. Ire., 21 mi. S.W. of Belfast. Pop. (1961) 17,872. It dates from the reign of James I who in 1610 granted land to John Brownlow and his son William who formed an English colony there. By 1619 there were 42 houses and at the end of that century linen manufacture, still the chief industry, was established. James Logan emigrated from Lurgan in 1699 to become one of the founders of Pennsylvania. Lurgan castle (now Brownlow house) was built in 1836 by Charles Brownlow, created Baron Lurgan in 1839; the demesne with its lake is a public park. Born in the town were George William Russell, the poet and writer known as *Æ*, in 1867; and Field Marshal Sir John Greer Dill in 1881.

LURIA, ISAAC BEN SOLOMON ASHKENAZI (1534–1572), Jewish mystic and founder of the "new Cabala" (Lurianic Cabala), was born in Jerusalem of German parents. Because of his descent he was surnamed Ashkenazi ("the German"); his followers called him Ari ("Lion") or Ari ha-Qadosh ("the Holy Lion"). Many legends are told about his miraculous powers. He went to Egypt as a boy, after his father's death, and was brought up there by his wealthy maternal uncle. At the age of 17 a Cabalistic manuscript came into his hands, and, already deeply versed in rabbinic learning, he now began to study Cabala. He spent six years in isolation from his friends, occupied with mystical meditation, especially on the *Book Zohar*, which had just appeared in print (1558) (see **CABALA: The Zohar**). There followed a further period of ascetic life in retirement in a hut near the Nile. About 1570 he settled in Safed (Safad), the Palestinian centre of Cabala, where he immediately gathered a large circle of enthusiastic disciples around him. He expounded his teachings while walking with them through the fields and visiting the tombs of ancient teachers. After a stay of only a year and a half in Safed, he died of the plague on Aug. 5, 1572, at the age of 38.

His fame soon spread, especially through the letters written by Shlomo Dresnitz of Moravia to his friends in Europe and published under the title *Shivhe ha-Ari* ("The Praises of the Lion"). Luria wrote only a commentary on certain parts of the *Zohar*. His doctrine is contained in the works of his disciples, particularly of

Hayyim Vital and Joseph ibn Tabul. In addition, Luria's hymns for the three traditional Sabbath meals allude in ecstatic poetry to the essence of his mystical doctrine of God.

The basic themes of Lurianic Cabala are: (1) the doctrine of *zimzum* or the "retraction" of God prior to the act of creation; (2) *shevirat ha-kelim* or the catastrophic "breaking of the vessels"—i.e. of the lower *Sefirot* (divine potencies), and the resultant emergence of evil as a domain of its own; (3) *tiqqun*, or the eschatological "restoration" of God's unity with the help of the holy life of men. Luria elaborated in mythical imagery motifs found in early rabbinic sources and used formulae which derive, in part, from the 15th-century Jewish mystic Joseph Alkasti of Jativa (Spain). Unlike the earlier Cabalists, who regarded the transmigration (*gilgul*) of souls as a punishment for sins, Luria saw in it a chance for continuing the soul's task of self-perfection. This doctrine soon became part and parcel of popular Jewish belief. Under Luria's influence Jewish prayer and ritual assumed a distinctly mystical flavour, and became vehicles of meditation (*kavvanot*) in a highly technical sense. See also CABALA: 16th-Century Cabalists of Safed.

LURISTAN (LORESTAN), in the more restricted sense a former province of Iran, from 1938 to 1961 a (semiautonomous) part of the *ostan* (province) of Khuzistan and since 1961 a general governorship; in the wider sense, the "land of the Lurs," the region of western Iran which extends from the Iraq frontier and Kermanshah for about 400 mi. S.E. with a breadth of 100–140 mi., thereby separating the Khuzistan lowland from the interior uplands of Iran. The area is mountainous, having numerous ranges running north-west-southeast, some of which are still forested with a mixed oak-wood scrub. The central range, which is rarely identical with the main water divide, has many summits: Oshtoran Kuh, Kuh-e Garbosh, Zard Kuh, Kuh-e Gereh, Kuh-e Dinar (Dinah), rising to more than 14,000 ft. Several major rivers have their sources in these mountains; between the higher ranges are fertile plains, valleys and hilly districts, which are well watered and covered with lush pastures. Cultivation is scattered and rare, the main occupation still being pastoral nomadism.

The Lurs are thought to be of aboriginal stock with strong Iranian, Arabic and other admixtures. They speak a Persian dialect and are outwardly at least Shi'ite Muslims. The northern part of Luristan region, or Little Luristan, is inhabited by the Feili Lurs, divided into the Pishkuh (cismontane) Lurs in the east, and the Pushtkuh (ultramontane) Lurs in the west, adjoining Iraq. The Pishkuh area has kept the name Luristan and forms the province while Pushtkuh has become part of Kermanshah *ostan*.

Little Luristan was governed by independent princes of the Khurshidi dynasty, called atabegs, from 1155 to the beginning of the 17th century when the last atabeg, Shah Verdi Khan, was removed by Shah Abbas I. and the government of the territory given to Husain Khan, the chief of a rival tribe, with the title of vali. The descendants of Husain Khan retained the title.

The southern part of Luristan region, or Great Luristan, is composed of the Bakhtiari district inhabited by nomadic tribes (see BAKHTIARI) and the smaller districts of Kuhgalu (Kuhgiluyeh) and Mamaseni. Bakhtiari is divided between Khuzistan and Isfahan *ostans*, Kuhgalu is in Khuzistan and Mamaseni in Fars. Great Luristan was independent under the Fazlavieh atabegs from 1160 until 1424, and its capital was Idaj, now only mounds and ruins at Malamir, 60 mi. S.E. of Shushtar.

Luristan became well known as the result of archaeological finds made from 1929 onward: powerfully designed, technically competent bronzes (vessels, implements, personal adornments and particularly horse trappings), covering a period from 2600 B.C. to A.D. 800. The majority of the finest pieces were datable from the cuneiform inscriptions to between the 19th and 12th centuries B.C.

LURISTAN GENERAL GOVERNORSHIP stretches between the Der valley (used by the Trans-Iranian railway) and the upper Karkheh river, and northward to near Kermanshah and Nehavand. Its population (1961 est.) was 585,421 and area 11,737 sq.mi. The administrative centre is Khorramabad on the road from Ahvaz to Teheran and is connected also with Kermanshah by road. The produce of the province (as of the larger area) is mainly derived from the numerous flocks, rather than from agriculture. However, the main oil fields of southwest Iran also lie within the area of the Lurish tribes. (H. Bo.)

LUSAKA, the capital of Northern Rhodesia, Africa, and the seat of its government, is situated in the southeastern part of the country on a limestone plateau 4,200 ft. above sea level, 230 mi. N.E. of Livingstone. Its population in 1961 totaled 100,000, including 11,800 Europeans and 1,680 Asians. Cairo road, Lusaka's main thoroughfare, with its tree-lined boulevard and modern multistoried buildings, is regarded as one of the finest streets and shopping centres in the country. In the town are the legislative assembly building and offices as well as the Northern Rhodesia high court building, the British South Africa company's offices and the largest and most modern secondary schools in the country. Owing to its situation in an extensive limestone area, large quantities of cement are manufactured at Lusaka. It is also the centre of a major farming district which provides a large proportion of Northern Rhodesia's food. (C. L. Cs.)

LUSATIA (German LAUSTITZ, Lusatian LUZICA, from *lus*, "meadow"), the country of the Luzicane or Srbi (Sorbs), whom the Germans called Lausitzer Sorben or Wenden, in central Europe. It has been incorporated since 1949 within the territory of the German Democratic Republic, lying along the southern extremity of the German-Polish frontier and to a lesser extent along the northern frontier of Czechoslovakia.

In the 9th century, when the *limes Sorabicus* was the eastern frontier of the Frankish empire, the area settled by the Sorbs, a Slavonic people, extended westward to the Saale (Solawa) river. Lusatia was conquered by the Germans in 928 and lost by them to the Poles in 1002. By the treaty of Bautzen it was incorporated with Poland in 1018. It was reconquered by the Germans in 1033 and later partitioned between Meissen and Brandenburg. Lusatia was then submitted to a ruthless germanization: Sorbs were forbidden to settle in towns, to occupy any office or to learn any trade, those with farms that had good soil had their lands taken from them. Their situation improved somewhat when the Holy Roman emperor Charles IV in 1368–70 made Lusatia part of the lands of the Bohemian crown. In 1635, by the peace of Prague in the Thirty Years' War, Lusatia became part of the electorate of Saxony. It was again partitioned in 1815 by the congress of Vienna: while Saxony retained Upper Lusatia, with Bautzen (Budysin) Lower Lusatia was then given to Prussia, which incorporated Hoyerswerda (Hojerky) and its vicinity in the province of Silesia and Kottbus (Chosebuz) and its vicinity in Brandenburg.

By 1815 the western parts of historic Lusatia were completely germanized; but the marshy and sandy east offered but a small prize, and there the Sorbs retained their language, dress and customs. After 1871 intensive germanization started there too, mainly through the schools; and by 1880 the number of Sorbian-speaking people was reduced to 185,000 (90% Lutheran and 10% Roman Catholic). The German census of 1925 claimed that only 62,000 Sorbian-speaking people remained, but the leaders of the Sorbian national minority estimated their number at 260,000 in 1939.

In 1935 the Lusatian National council or Sorbska Domowina petitioned Hitler for the creation of a *Reichsgau Lausitz* of about 4,900 sq.mi. In 1938 the Domowina was dissolved by the Germans and its chairman, Pawel Nedo, arrested. The daily newspaper *Srbske Nowiny* was closed down and its publisher, the Rev. Jan Cyz, arrested. Both Nedo and Cyz survived the Nazi persecution and in 1945, at the end of World War II, reformed the Domowina. In 1946 the Lusatian National council appealed to the U.S., British, French and Soviet governments for "liberation from German rule."

Article II of the constitution of the German Democratic Republic (1949) guaranteed to the Sorbian people equal development of their language and culture. A daily newspaper *Nowa*

Doba appeared at Bautzen, and an Institute of Sorbian Culture was founded there. Sorbian was made the teaching language in a number of schools. (K. Sm.)

See H. Brückner, Beno Cyž *et al.*, *Die Sorben* (1964).

LUSHAI (LUSHEI), a Tibeto-Burman-speaking tribe numbering about 150,000 in the 1960s and inhabiting the mountainous tract on the Assam-Burma border known as the Lushai Hills, which extends between the Manipur River and the hills of Chittagong. Like the Kuki tribes, with which they have affinities, the Lushai practised shifting slash-and-burn cultivation and moved their villages at frequent intervals. Their migratory habits facilitated rapid Lushai expansion at the expense of weaker Kuki clans in the 18th and 19th centuries. Lushai villages are situated on the crests of hills or spurs and until the pacification of the country under British rule were fortified by stockades and contained as many as 500 houses. Every village, though comprising members of several distinct clans, was an independent political unit, ruled by a hereditary chief. All chiefs trace their descent from a common ancestor who lived in the early 18th century. The stratified Lushai society consisted originally of chiefs, commoners, serfs and slaves (war captives). Suppression of feuds and head-hunting under the British gradually changed the structure of Lushai society, but British policy until 1947 was to administer the Lushai Hills through the indigenous chiefs, whose number had by that time risen to 400. Since 1898 Christian missions had exerted strong influence, and education, partly coupled with Christianity, produced a new privileged class, whose members now work as government servants, physicians and teachers. See also CHIN; MIZO.

LUSHAI HILLS: see MIZO.

LUSIGNAN, a Poitevin dynasty that provided counts of La Marche and Angoulême in feudal France and kings of Jerusalem, Cyprus and Armenia. The castle of Lusignan (in the modern *département* of Vienne) is associated with the legend of Mélusine.

Early in the 10th century HUGH I, lord of Lusignan, was a vassal of the counts of Poitiers. Fifth in descent from him, HUGH VI the Devil, whose claim to the countship of La Marche by right of his mother came to nothing, went to Outremer (the crusader states of the east) in 1101 and was killed in battle at Ramleh in 1102. His grandson HUGH VIII the Brown, also a crusader (he was taken prisoner by the Muslims in 1165), had seven sons, three of whom followed the great fortunes of their house.

The Counts of La Marche.—Hugh VIII's eldest son and successor, HUGH IX the Brown or the Old (d. 1219), attached himself to his suzerain Richard I Coeur-de-Lion, king of England and count of Poitiers. Richard's successor John granted La Marche to Hugh in 1199 but alienated him in 1200 by taking his fiancée, Isabella of Angoulême, for himself, whereupon Hugh, with other great Poitevin barons, turned to John's enemy Philip II Augustus of France. His son and successor HUGH X of Lusignan (d. 1249) married Isabella of Angoulême, now John's widow, in 1220; made war on John's successor Henry III from 1219 to 1224; took Henry's side against France in 1230; and rebelled against Louis IX of France and his brother Alphonse of Poitiers in 1241–42, for which revolt he forfeited his principal strongholds. Yet his eldest son HUGH XI (d. 1260) succeeded as count of La Marche and of Angoulême (his mother's heritage), while in England the younger Lusignan half brothers of Henry III received notable advancement. Hugh XI's grandson HUGH XIII (d. 1303), however, pledged Lusignan and La Marche to Philip IV of France.

The Lusignans d'Outremer.—Hugh VIII's third son AMALRIC (see AMALRIC II, king of Jerusalem) went to Outremer, became constable of the kingdom of Jerusalem in 1179 and procured the marriage (1180) of his next younger brother, Guy of Lusignan, to Sibyl, elder sister of the leprosy king Baldwin IV. Count of Ascalon and Jaffa, Guy was regent of the kingdom for some months (1183–84) but quarreled with Baldwin IV and forfeited the right to be regent. On the death of Baldwin V, however, in 1186, Sibyl became queen and crowned Guy as king; but Raymond of Tripoli,

regent in Baldwin V's time, would not acknowledge him till 1187. Captured by Saladin's Muslims at the battle of the Horns of Hattin (July 1187) but released on parole in summer 1188, Guy was next faced with rebellion by Conrad of Montferrat and with the need to recover Acre (despite his parole) from the Muslims. Sibyl's death and Conrad's marriage to her sister Isabella (1190) further compromised Guy's royal title; and the contempt of the barons for Guy obliged Richard Coeur-de-Lion, who had long supported him, to recognize Conrad, the French king's nominee, as king of Jerusalem in 1192, on the understanding that Guy should be king of Cyprus. Guy died in his new kingdom in 1194.

Amalric succeeded Guy in Cyprus and became king of Jerusalem by marrying Isabella after the death, in 1197, of Henry of Champagne, whom she had married on Conrad's murder (1192). On Amalric's death (1205) his eldest son became HUGH I of Cyprus (d. 1218). This Hugh married Alice, Isabella's daughter by Henry of Champagne. Their son, HENRY I of Cyprus (d. 1253) left an infant son HUGH II (d. 1267), with whom the true male line of Lusignan in Cyprus became extinct. Henry I's younger sister Isabella of Cyprus, however, had married Henry of Antioch, and their son succeeded to Cyprus in 1267 as HUGH III (d. 1284), founding the line of Antioch-Lusignan. Hugh III was also crowned king of Jerusalem at Tyre in 1269, but returned to Cyprus in 1276 and failed in a last attempt on the mainland in 1279.

The empty title king of Jerusalem remained with Hugh III's successors in Cyprus. These were: his sons JOHN (d. 1285) and HENRY II (d. 1324), who was ousted by his brother Amalric prince of Tyre in 1306 but recovered his throne on Amalric's assassination (1310); their brother Guy's son HUGH IV (d. 1359), who abdicated in 1358; Hugh IV's son the crusader PETER I (d. 1369); Peter I's son PETER II (d. 1382); Peter I's brother JAMES I (d. 1398); James I's son JANUS (d. 1432); Janus' son JOHN II (d. 1458); John II's daughter CHARLOTTE (d. 1487), displaced in 1460 by her bastard half brother JAMES II (d. 1473); and James II's posthumous son JAMES III (d. 1474), whose mother was Caterina Cornaro (*q.v.*).

There were two kings of Armenia of the house of Antioch-Lusignan: GUY, son of Amalric prince of Tyre by King Hayton II's sister Zabel, king from 1342 to his murder in 1344; and Leo VI (V; d. 1393), son of Guy's brother John and king from 1374 to 1375.

LUSIN: see LU HSÜN.

LUSTRATION (Lat. *lustratio*, "purification by sacrifice"), a general term for the processes whereby an individual or a community was rid of ceremonial impurity (*e.g.*, bloodguilt, pollution incurred by contact with childbirth or with a corpse) or simply from the profane or ordinary state, which made it dangerous to come into contact with sacred rites or objects. The methods varied from sprinkling with or washing in water, especially (though not always) running water, through rubbing with various substances such as clay, bran or blood, or through bathing in the sea, to complicated ceremonies, some of which involved confession of sins, a form of purgation found in many cultures. There was also fumigation with various substances, including sulfur. The rites of swinging, either in person or by suspending surrogate objects on trees, probably aimed at purification by air or wind. A homicide had the blood of a pig poured over him, perhaps to make the ghost of his victim imagine that his blood had in turn been shed and vengeance thus taken.

When a community was to be purified, either from collective guilt or from the accumulated ill luck and ill doing of a period of time, the usual Greek method seems to have been to lead through the village certain persons or animals capable of absorbing the pollution. Notable examples were the *pharmakoi* ("human scapegoats") who, either to cure plague or other calamities (in Ionia) or as an annual precaution (at Athens), were led through and out of the city, after which some pretense was made of killing and burning them, thus destroying the contagion. The Romans led their purifying materials around the person or community in question: a woman supposed mad is advised *circumferri*, to have appropriate remedies carried around her. Many noteworthy public rites were of this kind, such as the Lupercalia (*q.v.*); around the

original Palatine settlement), the Ambarvalia (*q.v.*; around the fields of a landholder, or anciently around the *ager Romanus* itself) and the *amburbium* ("around the city"), in all cases tracing a magic circle to keep evil out and radiate blessings in, especially fertility.

See N. M. P. Nilsson, *Geschichte der griechischen Religion*, 2 vol., 2nd ed. (1955); W. Warde Fowler, *Religious Experience of the Roman People From the Earliest Times to the Age of Augustus*, pp. 209–218 (1911). (H. J. R.)

LUTE, a plucked stringed instrument, originally brought to Europe from the near east; much used in European music from the middle ages to the 18th century, it was still in use in many Arab countries in the second half of the 20th century. The distinguishing feature of the lute is the shape and complex structure of its body, which resembles half an almond or filbert, having a vaulted or barrel-shaped back, convex in each direction and wider toward the bottom end. The back was composed of several ribs or "staves," which were bent over a prepared mold; the edges were brought together and glued, afterward being lined with strips of paper or parchment. Much attention was paid to the shaping and proportions of the mold. The earliest European lutes followed the contemporary Arab pattern in having four strings; they were played with a quill plectrum. By the middle of the 14th century the strings had become pairs, or "courses." Existing representations of the lute in the 15th century show it then to have had a body usually composed of nine staves and five courses of strings (*i.e.*, nine strings, the lower courses in pairs, the highest single) laid on a short, flat neck carrying seven gut frets. The soundboard of the lute contains a circular sound hole, set nearly central, with a perforated ornament—the "rose"—cut in the soundboard wood. The bridge is of the tension type, glued directly to the lower part of the soundboard. The head or pegbox is sharply reflexed and turns back from the nut at the top of the finger board at nearly a right angle. The purpose of this reflection seems to be twofold: to reduce over-all length on this rather large instrument so that there is easier access to the pegs in tuning, and to ensure firm bearings at the nut for the very thin, slack double gut strings.

During the 15th century the use of the plectrum in playing was generally abandoned in favour of the fingers of the right hand; and by the 16th century the classic form and stringing of the lute were established, and the great Bolognese and Venetian schools of makers had arisen. These makers—Laux and Sigismond Maler, Hans Frei, Nikolaus Schonfeld and the Tieffenbruckers—by their fine workmanship and the tonal proportions of their instruments contributed much to the popularity of the lute in the late Renaissance and paved the way for its extensive and noble literature of solo music (fantasias, dance movements, chanson arrangements), song accompaniments and consort music. The neck was lengthened to take 9, later 10, semitone frets, and the standard stringing was six courses tuned to G c f a, d' g'. Its technique was systematized and its music expressed in tablature, a form of notation representing not the musical sounds played but the strings and fret positions used in order to produce those sounds. These positions were indicated by a stave of horizontal lines representing the courses of the lute, letters or figures being placed on these lines to

denote the fret to be stopped by the left hand and the strings to be played by the right hand.

Toward the end of the 16th century further bass strings were added, the neck and head being enlarged to take them. These "diapasons," which reached four in number, were usually tuned to a diatonic scale downward from the sixth course. From about 1600, modifications in the tuning were introduced by French lutenists and by about 1630 had generally replaced the "old tuning." At the same time further diapasons were added, the resulting instrument being known as the "French lute." This was primarily a solo instrument. Its repertory required a highly mannered and ornamented style of performance and a new technique of broken chords and slurred notes that had a marked influence on the 17th-century French harpsichord composers. With the introduction of the additional diapasons, problems of tonal balance arose and the lower strings were often lengthened beyond the normal nut and carried by means of an extension of the neck to a separate nut and pegbox.

The theorbo or "theorboed lute" was often a large instrument that continued to use the "old tuning" and had the diapasons carried on a second head. Because of its greater string length, which made only the simplest chordal playing practicable, it was mainly used for *continuo* purposes. A larger form of theorbo, the *chitarone*, was developed in Rome about 1600; its diapasons were carried on a huge neck extension, the whole instrument often being 6 ft. in length. With a sonority approaching that of a contemporary harpsichord, it was capable of holding its own in the chamber ensembles of the 17th century. (E. Ha.)

LUTETIUM is a silvery metallic element of the rare earth group. It reacts readily with oxygen, water, acids and most non-metals. Of all the rare-earth metals, lutetium is the hardest, is the most dense (9.842 g. per cubic centimetre for the hexagonal close-packed structure) and has the highest melting point, 1,652° C. There are two naturally occurring isotopes: Lu^{175} (97.4%, in abundance) is stable and Lu^{176} (2.59%) is radioactive with a half life of 2.2×10^{10} years. The radioactive isotope is used to determine the age of meteorites relative to that of the earth.

Lutetium was discovered by C. A. von Welsbach and G. Urbain working independently in 1907–08. Urbain derived the name for the element from *Lutetia*, the Roman name for Paris. The element, one of the rarest of the rare earths, occurs in many minerals, the most important of which are gadolinite, euxenite, xenotime and samarskite. It is also found in the products of atomic fission. Until the development of ion exchange techniques during World War II, lutetium was separated and purified by fractional crystallization and precipitation. The metal has been prepared by thermoreduction of the anhydrous halides by alkali or alkaline earth metals.

The symbol of lutetium is Lu, the atomic number 71 and atomic weight 174.97. The thermal neutron absorption cross section is 108 barns and the ionic radius is 0.848 Å. The element behaves as a typical trivalent rare earth, forming a series of white salts such as Lu_2O_3 , $\text{Lu}_2(\text{SO}_4)_3$ and LuCl_3 . The colourless solutions of Lu^{3+} ions show no discrete absorption bands in the ultraviolet and visible regions of the spectrum; analysis is best carried out by emission spectroscopy. The ion is diamagnetic since there are no unpaired electrons. See RARE EARTHS. (Lb. B. A.)

LUTHER, MARTIN (c. 1483–1546), the German religious Reformer who began the Protestant Reformation, was born on Nov. 10 (certainly), 1483 (probably), at Eisleben in Thuringian Saxony. His parents, Hans and Margaret Luther, had moved there from Möhra, and soon moved on to Mansfeld where Hans Luther worked in the copper mines, prospering enough to be able to rent several furnaces and to be among the councilors of the little town in 1491. Martin's few recollections of childhood which have survived reflect a sombre piety and strict discipline common in that age. His schooling seems to have been unremarkable: the Latin school at Mansfeld, a year at a school in Magdeburg (run by Brethren of the Common Life) and at Eisenach in his 15th year, where he made valued older friends. In April 1501 "Martinus Luther ex Mansfeld" matriculated in arts at the University of Erfurt, one of the oldest and best attended universities in Germany. There he

PROPERTY OF ERIC HALPFENNY

LUTE BUILT BY HANS FREI, ABOUT 1550

talked long and enough to be nicknamed "the Philosopher," and played the lute. He took the usual arts course and graduated B.A. in 1502. He took his M.A. in 1505 and was placed second among 17 candidates. In an age when few students got as far as the M.A. he had fulfilled his parents' hopes. Like many other parents of his time, Hans Luther did not intend his son to enter the religious life but to become a lawyer, and he paid cheerfully enough for the expensive textbooks when Martin began legal studies. He was chagrined to learn that his son, without consulting his parents, had decided to enter religion and had sought admission to the house of Augustinian Hermits in Erfurt.

Brother Martin Luther.—On the reason for the decision the evidence is scanty. In the later, not always reliable, *Tischreden* ("Table Talk") it is related that on July 2, 1505, Luther was returning from a visit to his parents when he was overtaken by a thunderstorm near the village of Stotternheim and cried out in terror, "Help, St. Anne, and I'll become a monk." Luther himself in his *De votis monasticis* ("Concerning Monastic Vows," 1521) says "not freely or desirously did I become a monk, but walled around with the terror and agony of sudden death, I vowed a constrained and necessary vow." He sold his books, keeping back his Virgil and Plautus, and on July 16, 1505, bade farewell to his friends.

In joining the eremitical order of St. Augustine, Luther had joined a mendicant order of importance, which by the middle of the 15th century had over 2,000 chapters. In 1473 Andreas Proles carried through a reform and the house at Erfurt accepted the strict, observant interpretation of the rule, with Proles as vicar-general. Under his successor, Luther's mentor, Johann von Staupitz, a revised constitution was made in 1504. Luther made his profession in Sept. 1506 and was then prepared for ordination. He was ordained priest in April 1507 and his first Mass took place at the beginning of May. He had studied a treatise on the canon of the Mass by the famous Tübingen nominalist Gabriel Biel (d. 1495), and approached the ceremony with awe. To this occasion his father came with a group of friends, and Luther took this first opportunity to explain personally the imperious nature of his vocation. His father's disgruntled retort, "Did you not read in Scripture that one shall honour one's father and mother?" struck deep into his memory.

Luther was selected for advanced theological studies, under Johann Paltz and Johann Nathin. Like his other university teachers, Arnold von Usingen and Jodocus Trutvetter, they were nominalists (see NOMINALISM) of the "modern" way of William Ockham. In 1508 Luther went to the new University of Wittenberg (founded 1502), where, though Ockhamism had a foothold, the *via antiqua* was championed by the redoubtable Martin Pollich. The little town was a contrast to Erfurt, but at least the university was young and forward looking and to its comparative remoteness Luther would one day owe his life. The *Schlosskirche* of All Saints was closely connected with the university, and on both the elector of Saxony, Frederick III (*q.v.*) the Wise (head of the Ernestine branch of the house of Wettin) lavished generous patronage. In March 1509 Luther took the degree of *baccalaureus biblicus* at Wittenberg, returning to Erfurt for his next degree, of *sententiaris*. He had begun teaching with a course on the *Nicomachean Ethics* of Aristotle, and now began his career as a theologian with lectures on the *Sententiae* of Peter Lombard (1509). Some of his notes have survived, and if their theology is unexciting there is apparent an acid vehemence at the intrusion of philosophy and above all of Aristotle into the realm of theology.

Johann von Staupitz, vicar-general of the German Augustinians, was of moment in Luther's career as his teacher, friend and patron. Staupitz seems to have been theologically trained as a Thomist in the *via antiqua*, but was also influenced by the Augustinian tradition of his order, while his theology shows elements derived from the conflation in the late 15th century of the *devotio moderna* with German mysticism (Heinrich Suso, Johann Tauler). His attempt to revive stricter discipline and to unite the observant and conventual Augustinians in Germany led to dispute, and Luther was one of two monks chosen to present the appeal at Rome of some dissident houses. He made the journey, the longest of

his life, probably late in 1510, and his Teutonic earnestness was shocked at the Italianate levity of the Roman clergy and by worldliness evident in high places. The appeal failed, and Luther returned to become a loyal supporter of Staupitz.

Staupitz became interested in his gifted pupil and, perhaps alarmed by his introspectiveness, encouraged him to proceed to his doctorate and to a consequent public teaching career. Luther took his D.D. on Oct. 12, 1512, at the hands of the dean, Andreas von Karlstadt. The degree was important for Luther, with its implications of public responsibility, and was soon joined with the duties of a professor when he succeeded Staupitz in the chair of biblical theology. This was his lifelong calling, and the exposition of the Bible to his students was a task which called forth his best gifts and energies, one which he sustained until ill health and old age made him relinquish it at the end of his life. In between lectures, so to speak, he began the Protestant Reformation.

Meanwhile, Luther's religious and theological difficulties became acute. He had entered on the search for evangelical perfection with characteristic and serious zeal, and sought exactly to fulfill the rule of his order. Nonetheless, he soon found himself in deep waters, struggling against uncertainties and doubts, unhappily bearing a crippling burden of guilt, which neither the sacramental consolations of the church nor the wise advice of skilled directors was able to assuage. This distress, which had its centre in his unquiet conscience, brought him into states of anxiety and despair. Nor were his difficulties lessened by the stress of the Ockhamist theology, which encouraged an extroverted moralism, throwing stress on the human will, and leaving alarming points of uncertainty at the very points where Luther needed most to be reassured. Temptation (*Anfechtung*) was to become an important word for Luther's theology, a term which suggests the fight for faith, of which Staupitz could say that such experiences were meat and drink to Martin Luther. These inward, spiritual difficulties were enhanced by theological problems.

"The Righteousness of God."—At the entrance to the world of Pauline thought Luther was halted, the road blocked by a word which intensified his difficulties to an almost intolerable degree. This was the conception of the "righteousness of God" (*justitia Dei*). His sombre childhood piety had made him intensely aware of God's judgment, and as a lecturer in the arts faculty at Wittenberg he had had to expound the Hellenic conception of justice, as he found it in book 5 of the *Nicomachean Ethics* of Aristotle. Encouraged by the use of *justitia* in Gabriel Biel and other nominalists, he thought of God's justice as being primarily the active, punishing severity of God against sinners. It was for him a final aggravation of his trouble that in Rom. i, 17 it is asserted that the justice of God is revealed in the gospel. Thus, the divine demand was shown as extending beyond outward obedience to the law, revealed in the commandments, to purity of heart, to inward motive and intention, so that grace itself became a demand and an exaction. Such a God could be feared but not loved, could be obeyed out of constraint but never with that happy spontaneity which Luther felt to be of the essence of Christian obedience.

To Luther's sense of failure was added the feeling of hypocrisy, which drove him to the edge of what the moral theologians described as "open blasphemy." In 1545, in the celebrated autobiographical fragment which he prefaced to his complete works, he thus described his feelings:

For however irreproachably I lived as a monk, I felt myself in the presence of God to be a sinner with a most unquiet conscience, nor could I believe that I pleased him with my satisfactions. I did not love, indeed I hated this just God, if not with open blasphemy, at least with huge murmuring, for I was indignant against him, saying "as if it were really not enough for God that miserable sinners should be eternally lost through original sin, and oppressed with all kind of calamities through the law of the ten commandments, but God must add sorrow on sorrow, and even by the gospel bring his wrath to bear." Thus I raged with a fierce and most agitated conscience, and yet I continued to knock away at Paul in this place, thirsting ardently to know what he really meant.

Thus, the dilemma. Illumination came at last, as in prayer and meditation he pondered the text, examining the connection of the words.

At last I began to understand the justice of God as that by which the just man lives by the gift of God, that is to say, by faith, and this sentence, "the justice of God is revealed in the Gospel," to be understood passively, that by which the merciful God justifies by faith, as it is written, "The just man shall live by faith." At this I felt myself to have been born again, and to have entered through open gates into paradise itself.

There has been great controversy about this inner conflict, but it seems certain that there was for Luther just such a crisis as he later described and that it was resolved in the manner he narrates. There has also been argument about the novelty of this discovery. There is in fact a profound difference between the Hellenic conception of distributive justice and the biblical doctrine of the righteousness of God as a divine, saving activity displayed in the field of history and of human experience, and Luther had penetrated deeply into the Pauline vocabulary at this point. The accuracy of Luther's memory about this, and indeed, his integrity, have sometimes been impugned, notably by H. Denifle, but the verdict of another Catholic historian, J. Lortz, may stand: that if the discovery were not new, it was at any rate "new for Luther."

Had Luther not written this account, it would have been necessary to conjecture something like it, to account for the new importance which he gave to justification by faith, a priority it retained in the new theological framework of Protestantism. This became for him the nerve of the gospel, that salvation is to be thought of primarily in terms of grace, and of a divine gift; that God's free, forgiving mercy is displayed in Jesus Christ; that the conscience, forgiven and cleansed, may be at peace, and that the soul, free from the burden of guilt, may serve God with a joyful, spontaneous, creative obedience. In his translation of the Bible Luther came to add "alone" after the word "faith" in the verse "For we hold that a man is justified by faith apart from works of law" (Rom. iii, 28) because he felt it to be demanded by the German language. The word "alone" or "only" was retained by the Reformers after him because it seemed to safeguard this important doctrine against such perversions as might seem to make salvation dependent on human achievement or a reward for human merit.

This experience ought not perhaps to be isolated, for Luther speaks of other problems of vocabulary (e.g., the conception of repentance, *poenitentia*), and it cannot be assumed that this was for him a catastrophic personal experience such as befell St. Augustine in the garden at Milan or John Wesley at Aldersgate street. About the date of the occurrence there has been much controversy. The publication of Luther's early lectures led naturally to the examination of these first fruits of the young professor. The view argued most persuasively by Erich Vogelsang that it must have occurred during the period of Luther's first lectures on the Psalms (1513-14) has been damagingly criticized, but Vogelsang drew attention to Luther's use of the many-sided allegorism of the middle ages, which often found three or four levels of meaning in a single text; to Luther's concentration on the one historical meaning; and to the Christocentric core of Luther's theology of justification. Many will think that the illumination must have come to him before his fine and impressive lectures on the Epistle to the Romans (1515-16).

Something depends on how the discovery itself is assessed: if it was a discovery that justification is a gift, that it is to be taken passively rather than actively, then (as the reference to Augustine's *De spiritu et littera* suggests) Luther was hardly moving beyond the Augustinian framework. If on the other hand it was the more mature discovery of the relation of saving faith to the word of God then it must be placed later, perhaps in 1518-19; the trend of scholars such as Wilhelm Link, U. Saarnivaara and Ernst Bizer has been in this direction and to emphasize how Luther's thinking was stimulated and redirected by the urgent pressure of the church struggle which began in 1517.

The net gain of this chronological discussion has been to demonstrate how important is the whole period of Luther's development from 1509 to 1521, and that his technical vocabulary and the categories of his theology were in movement throughout the whole of this period. Certainly the great courses of lectures on the

Psalms (1513-15), on Romans (1515-16), Galatians (1517) and Hebrews (1517-18) show the growing richness and maturity of his thought. Meanwhile, his other duties had accumulated. From 1511 he had been preaching in his monastery and in 1514 he became preacher in the parish church. This pulpit became the centre of a long and fruitful preaching ministry where Luther expounded profoundly and beautifully the Scriptures for the common people and related them to the practical context of their lives. Within his order, he had become prior, and then in May 1515 district vicar over 11 other houses. Thus he became involved in a world of practical administration and of pastoral care which gave him valuable experience, standing him in good stead in later years when a large part of his vast correspondence would be concerned with the care of the German churches and the cure of needy souls.

The new University of Wittenberg found it must take sides in an academic crisis which faced the European universities of that day, the tension between an old and a new academic program. Before Luther's advent Martin Pollich had shown himself hospitable to humanist influences, despite his preference for Thomism. Now Luther took the lead in inaugurating a new program, involving the displacement of Aristotle and the scholastic theologians by a biblical humanism which turned to the direct study of the Bible, using as tools the revival of Greek and Hebrew and a renovated Latin and as a dogmatic norm the "old Fathers" and especially St. Augustine. Such a program Luther planned with the help of his senior colleague, Andreas von Karistadt, and his young friend Philipp Melancthon. In Feb. 1517 he penned a series of theses against the scholastic theologians, which he offered to defend at other universities, and though the attempt to export the Wittenberg program met with no success he could write in May that the battle was won in Wittenberg—"our theology, and that of St. Augustine reign." But if his theses remained dormant, a very different fate awaited those which he wrote later in that same year. He could hardly have thought that these would fire a train which would explode the western Christian world.

Indulgence Controversy.—The nature and scope of indulgences had been more and more defined during the later middle ages, but there was still an element of that dogmatic uncertainty which J. Lortz has called a theological weakness of the age. Indulgences were the commutation for money of part of the temporal penalty due for sin, of the practical satisfaction which was a part of the sacrament of penance. They were granted on papal authority and made available through accredited agents. Not at any time did they imply that divine forgiveness could be bought or sold, or that they availed for those who were impenitent or unconfessed. But during the middle ages, as papal financial difficulties grew more complicated, they were resorted to so often that the financial house of Fugger had to superintend the *secretum negotium*.

The way was open for further misunderstanding when in 1477 Pope Sixtus IV extended their authority to souls in purgatory. The appeal to cupidity and fear, the pomp and circumstance with which these indulgences were attended, the often outrageous statements of some indulgence sellers were a matter of complaint. Luther himself had frequently preached against these things, for his patron, the elector Frederick, had amassed a great collection of relics in the castle church at Wittenberg, to which indulgences were attached. But the immediate cause of Luther's public protest was an indulgence which Frederick had prohibited from his lands, though it was available in nearby territory. This was a jubilee indulgence, offering special privileges, the ostensible purpose of which was the rebuilding of St. Peter's in Rome. In fact by a secret arrangement, half of the German proceeds were to go to the young Albert, archbishop of Mainz, who was up to the ears in debt owing to his rapid promotion to a number of high ecclesiastical offices.

Of this Luther knew nothing until some time afterward. The provocation came for him in the extravagant utterances of an old, tried hand at this kind of thing, the Dominican Johann Tetzel (q.v.). With these claims in mind, Luther drew up the 95 Theses, "for the purpose of eliciting truth," and fastened them on the door of All Saints church, Wittenberg, on Oct. 31, 1517, the eve of All

Saints' day and of the great exposure of relics there. These were tentative opinions, about some of which Luther himself was not committed. They did not deny the papal prerogative in this matter, though by implication they criticized papal policy; still less did they attack such established teaching as the doctrine of purgatory. But they did stress the spiritual, inward character of the Christian religion, and the 1st thesis, which claimed that repentance involved the whole life of the Christian man, and the 62nd, that the true treasure of the church was the most holy gospel of the glory and the grace of God, showed the author's intention. The closing section attacked the false peace, that "security" which as a young lecturer he had so often attacked, of those who thought of divine grace as something cheaply acquired and who refused to recognize that to be a Christian involved embracing the cross and entering heaven through tribulation. Luther sent copies of the theses to the archbishop of Mainz and to his own ordinary. But here the invention of printing intervened: it enabled copies to be circulated far and wide, so that what might have been a mere local issue became a public controversy discussed in ever widening circles.

The archbishop of Mainz, alarmed and annoyed, forwarded the documents to Rome in Dec. 1517, with the request that Luther be inhibited, at the same time reprimanding the indulgence sellers for their extravagance. At this time it seemed to many that this was just another squabble between religious orders, the Dominicans and the Augustinians. Colour was given to this by the countertheses prepared by the theologian Konrad Wimpina which Tetzel defended before a Dominican audience at Frankfurt at the end of Jan. 1518. When copies of these reached Wittenberg in March they were publicly burned by excited students. At Rome the pope merely instructed the vicar-general of the Augustinians, Gabriel della Volta, to deal with the recalcitrant monk through the usual channels, in this case through Staupitz. Luther himself prepared a long Latin manuscript with explanations of his 95 theses, publication of which was held up until the autumn of 1518; it is a document of some theological importance, and shows how far from superficial had been Luther's original protest. Meanwhile, the chapter of the German Augustinians was held at Heidelberg, April 25, 1518. Luther was relieved of his extra duties as district vicar, in the circumstances a great relief and intended as such. He found great comfort in the support of his friends, and was himself in great form, winning over two young men, Martin Bucer (*q.v.*), a Dominican, and the future scholar Theodor Bibliander.

At this period Luther's theology was very specially a "theology of the cross"; *i.e.*, a theology that stressed the revelation of Christ on the cross, which seems foolishness to the wisdom of the world and which is opposed to the natural theology of divine power and majesty, attacked by Luther as a scholastic "theology of glory." Important for him at this time was the inward religion of Johann Tauler and of the short 14th-century mystical tract which he himself edited and published (1516-18), the *Theologia Germanica*; in these months, therefore, he lays great stress on the need for the Christian to share the cross of Christ, in suffering and in temptation. These stresses were to fall into the background of Luther's developing theology but were to remain important for the radical Reformation in the following years, for which the *Theologia Germanica* would be an important and seminal document.

During Luther's absence, and perhaps catastrophically, his senior colleague, Karlstadt, had taken action which was greatly to widen the scope and publicity of the controversy. The scholar Johann Eck (*q.v.*) of Ingolstadt, a man with a zest for disputation and of some learning, with whom Luther was already in friendly contact through their common friend Christopher Scheuerle, became involved in the controversy. He had penned some observations on the 95 Theses, written for his friend the bishop of Eichstätt, and these manuscript observations, the so-called *Obelisci*, reached Wittenberg shortly before Luther went off to his chapter at Heidelberg; Luther himself replied with a few *Asterisci*, but Karlstadt, concerned to defend the Wittenberg program, sprang into the fray with 380 theses, adding another 25 before publication, in some of which Eck was impugned. The Dominicans continued to press for Luther's impeachment, and proceedings against

him for heresy began to move slowly in Rome. Luther himself did not improve matters by publishing a bold sermon on the power of excommunication which made it clear that here was not a man who would accept unquestioned whatever might be decided by the pope in terms of some undefined plenitude of power.

Augsburg Interview, 1518.—A citation to Rome was sent to the cardinal Cajetan, a renowned Thomist, at Augsburg. But at this perilous moment politics fatefully intervened, and the period when the Luther affair might have been swiftly, drastically disposed of without wider disaster to the church was whittled away by considerations of policy. The elector Frederick, as one of the seven prince electors of the Holy Roman empire, was most important to the pope, in view of the imminent choice of a new emperor, and the pope could not afford to antagonize him. The result was that Luther was bidden to a personal interview with Cajetan at Augsburg. He arrived there on Oct. 7 with an imperial safe-conduct. The discussion had moved from indulgences to the discussion of the relation between faith and sacramental grace, but a wrangle developed between the two theologians about the meaning of the "treasure" of merits which the papal definition of Sixtus IV said that Christ had acquired, and the incensed cardinal dismissed Luther from his presence, telling him to stay away unless he would unconditionally recant.

While Luther waited uneasily the Saxon councilors reported rumours that he would be taken in chains to Rome. Eventually, bundled through a postern by his friends, he fled the city. Now he wrote an appeal from the pope to a general council and a full defense of his actions to his prince. Cajetan also lost no time in denouncing Luther to Frederick, who was in something of a dilemma, though it counted much for Luther that he had the admiring friendship of the elector's secretary, the humanist Georg Spalatin. At this time, too, the Wittenberg theological faculty addressed the prince on his behalf, pointing out that the fate of the university and its reputation would be involved in Luther's disgrace. At one moment, it seemed that Luther might have to depart, perhaps for France or Bohemia. There then appeared a papal diplomat, a German, Karl von Miltitz, who applied "stick and carrot" tactics to the elector, dangling before him at one moment threats against Luther and at the next the signal compliment of the golden rose. Miltitz promised more than he could possibly perform, and after an interview with him at Altenburg, in Jan. 1519, Luther sensed this; he retained a lively and unimpressed distrust of this sentimental and lachrymose arbiter. A papal definition about indulgences, issued at Cajetan's request, would seem to show that Luther had indeed put his finger on some fatal ambiguities.

Leipzig Disputation, 1519.—At Augsburg Luther had been in touch with Eck and arrangements went forward for a public disputation at Leipzig in the summer. This was in the first place a debate between Eck and Karlstadt, though Luther was Eck's ultimate objective, but the hostility toward the Reformer on the part of George, duke of Saxony (head of the Albertine branch of the house of Wettin and the elector Frederick's first cousin), raised difficulties about Luther's participation. Eventually it was arranged that Eck should debate with the two Wittenberg theologians in turn, in the castle of the Pleissenburg, Leipzig, at the end of July. There was a preliminary pamphlet skirmish. The issue between Eck and Karlstadt was the Augustinian doctrine of grace and free will, and Karlstadt wished to meddle neither with indulgences nor with papal authority. Now among the preliminary matters that of the origin of the papal power was raised and so Luther turned to a study of church history and canon law in the fateful weeks before the debate. A large contingent from Wittenberg attended, and in the presence of theologians from both universities, Duke George and notables of church and state, the debate began. Eck showed some skill in maneuvering Luther into a position where he cast doubt on the authority of the great German Council of Constance, and defended some of the propositions of John Huss. Leipzig was a part of Germany with a strong feeling against Bohemia, and the admission was received as damaging, giving ground for Eck's loud boast that the disputation had been his personal triumph.

Eck was able to go off to Rome with new prestige to give sharpness to the process of Luther's official condemnation. Luther had now to examine the further implications of his actions to date, in relation to the authority of the church, of councils and of Scripture; his correspondence shows that he was reaching something like a crisis in his attitude to papal authority. There had been a small pamphlet war after the disputation which made it plain that there was strong support for Luther among the humanists such as Willibald Pirckheimer and the brothers Bernhard and Konrad von Adelsmann in Germany, and Joachim Vadianus and Huldreich Zwingli in Switzerland. Luther himself became involved in controversy with three diverse theologians of Leipzig, Hieronymus Dungersheim, Hieronymus Emser and Augustinus Alveldus, and if he now wrote in the vernacular with increasing power and violence, his polemical writings reveal also his deep perceptions of the issues between himself and contemporary theology. Two Catholic universities, strongholds of tradition, Cologne and Louvain, now condemned Luther's teaching. But polemic was not Luther's main concern, and his fine treatise *Von den guten Werken* ("Of Good Works"), issued in June 1520, is an important exposition of the ethical implications of justification by faith, a tract that deserves to be associated with the more famous tract on Christian liberty of the next months. On June 15, 1520, appeared the papal bull *Exsurge domine* against 41 articles of Luther's teaching, followed by the burning of Luther's writings in Rome. Eck and the humanist diplomat Girolamo Aleandro were entrusted with the task of taking the bull to the cities of Germany.

Treatises of 1520.—Eck and Aleandro were alarmed to find how swiftly German opinion had moved to Luther's side. Eck had to seek refuge in Leipzig from physical violence—a contrast to his treatment the year before. Aleandro did what he could in agitated correspondence to shock the *curia* into realizing the grave danger facing the church in Germany. Luther's friends, notably Spalatin and Philipp Melancthon, aware how precarious was his position, sought to moderate his violence, but he now moved well beyond their horizon. The result was the defiant tracts of the summer of 1520. The first, the real manifesto, was his *An den christlichen Adel deutscher Nation* ("Appeal to the Christian Nobility of the German Nation"), addressed to the rulers of Germany, princes, knights, cities, under the young emperor Charles V. In the present crisis, when the spiritual arm had refused to take in hand the amendment of the church and the often expressed grievances of the German people against Rome, it was for the secular arm to intervene and call a reforming council. The document was ill arranged and tailed off, but it found deep response among sections of the nation, and in the next months Luther was carried along with the tide of national resentment against Rome.

His second treatise, *De captivitate Babylonica ecclesiae praeiudicium* ("A Prelude Concerning the Babylonish Captivity of the Church"), intended for clergy and scholars, was an act of ecclesiastical revolution. It inevitably estranged many moderate humanists, for it reduced to three the seven sacraments; denied Mass and attacked transubstantiation, made vehement charges against papal authority and asserted the supremacy of Holy Scripture and the rights of the individual conscience. The third work, dedicated to the pope, was as a still, small voice after the uproar, a minor classic of edification, *Von der Freiheit eines Christenmenschen* ("Of the Liberty of a Christian Man"), which made clear the ethical implications of justification by faith, and showed that his thought and his public actions were connected by a coherent theological core. On Dec. 10, 1520, the students lit a bonfire before the Elster gate in Wittenberg, and as they fed the works of the canonists to the flames Luther added the papal bull against himself with suitable imprecation.

In Jan. 1521 the pope issued the bull of formal excommunication (*Decet Romanum pontificem*), though it was some months before the condemnation was received throughout Germany. Meanwhile the imperial diet was meeting at Worms, and there was a good deal of lobbying for and against Luther. In the end Frederick the Wise obtained a promise from the emperor that Luther should not be condemned unheard and should be summoned to ap-

pear before the diet. This enraged Aleandro, who asserted that the papal condemnation was sufficient and that the secular arm had only to carry out its orders. It also alarmed Luther's friends, who did what they could to dissuade him. Luther was firm in his determination to go, and began the journey in April 1521, undeterred by the news, on the way, that the emperor had ordered his books to be burned. What was meant to be the safe custody of a heretic turned out to be something like a triumphal procession, and when Luther entered Worms on April 16 he was attended by a cavalcade of German knights and the streets were so thronged as to enrage his enemies.

Diet and Edict of Worms, 1521.—In the early evening of April 17, 1521, Luther appeared before the notables of his world and faced the young emperor Charles V, whom he found cold and hostile (see CHARLES V). A pile of writings lay before him, but when he was formally asked whether he acknowledged them, his legal adviser, Jerome Schurpf of Sankt Gallen, insisted that the titles be read. In view of the gravity of recantation, Luther now asked for time to think, a request which may have taken his enemies off guard. A day's respite was granted, and the following afternoon, in a larger hall, and before an even more crowded assembly, Luther reappeared. This time he could not be prevented from making a long speech. He distinguished between his writings: for the works of edification he need not and ought not to recant, for the violence of his polemic he would apologize, but for the rest he could not recant; and, as he went on to explain why, the demand was brusquely made for a plain, simple answer. This he now gave in words of unyielding defiance. He would recant if convinced of his error either by Scripture or by evident reason. Otherwise he could not go against his conscience, which was bound by the word of God. The evidence is tilted against the authenticity of the famous conclusion, "Here I stand. I can do no other," but it registers the authentic note of Luther's reply in a moment which captured the imagination of Europe. There was a moment of confusion with Eck and Luther shouting, and then the emperor cut short the proceedings. Luther strode through his thronging enemies to his friends, his arm raised in a gesture of relief and triumph.

There followed a diplomatic flurry. It was evident that Luther had powerful friends, and there was some sabre rattling from the knights, while the peasant emblem *Bundschuh* appeared in the streets. There is evidence to support Luther's boast that had he wished he would have started such a game that the emperor's life would not have been safe. Thomas Müntzer (*q.v.*) later asserted that had Luther recanted the angry knights would have killed him. At any rate, Luther was now given what he had long asked for in vain, something like a real hearing before reasonably impartial judges, while he was kindly handled by the archbishop of Trier. But he could not now make minor concessions, and the discussions broke down on the fallibility of councils. He was formally dismissed and departed under his safe-conduct.

Nonetheless, despite the spectacular moral triumph, his enemies achieved something important at this point when a rump diet passed the edict of Worms. It declared Luther to be an outlaw whose writings were proscribed. It was to overshadow him and fetter his movements all his days. It meant also that his prince must, for a time at least, walk delicately and could not publicly support his protégé. The result was the pretended kidnapping of Luther who was lodged secretly in the romantic castle of the Wartburg, near Eisenach.

In this eyrie among the trees Luther remained until March 1522. Known as "Junker Georg," he dressed as a layman, grew a beard and put on weight. The lack of exercise, the unwontedly rich diet, brought on physical distress, constipation and piles, while his mind, flung back on itself after months of crisis, knew intense reaction in a period of acute depression of the kind which Luther ranked high among temptations (*Anfechtungen*). But he was far from idle. He finished a beautiful exposition of the *Magnificat* and prepared an edition of sermons on the Epistles and Gospels at Mass, *Enarrationes epistolarum et evangeliorum, quas postillat vocant*, which he thought was perhaps his best writing. Although away from books, he wrote his ablest controversial piece, *Rationes*

Latomianae confutatio, with its luminous exposition of justification. Most important of all, he began to translate the New Testament from the original Greek into German. He did not believe that such work should be left to one mind, and soon enlisted his colleagues, notably Melanchthon, in the enterprise. But Luther's was the controlling genius, and the resulting New Testament (published in Sept. 1522) and the Old Testament, translated from the Hebrew, which followed later (1534), was a monumental work, which had deep and lasting influence on the language, life and religion of the German people (see also GERMAN LITERATURE: *The Reformation*; BIBLE, TRANSLATIONS OF). He had now to deal with some practical implications of his revolt, for private Masses, celibacy of clergy, religious vows were no theoretic questions but were themselves entangled in a network of legal, financial and liturgical affairs. He wrote about these things forthrightly, and Spalatin tried in vain to hold up their publication. For in Wittenberg there were growing difficulties, and the prince, the university and the cathedral chapter were all, for various reasons, anxious to go slowly.

Commotion in Wittenberg, 1521-22.—There was a lively section of town and gown, however, that was determined to force the pace, and there were violent scenes in the streets and churches early in Oct. 1521. Yet Luther on a secret visit to his friends early in December was not alarmed, and it was his influence which led the Augustinians to decide, in the new year, that those of them who wished might return to the world. Two radical leaders now appeared, the incorrigible troublemaker Karlstadt and an ebullient spellbinder from the Augustinians, Gabriel Zwilling. When Karlstadt announced his betrothal to a girl of 16, and at Christmas administered communion in both kinds, dressed as a layman, attacked images in a violent tract and in innumerable theses denounced vows, Masses and demanded a vernacular liturgy, it was evident that here was a program which in timing and method differed from Luther's. Moreover its appeal to Scripture was legalistic and made matters of necessity things which for Luther lay within the option of Christian liberty. In the new year, the town council issued a notable and pioneering ordinance regulating religion, public morals and poor relief, a document which owes much to Luther's teaching and perhaps something to the initiative of Karlstadt. At the end of 1521 confusion was increased by the arrival of the so-called "Zwickau prophets," radicals on the run, who spoke impressively of revelations given them through dreams and visions. A flustered and outmaneuvered Melanchthon wrote urgently for advice to Luther, who sent wise and calm counsel.

In the next months the situation worsened and in March 1522 Luther returned to Wittenberg, explaining the reason for his disobedience to instructions in a justly famous letter to his prince. Then, deliberately habited as an Augustinian monk once more, he took charge of his town pulpit and in a powerful series of sermons redressed the balance of reform. In these important utterances, the difference between Luther's conservatism and the radical pattern of reform is made plain. Luther deplored the use of violence, for the word of God must be the agent of reform. The real idols are in the hearts of men and if their hearts are changed the images on church walls must fall into disuse. Moreover the pace of reform must take into account the unconverted, weaker brethren. From this time onward Luther fought a war on two fronts, against the Catholics and against those whom he lumped together as *Schwärmer* (fanatics). One result of the Wittenberg crisis was to slow down the practical reforms, and though Luther introduced a reformed rite (*Formula missae et communionis*, 1523) it was not until 1526 that he provided a vernacular liturgy (*Deutsche Messe*). Throughout Germany the evangelical movement continued to grow, and it was apparent that the edict of Worms would not be everywhere enforced. A diet at Nürnberg, 1522-23, refused to suppress the evangelical preachers and demanded a reforming, national council; though Catholic pressure was stronger in the following year, the diet again pressed for a council and would consent only to the enforcement of the edict "as far as possible."

Peasant War.—On his journeys to and from Worms Luther had been dismayed by the evident social and political unrest. In

the next months he wrote open letters, warning the rulers of Saxony and the councils of cities such as Strasbourg of the danger that the new radical teaching would provoke revolution. In 1523 he made his own views of secular government plain in the important treatise *Von weltlicher Obrigkeit* ("Of Earthly Government"), in which he firmly asserted the duty of a Christian prince and the place of secular government within God's ordinances for mankind; he distinguished between the two realms of spiritual and of temporal government, through which the one rule of God is administered, and stressed the duty of civil obedience and the sinfulness of rebellion against lawful authority.

In Saxony the radical teachers posed a problem for their untheological rulers. In Orlamünde Karlstadt had converted the community to his own brand of mystical quietism, drawing heavily on Tauler and on the *Theologia Germanica*, as well as on Augustine. Luther made a preaching tour of the area at the request of his prince, and was greeted with hostility and ridicule. Luther himself denounced social evils such as usury, but in Eisenach the fiery preacher Jakob Strauss conducted a violent campaign against usury and tithes. Most formidable of all, in the little town of Allstedt Thomas Müntzer, an unruly genius, combined his own ingenious liturgical reforms with a program of holy war. Himself a former "Martinian," he not only shared Karlstadt's enthusiasm for the mystics but added an explosive element (perhaps influenced by Hussite teaching) which gave point to Luther's worst fears. Luther's warnings and events themselves forced the rulers to take action, and in the summer of 1524 Müntzer fled and Karlstadt was exiled. Karlstadt wrote a series of tracts against his former comrades, denouncing, among other things, the corporeal presence in the Eucharist. Luther replied in a devastating and profound treatise, *Wider die himmlischen Propheten, von den Bildern und Sakrament* ("Against the Heavenly Prophets in the Matter of Images and Sacraments").

In the summer of 1524 the peasants' revolt had broken out in the Black Forest area. Their program was variously motivated. Their demands were for concrete medieval liberties connected with the game and forest laws or with tithes. Some of them drew on Catholic teaching, others on the theology of Zwingli and of Luther. The latter had set an example of successful defiance of authority and had been no respecter of dignities, such as the pope and Henry VIII of England. His teachings about Christian liberty and a priesthood in which all believers shared were plainer than his subtle distinctions between two kingdoms. Thus, both where he was understood and where he was misunderstood, his influence has to be taken into account. Some of the moderate peasants included Luther among possible arbitrators. He himself published in May 1525 the *Ermahnung zum Frieden*, an analysis of the "12 articles" of the Swabian peasants, sympathizing with just grievances, criticizing the princes, but repudiating the notion of a so-called "Christian" rebellion: "My dear friends, Christians are not so numerous that they can get together in a mob."

In the spring of 1525 the Thuringian peasants rose, with Thomas Müntzer among their leaders, and at first seemed likely to carry all before them. Faced with imminent political chaos, Luther wrote his brutal, virulent broadsheet, *Wider die räuberischen und mörderischen Rotten der Bauern* ("Against the Murdering, Thieving Hordes of Peasants"). The writing was less violent than Müntzer's hysterical manifestoes, but it was bad enough. It appeared, however, as an appendix to his moderate tract about the "12 articles." Moreover, words written at the height of the peasant success read very differently after the collapse at the battle of Frankenhausen, May 15, 1525, and in the bloody reprisal which followed. It was typical of Luther that he refused to climb down, to regain lost popularity, and neither thereafter nor at any time can he be accused of subservience to rulers. As he had refused to become the tool of the knights, in the time of Franz von Sickingen's desperate rising in 1522, so he had never "taken up" the peasant cause. But he confirmed many peasants in their preference for the radical ideology, which was soon to find more peaceful coherence in the Anabaptist movement.

Watershed Year, 1525.—In other ways, too, 1525 was a watershed in Luther's career. At the height of the peasant war in

June 1525, "to spite the devil" he had married Katherine von Bora, a former nun. He certainly needed looking after, and she proved an admirable wife and a good businesswoman. His home meant a great deal to him, and was an emblem for him of Christian vocation, so that he included domestic life among the three hierarchies of Christian existence in this world, the other two being political and church life. In the same year there came his open break with Erasmus. The differences between the two men had long been apparent, and Erasmus found in Luther the type of violent, dogmatic mendicant theologian he had always detested, while he liked what he saw of the Reformation less and less. Nonetheless, both men had a common band of admirers and friends, and entered the arena with reluctance. Erasmus, in his *De libero arbitrio* (1524), attacked Luther's doctrine of the enslaved will and provoked the resounding reply of Luther's *De servo arbitrio* (1525), a one-sided, violent treatise which nevertheless includes profundities still fruitfully debated. In that year, too, Frederick the Wise died. The two men met but once, but Luther owed much to this prince. The new ruler, the elector John, and his successor John Frederick, were Luther's devout supporters, and with other princes, notably Philip, landgrave of Hesse, and Albert of Brandenburg, formed a coherent group in the imperial diet.

The hostility of Charles V to the Reformers and his devotion to the Catholic faith never altered, but he had to take account of political exigencies, his quarrels with the pope and with the king of France and the need for support against the Turks. At the diet of Speyer in 1526 the edict of Worms was suspended, pending a national council; in the interval it was ruled that each prince must behave as he could answer to God and to the emperor. As a result, it was possible to plan the reorganization of the Saxon church, and a visitation was carried out by jurists and theologians, 1527-28. Some have seen a tension between Melancthon's *Instruktion für die Visitatoren* (1527) and Luther's comments, which may reveal his distrust of secular intervention in spiritual affairs; and though he thoroughly approved of the development of the evangelical *Landeskirchen*, there were to be aspects of Lutheranism which blurred rather than reflected Luther's theological distinctions. At the second diet of Speyer in 1529 renewed Catholic pressure led to the reversal of earlier concessions, drawing from the evangelical princes, and from a number of cities, a protest which won them, for the first time, the name "Protestant."

Eucharistic Controversy.—The difference about the Eucharist broke the common evangelical front. While all the Reformers repudiated the sacrifice of the Mass, they were deeply divided about the nature of the divine presence. Luther, with simple Biblicism, insisted that Christ's words "This is my body" must be literally interpreted, since allegory is not to be used in interpreting Scripture unless the context plainly requires it. Karlstadt's fanciful argument (that the word "this" referred not to bread and wine but the Lord's physical body) was soon dropped. But Zwingli won many to his view that "is" must be taken as "means," while his learned friend John Oecolampadius (*q.v.*) brought patristic support for a spiritual presence and stressed a phrase of Tertullian that "body" meant "sign of the body." Thus the initial debate was about exegesis, about the words of institution, though the scriptural argument moved to the relevance or irrelevance of the Gospel of John (*e.g.*, "he who eats my flesh and drinks my blood has eternal life," John vi, 54).

The debate turned to the intricate matter of Christology. Zwingli insisted on the distinction between the two natures of Christ, and that since to be in one place is the property of a human body, Christ's human body was not here but in heaven. Luther stressed the indivisible unity of the one person of Jesus Christ, the mediator. Without going into a metaphysical doctrine of "ubiquity" (which was developed by his disciple Johann Brenz and other Lutherans) he asserted that Christ is present where he wills to be, and that we are not to think of him in heaven "like a stork in a nest." Martin Bucer and the Strasbourg theologians echoed the more positive stresses of the Swiss, and Bucer used the realist language of the Fathers to support a true, spiritual presence. Luther's treatise *Dass diese Wort Christi "Dass ist mein Leib" noch fest stehen wider die Schwarmgeister* ("That these

words of Christ 'This is my Body' still stand firm against the fanatics," 1527) showed that in three years of controversy he had not budged. Zwingli's Latin tract *Amica exegesis* ("A Friendly Exegesis," 1527) was far less amicable than the title suggests and brought a great outburst from Luther, the impressive *Vom Abendmahl Christi, Bekenntnis* ("Confession About the Lord's Supper," 1528). This convinced Bucer that he had misunderstood Luther, who did not mean a local, confined presence, and from now on he intensified his awkward, well-intended attempts to make peace.

The political advantages of a common front were obvious, not least to the vulnerable Zwingli and Philip, landgrave of Hesse, and the prince invited theologians of both sides to a private colloquy at Marburg in Oct. 1529 (*see* MARBURG, COLLOQUY *or*). After three days' debate there was no agreement about the Eucharist, though it cleared the air of many misunderstandings. But if the conference failed there were agreements on other issues and these might have been fruitful had not the coming imperial diet caused the Wittenberg theologians to draw away from the Swiss. As an outlaw Luther could not attend this fateful diet of Augsburg, and had to fidget in the castle of Coburg, leaving the care of the gospel to Melancthon, who did very well and produced in the Augsburg Confession (1530) one of the great documents of the Reformation, as well as a normative confession of Lutheranism (*see* AUGSBURG CONFESSION; CONFESSIONS OF FAITH, PROTESTANT).

Luther used his influence to stiffen the elector against compromise, though from this time onward he could not refuse his consent to political Protestantism as it took a more and more military shape in the League of Schmalkalden (*q.v.*) in preparation for armed resistance to Catholic aggression. Again the political situation changed swiftly, however, and, confronted with the Turkish invasion, the emperor agreed to a truce with the Protestants in the religious peace of Nürnberg (1532). This was a valuable breathing space, and its effects are evident in Luther's writings in the next years. Now Luther left more and more matters to the action of Melancthon.

Growth of Lutheranism, 1530-46.—Luther acquiesced in the eucharistic agreement which the triumphant Bucer brought off with Melancthon in 1536 (the Wittenberg concord), though Bucer was unable to widen the agreement and bring in the Swiss. When an English embassy came from Henry VIII to discuss joining the Schmalkaldic league, it was Melancthon who drew up the theological agenda (the Wittenberg articles, 1535) with an ambiguous statement of justification of which Luther wrote "this agrees well with our teaching." But he would not follow Melancthon when he thought he wrote too irenically about the papacy, and as the papal council loomed near he penned his own uncompromising Schmalkaldic articles, a noble document (1537).

Melancthon's great work in the field of education was to earn him the name "preceptor of Germany," but Luther too was important in this matter. His open letter to the councilors of Germany about the need for schools, *An die Rathherren aller Städte deutschen Lands* (1524), and his published sermon *Dass man Kinder zur Schulen halten solle* ("On Keeping Children at School," 1530) show how wise and forward looking was his concern for education. He himself composed two important catechetical documents, the lovely classic, *Der kleine Katechismus* ("Small Catechism") and *Der grosse Katechismus* ("Larger Catechism," 1529) for teachers and pastors (*see* CATECHISM).

In Wittenberg Luther had a group of able colleagues: Justus Jonas, Johann Bugenhagen, Feliks Krzyzak (Cruciger). In scores of cities his disciples and friends spread the evangelical teaching which in these years formed the Lutheran pattern of church life. In the north of Germany and in Denmark it owed much to Bugenhagen. Luther, though not pre-eminent as a liturgist, provided orders of worship from which numerous other *Kirchenordnungen* were derived. The influence of Luther's writings was everywhere felt in the western Christian world. It was in Scandinavia that the Lutheran Church struck its deepest roots and won its most complete ascendancy, but it also had deep influence in Austrian and Hungarian lands. Luther realized the importance of hymns and encouraged his friends to write them. He wrote a score of fine

hymns, four of which appeared in the first Protestant hymnbook in 1524. The famous *Ein feste Burg ist unser Gott* ("A Safe Stronghold Our God is Still" or "A Mighty Fortress Is Our God") became almost an event in European history (see HYMN). In the last decade of his life Calvin was the rising portent in Switzerland, though Luther's personal contact with him was slight. He continued to attack bitterly the *Schwärmer*, who now included besides the Anabaptists a number of radicals such as Sebastian Franck and Kaspar von Schwenckfeld. Although he maintained to the end his view that error can be conquered only by the Word, he came to accept the punishment of the Anabaptists.

In 1540 Bucer and Melancthon took the initiative in conniving at the deplorable bigamy of Philip of Hesse, but Luther was involved and had he willed could have stopped it (see PHILIP [the Magnanimous]). It would have been easy for Philip to remedy his incorrigible incontinence by taking a mistress, but this he refused to do, though his guilty conscience kept him from the sacrament. The desperate device, as a lesser of evils, was to grant him a secret dispensation to take a second wife. When the affair became public Luther angrily threatened to write exposing the whole story. He himself was so far from lowering moral standards that in the next years he threatened to leave Wittenberg, since the public morals were a shame on a city which had known the evangelical teaching so long. After a serious illness in 1537 he was an almost chronic invalid, prematurely aged, seldom free from discomfort, often in pain, and he brought his teaching career to an end with the fine lectures on Genesis. In the last decade of his life he had to witness the recovery of the papacy, which he thought to have been mortally wounded, in the preparations for the Council of Trent, and the growing menace of Catholic military might. His last outstanding controversial treatise was *Von den Konziliis und Kirchen* ("Of Councils and Churches," 1539) though there are fine insights in the polemical *Wider Hans Worst* (1541). Among his last writings, against the Anabaptists, the Jews, the "Papacy at Rome, founded by the Devil" the most violent is the last, coarse, angry, but still defiant.

Early in 1546 Luther was asked to go to Eisleben, to mediate in a quarrel between two arrogant young princes, Counts Albrecht and Gebhard of Mansfeld (see MANSFELD). He was old and ill, but they were his *Obrigkeit* to whom he owed obedience and he set off in the snowy winter, leaving his wife stiff with anxiety. His letters to her teased her, comforted her and spoke at last of a mission successfully accomplished. But he had overtaxed his strength and in a few hours the chill of death came upon him. He died in Eisleben, the town where he was born, on Feb. 18, 1546, and his body was interred in the Church of All Saints, Wittenberg. The great funeral orations by Bugenhagen and Melancthon, who knew him so well, are not to be dismissed as simply panegyric. They witness that his intimates regarded him as a really great man, one standing within the historic succession of prophets and doctors of the church, through whose life and witness the Word of God had gone forth, conquering and to conquer.

Luther as Theologian.—Luther was no systematizer, like Melancthon or Calvin, though the dissensions among Lutheran theologians after his death, each appealing to one aspect of his thought, testify to the width, coherence and delicate balance of Luther's own teaching. The basis of his theology was Holy Scripture; and though the differences between his own and Augustine's thought are important, Augustine must stand next to the Bible among the influences upon his mind. The doctrines of salvation are of prime importance for him, and here the two great, many-sided complex conceptions of the Word and of faith are important. His often subtle doctrine about civil obedience was not always understood by his later followers, and nontheological factors in German history perpetuated and even perverted this misunderstanding. His doctrine of Christian vocation in this world, and the importance of human life in the world, became part of the general Protestant and Puritan inheritance. In other matters—in the room allowed for Christian liberty, in his conception of the part played by law in Christian life and in his insistence on the Real Presence in the Eucharist—his theology differs from the patterns which emerged in the Reformed (Presbyterian) churches, in Puri-

tanism and in the sects such as the Anabaptists. For portraits of Luther see articles GERMAN LITERATURE and REFORMATION.

See also REFORMATION; GERMANY: History; LUTHERANISM; and references under "Luther, Martin" in the Index.

BIBLIOGRAPHY.—This highly selective list can be supplemented by the comprehensive book list published annually in the *Luther-Jahrbuch*, ed. by Franz Lau; by the publications of the International Congress for Luther Research; and by the monthly literature survey in English and German published by the Lutheran World federation.

Editions and Translations: The Weimar edition by J. C. F. Knaake et al. (1883–) is the indispensable tool for serious Luther studies. Of older collections, that of Erlangen, ed. by J. G. Plochmann and J. K. Irmischer (1826–57) and by J. G. Walch (1740–50; rev. 1881–1910), are useful, that by Walch containing also rare tracts by Karlstadt and others. There is a key to these editions in K. Aland, *Hilfsbuch zum Luther-Studium* (1956). The most useful short edition is by O. Clemen (1950). The Munich edition of the German works by H. H. Borchardt and G. Merz (1913–25; 1951–53) has good notes and introductions. The American edition of Luther's works in Eng. trans., ed. by J. Pelikan and H. T. Lehmann (1955–), supersedes the Philadelphia edition, 6 vol. (1915–32). See also Luther's primary works in Eng. trans., ed. by H. Wace and C. A. Büchheim (1896); B. L. Woolf, *Reformation Writings of Martin Luther*, 2 vol. (1952); T. G. Tappert, *Letters of Spiritual Counsel*, Eng. trans. (1955); P. S. Watson (ed.), *Commentary on St. Paul's Epistle to the Galatians*, Eng. trans. (1953); J. I. Packer and O. R. Johnson, *On the Bondage of the Will*, Eng. trans. (1957).

Biographies: R. Bainton, *Here I Stand* (1951), is a scholarly and popular work; E. G. Schwiebert, *Luther and His Times* (1950); J. Mackinnon, *Luther and the Reformation*, 4 vol. (1925–30); R. H. Fife, *The Revolt of Martin Luther* (1957); H. Boehmer, *Martin Luther: Road to Reformation* (1957); E. G. Rupp, *Luther's Progress to the Diet of Worms* (1951); O. Scheel, *Martin Luther*, 2 vol. (1916–30); P. Smith, *Life and Letters of Martin Luther* (1911–14); G. Ritter, *Luther, Gestalt und Tat* (1950), the best short sketch; H. Strohl, *Luther, sa vie et sa pensée* (1953); G. Miegge, *Lutero*, vol. 1, (1946); W. J. Koorman, *Maarten Luther* (1948), Eng. trans., *By Faith Alone* (1955); F. Law, *Luther* (1964); V. Green, *Luther* (1964).

Studies: The variety of histories of Luther is symptomatic of the complexity of Luther studies. They include A. Herte, *Das katholische Lutherbild*, 3 vol. (1943); E. W. Zeeden, *Martin Luther und die Reformation*, 2 vol. (1950), Eng. trans. *The Legacy of Luther* vol. 1 (1954); H. Stephan, *Luther in den Wandlungen seiner Kirche* (1951); H. Bornkamm, *Luther im Spiegel der deutschen Geistesgeschichte* (1955); E. M. Carlson, *The Reinterpretation of Luther* (1948). See also B. J. Kidd, (ed.), *Documents Illustrative of the Continental Reformation* (1911); O. Scheel, *Dokumente zu Luthers Entwicklung* (1929); H. Strohl, *Substance de l'évangile selon Luther* (1934); P. J. S. Reiter, *Martin Luthers Umwelt, Charakter und Psychose*, 2 vol. (1937–41); E. H. Erikson, *Young Man Luther* (1958); P. S. Watson, *Let God be God!* (1947); E. G. Rupp, *The Righteousness of God* (1953); K. Holl, *Gesammelte Aufsätze*, 3 vol. (1927–28); E. Hirsch, *Lutherstudien*, 2 vol. (1954); R. Herrmann, *Gesammelte Studien zur Theologie Luthers* (1960); H. Strohl, *L'Épanouissement de la pensée de Luther* (1924); V. Vajta, *Die Theologie des Gottesdienstes bei Luther* (1952), Eng. trans., *Luther on Worship* (1958); W. von Loewenich, *Luthers Theologia Crucis* (1954); R. Prenter, *Spiritus creator* (1946); G. Törnqvall, *Andligt och världligt regemente hos Luther* (1940), Ger. trans., *Geistliches und weltliches Regiment bei Luther* (1947); G. Wengren, *The Christian's Calling, Luther on Vocation* (1957); W. Link, *Das Ringen Luthers um die Freiheit der Theologie* (1955); J. Heckel, *Lex charitatis* (1953); E. Bizer, *Fides ex auditu* (1958); R. Prenter, *Der barmherzige Richter* (1961). Fictional studies to be commended are the Victorian novels by E. Charles, *Chronicles of the Schönborg-Cotta Family* (1892), and the play by John Osborne, *Luther* (1962). (E. G. Ru.)

LUTHERANISM, the general title given to the branch of the Western Christian church that adopted the religious principles of Martin Luther (q.v.), as opposed to those of the Roman Catholic Church and of the followers of John Calvin, the Anglican communion and the sectaries of the times of the Reformation. Lutheran churches often term themselves Evangelical as distinct from Reformed, but these uses are not always strictly applied.

Lutheran doctrinal statements are usually said to include nine separate formulations which together form the Book of Concord (see CONCORD, BOOK OF). Three belong to the early Christian church—the Apostles' Creed, the Nicene Creed in its western form and the so-called Athanasian Creed (see CREED). Six derive from the 16th-century Reformation—the Augsburg Confession, the Apology for the Augsburg Confession, the Schmalkald Articles, Luther's two Catechisms and the Formula of Concord (see AUGSBURG CONFESSION; CATECHISM; CONFESSIONS OF FAITH, PROTESTANT). Only the three early creeds and the Augsburg Confession are recognized by all Lutherans. Luther's Catechisms have met almost universal acceptance, but many Lutheran churches re-

jected the Formula of Concord because of its strict and detailed doctrinal statements. The Augsburg Confession and Luther's Small Catechism may properly be said to define Lutheranism inclusively in its doctrinal aspect, though Lutherans may be divided on many issues raised since the Augsburg Confession of 1530.

Lutheranism acknowledges no world headquarters, but the vast majority of the world's Lutherans co-operate in the Lutheran World federation, which has offices in Geneva, Switz. Statistics of the bodies which make up Lutheranism are difficult to gather, in part because many Lutherans live behind the "iron curtain" and in various underground situations. Estimates at the end of the 1950s placed the total number of Lutherans in the world at 70,000,000 to 80,000,000; over 50,000,000 of these were represented in the federation. In the United States, Lutheranism makes up the third largest family of Protestant denominations, with 8,000,000 baptized members, over 5,500,000 of whom are confirmed.

The oldest and the largest of non-Roman Catholic, non-Orthodox families of Christians, Lutheranism is represented in most areas of the world. But its particular geographical orientation has been in northern and western Europe and in younger countries settled by Germans and Scandinavians. It has been represented with less strength in Switzerland, the Lowlands and Scotland, where Reformed confessions predominated, and it has been a secondary influence in the British empire and the Commonwealth of Nations, where the Anglican communion has prevailed. Because of early and persistent efforts of continental missionary societies and later separate Lutheran denominations, Lutheranism has been significantly represented in the mission fields and in the formation of what were formerly called the younger churches.

HISTORY

Origins.—Lutheranism considers itself to be "catholic" in its affirmations about its own universality and its continuity with Christian expression in every time and place; it considers itself to be "protestant" in that its root experience involved a rejection of much of Western (or Roman Catholic) dogma and piety. The movement which gave Lutheranism its birth as a separate entity within Christendom originated with the German Augustinian monk Martin Luther. Lutheranism cannot be defined or understood without some reference to the personal experience and the biblical studies of Luther, which came to voice in 1517 in his theses for debate over indulgences and in his attack on the theology and sacramental practice of the late medieval church of the west. In 1521 Luther was excommunicated; his followers accepted the designation "Lutheran" in part against his will and in spite of the fact that it was filled, in many instances, with implications of derision and sectarianism. The Lutheran movement spread from the University of Wittenberg through much of Germany and into Scandinavia.

Germany.—So much of the formative experience of Lutheranism occurred in Germany that it is profitable to trace developments there. Luther died in 1546; after his death the more rigid Lutherans declared it to be their duty to preserve the status of religion in Germany as it had been established by Luther and to watch over the Christian teaching as it had been committed to their charge. Luther, however, had been greater as a preacher than as a systematic thinker; this made it difficult to determine what the measure of Lutheran thinking was, and controversies resulted among the Lutheran theologians of the 16th century.

1. The Antinomian controversy (*see* ANTINOMIANISM), the earliest (1537–60), arose from differences about the precise meaning of the word law in Luther's distinction between law and gospel. Luther had limited the meaning of the word to imply a definite command accompanied by threats, which counts on terror to produce obedience. He declared that the Christian was not under the dominion of the law in this sense of the word, and that believers enter the Christian life only when they transcend a rule of life which counts on selfish motives for obedience. But law may also mean ethical rule, and the Antinomians so understood it and interpreted Luther's declaration to mean that believers are not under the dominion of the moral law.

2. The Arminian controversy in the Reformed Church and the

Jansenist controversy in the Roman Catholic Church (*see* ARMINIANISM; JANSENISM) had their parallels in disputes among the Lutherans lasting from 1550 to 1580. In the end it was generally agreed that sin had not totally destroyed man's ethical nature, and that grace changed what was morally insensitive into what was morally sensitive, so that there could be a co-operation between God's grace and man's will ("synergism").

3. The controversy raised by Andreas Osiander (*q.v.*) was more important. Osiander felt that Luther had omitted to answer adequately an important practical question, how Christ's death on the cross could be brought into such connection with every individual believer as to be the ground of man's justification. It was answered that the principal effect of Christ's work on the cross was to change the attitude of God toward the whole human race, and that, in consequence, when men come into being and have faith, they can take advantage of the change of attitude effected by the past historical work of Christ. The Reformed Church, on the other hand, had its own distinctive doctrine of the atonement, with a strong emphasis on predestination.

4. The other controversies concerned mainly the doctrine of the sacrament of the Lord's Supper and Luther's view of the Real Presence, sometimes described as consubstantiation. This required a doctrine of ubiquity, or the omnipresence of the body of Christ extended in space, and therefore of its presence in the communion elements. Calvin had taught that the true way to regard substance was to think of its power (*vis*), and that the presence of a substance was the immediate application of its power. The presence of the body of Christ in the sacramental elements did not need a presence extended in space. Philipp Melancthon and many other Lutherans, leaning toward the theory of Calvin, claimed that Luther had approved of it before his death. Thereupon the more rigid Lutherans accused their brethren of crypto-Calvinism and began controversies which dealt with that charge and with a defense of the idea of ubiquity. The University of Jena was the headquarters of the stricter Lutherans, led by Matthias Flacius Illyricus; Wittenberg and Leipzig were the centres of the Philippists or followers of Melancthon (*see* also FLACIUS ILLYRICUS, MATTHIAS; MELANCTHON, PHILIPP). Conferences were called, but they served only to increase the differences. The Lutheran Church seemed in danger of falling to pieces. In the end, however, due mainly to the efforts of Augustus, elector of Saxony, the greater proportion adopted the Book of Concord (1580). The churches within Germany that refused the Book of Concord became for the most part Calvinistic or Reformed; as was the fashion among the Reformed churches, they published separate creeds, but almost all accepted the Heidelberg Catechism (*q.v.*).

The divided state of German Protestantism that resulted from these theological differences contributed in no small degree to the disasters of the Thirty Years' War, and various attempts were made to unite the two confessions. Conferences were held at Leipzig (1631), Thorn (1645) and Kassel (1661), but without success. At length the union of the two churches was effected by the force of the civil authorities—in Prussia (1817), in Nassau (1817), in Hesse (1823), in Anhalt-Dessau (1827) and elsewhere. These unions for the most part aimed not at incorporating the two churches in doctrine and in worship but at bringing churches or congregations professing different confessions under one government and discipline. Each congregation was permitted to use at pleasure the Augsburg Confession or the Heidelberg Catechism.

In Prussia the enforced union was combined with the publication of a new liturgy intended for use in all churches, and this led to secessions from the state church. The seceders were at first treated with great harshness, but through the years won their way to toleration; they were eventually permitted to form the Lutheran Free or Old Lutheran churches of Germany.

After World War I a strong effort was made to separate church and state in Germany. The churches were guaranteed diminishing state support, with the ultimate purpose of divorcing them entirely from the state, or *Länder*, governments. The acute economic depression of 1922–24 affected most disastrously those elements of the laity from which the greatest measure of church support was

to be expected, and it subjected the clergy to severe privations. When Nazi rule imposed its discipline on the German Lutheran churches it was met with acquiescence and even support by some who made up the so-called German Christian movement, actually sponsored by the Nazi government. But leading Lutherans also took a prominent part in the Confessing Church movement, which resisted Nazi efforts to use Christianity for its own ends (see GERMAN CONFESSING CHURCH). After the defeat of Germany in 1945 the Protestant churches were particularly affected by the partition of Germany. The area controlled by the U.S.S.R. was the most strongly Protestant part of the country, and of the 11,000,000 and more refugees from the east in the Federal Republic of Germany a decade after World War II the great bulk was Protestant, for the most part Lutheran.

Outside Germany.—From the first days of the Reformation Lutheranism spread quickly from Germany to other countries, but its course of development elsewhere was different. The most significant converts to Lutheranism were the people of the Scandinavian countries. Change began to occur there in a time of rising nationalism under Christian III (*q.v.*), who established in Denmark codes limiting corrupt practices in the church and ecclesiastical ownership of property, and permitting the clergy to marry. But as political situations changed, so did the fortunes of Lutheranism, and its successes were not fully apparent until a generation of the influence of Lutheran scholars, particularly from Wittenberg, had been felt. Under Gustavus I (*q.v.*) Vasa, modern Sweden and Lutheran Sweden developed; later Roman Catholic kings could not bring about a reversion to Roman Catholicism. Iceland and Norway followed, though at first the imposition of Reformed Christianity was not popular. Under the influence of Michael Agricola, Finland also chose Lutheranism.

In these northern countries the Lutheran Church was established by law, and to this day the vast majority of the population is at least nominally Lutheran. These national churches have retained the traditional episcopal system of government from the medieval church, but only Sweden has kept unbroken the succession of episcopal consecration. Particularly in the 20th century the Scandinavian churches have been theological leaders in world Lutheranism.

Lutheranism had early spread also to eastern Europe, though it never became dominant there. Hungary was attracted in part because of German cultural influence in the 16th century. Several Czechoslovakian religious parties were affected by Lutheranism. The greatest extent of Lutheran influence in eastern Europe, however, could be seen in the Baltic states, where independent Lutheran churches were formed when political independence came after World War I. But the organization of the churches in Latvia, Estonia and Lithuania was disrupted by successive German and Soviet occupations during and after World War II, after which many of their members became refugees from Communist rule and established Baltic churches "in exile." While Estonian, Lithuanian and Latvian churches are the only Lutheran churches recognized in the U.S.S.R., numbers of Lutherans were permitted to organize officially in Russia in 1924; however, Communist suppression greatly reduced their numbers. Czechoslovakian and Hungarian churches are members of the Lutheran World federation. Some Lutherans are found in almost every nation, and significant numbers appear in the parts of the world—e.g., Brazil, India and Indonesia—where European and American mission work has been vigorous.

United States.—Lutherans were among the earliest American colonists who settled in New Netherland and New Sweden (on the Delaware river), and they were followed by German colonists who settled especially in the present Middle Atlantic states, the Shenandoah valley, Georgia and Nova Scotia. Because of some geographical and much linguistic isolation and because the majority of American Protestantism was at first of Reformed background, Lutheranism did not play a major role in helping shape the early political and religious complex of the nation. Because of its minority status and its relative strength in the middle colonies, its tendency in America, contrary to its generally Erastian relationships in Europe, was to favour separation of church and

state against the establishments of the late colonial and early national periods.

The geographical spread of Lutheranism was extended by migrations to the western frontier and by the large immigrations during the 19th and early 20th centuries of Germans, Norwegians, Swedes, Danes and Finns. Many of these immigrants settled in the middle west, and from there later pushed on to the far west. Consequently Lutherans came to be distributed among all the states of the United States and the provinces of Canada. Their strongest concentrations are in the New York-Pennsylvania-Maryland-Virginia arc and in the upper midwest.

Since immigrants brought with them from Europe a variety of languages and customs, they organized in congregations and later synods according to their national origins; originally the names of synods tended to reflect their members' European provenance. It was the prolongation of linguistic and ethnic barriers that prevented Lutheran union until well into the 20th century, when the barriers broke down and advance into intra-Lutheran ecumenical relations became rapid. Traditionally, Lutheran growth from insignificance in the colonial period to third place in American Protestantism was accounted for in terms of immigration and propagation. However, as geographical and linguistic isolation disintegrated, most Lutheran bodies undertook expansive and energetic missionary activities which help to account for a rapid growth rate. In the American environment all Lutherans in time adopted the English language—more quickly in the east than in the west, where the effects of immigration were felt longer—and this was accompanied not only by the discarding of national references in synodical ties but also by closer association on the part of once-separated people and by an inclination of some Lutheran expression to be hyper-American.

During the period of rapid Lutheran growth in America in the mid-19th century, when immigration from central Europe increased, the efforts of such men as Samuel Simon Schmucker of Gettysburg seminary to write Lutheranism into the common fabric of American evangelicalism were countered by a vigorous and conservative confessionalism, typified by Charles Philip Krauth in the east and Carl Ferdinand Wilhelm Walther (*q.v.*) in the midwest. The resurgence of confessionalism and the variety of national origins inhibited the attempt to "Americanize" and unite Lutheranism. However, even in this period efforts were made toward reunion. These took, unfortunately, four different forms: (1) the General Synod of 1820, weakened now by the advance of confessionalism; (2) the United Synod in the South, a product of the Civil War; (3) the General Council (1867), itself conservative in its protest; and (4) the intransigent Synodical Conference (1872) led by the Missouri Synod.

The most significant turn toward union of Lutheran bodies came in the formation in 1918 of the United Lutheran Church in America out of dozens of once-autonomous synods; this marked a trend that still continues. Co-operative efforts were carried on not only along lines of merger but also by councils and federations, among them the National Lutheran council and the American expressions of the Lutheran World federation. All the larger bodies except the Missouri Synod have united in these, and Missouri, which undertook some co-operative activities with them, has grown closer to the councils and federations. The most significant trend in American Lutheranism after 1918, for better or for worse, was its tendency to let itself be seen as a typical or mainstream American denomination instead of as a stream parallel to Methodism, Episcopalianism, etc.

There are about 8,000,000 baptized Lutherans in the United States. As new mergers are effected, American Lutheranism is taking on more and more a tripartite jurisdictional arrangement, with three approximately equal-sized groups: (1) American Lutheran Church, formed in 1961 by amalgamation of American Lutheran Church, Evangelical Lutheran Church, United Evangelical Lutheran Church and Lutheran Free Church; (2) Lutheran Church in America, formed in 1962 and made up largely of United Lutheran Church in America, Augustana Evangelical Lutheran Church, Finnish Evangelical Lutheran Church (Suomi Synod), and American Evangelical Lutheran Church; and (3) Evangelical

Lutheran Synodical Conference of North America (Synodical Conference), formed in 1872 and including the Lutheran Church—Missouri Synod and the Synod of Evangelical Lutheran Churches; formerly the Wisconsin Evangelical Lutheran Synod and the Evangelical Lutheran Synod were included in the Synodical Conference but later became independent.

Five or six small independent groups with a total membership of fewer than 50,000 adults complete the Lutheran picture in the United States.

International.—Internationally, Lutherans became most aware of each other after World War II, when physical and spiritual needs were most dramatic. No other Protestant family of churches had been in geographical situations where so much suffering occurred. Among the most fortunate in avoiding the sufferings of war were the Americans, who were able to share their resources with displaced and exiled refugee Lutherans and with Christians rebuilding in western Europe. The main organ of this relief activity was the Lutheran World federation; among non-members of the federation, the Lutheran Church—Missouri Synod played a predominant role. All these bodies worked to establish new churches where none had existed or to strengthen existing churches, along with relief work. It was this form of activity, for example, that led to the formation of the Lutheran Church in Britain, where Lutherans had been largely unrepresented. Lutherans also have made major contributions to the World Council of Churches.

POLITY, WORSHIP AND DOCTRINE

Polity.—The church of the Augsburg Confession does not define itself in the language of polity or church government. Its unwillingness to do so has complicated ecumenical discussion with those churches that do. Concerned for good order in the church, it has not historically tied itself to a theological insistence on one specific form of order. It sees various forms of polity to be of the *bene esse*, but ordinarily none of them to be of the *esse* of the church. Minimally, Lutheran order consistently strives on the one hand against anarchy in church government; this is consistent with the denomination's general respect for authority in response to Pauline teaching in Rom. xiii. On the other hand, its order seeks to resist the authoritarianism which historic Lutheranism saw in Roman Catholicism.

The churches of Scandinavia, where the transition to Lutheranism was most easily effected, have kept the episcopal form of government, but only in Sweden has there been a stress on the continuity of orders from apostolic times in unbroken succession. The German churches for the most part have functioning bishops without insistence that their office belongs to the *esse* of the church. In American Lutheran polity, bodies are organized co-operatively into synods, but individual congregations retain a great measure of local autonomy.

The Lutheran churches, though they attacked the clericalism of the medieval church, refused to see ordination as a sacrament and insist on the priesthood of all believers, have always tended to regard the ministry of the Word and sacrament in high and special terms. No one was to engage in public ministry or to administer the sacraments (*nisi rite vocatus*) unless he was properly called (though propriety was not defined in detail). The tendency to elevate the ministry is due in large part to the Reformation's insistence that the preacher be a scholar, adept at exegesis and exposition of the sacred Scriptures. Thus while in theory an educated layman may possess all the charismatic powers a clergyman does, good order usually militates against thinking of him as technically equipped for the public ministry.

The prime ecclesiastical unit of American Lutherans (as for most of world Lutheranism) is the local congregation, the product of the original settlements or of aggressive home missionary activity. In the United States, because of the original rural dominance, Lutheran congregations on the average number fewer than 500 baptized and 300 confirmed members, usually organized under the pastoral care of one "called" minister and administered on conciliar and democratic lines. The congregation is seen to be a microcosm of the whole church, possessing all rights and privileges of the

whole Christian church (including, for example, the right to call their pastors and confirm their members); surrender of any of these rights for the sake of good order to ecclesiastical jurisdiction beyond the local level is voluntary. However, the complexity of a specialized and technical society has led American Lutherans more and more to organization and away from strong emphasis on congregationalism in most ecclesiastical functions. Local congregations usually preserve biblical terminology in relation to public office (pastor, elder, deacon, etc.); on the national level the language of democratic institutions (president, executive secretary, etc., instead of bishop, canon, etc.) predominates.

For church organization in countries where Lutheranism is the established church, see DENMARK; FINLAND; ICELAND; NORWAY; SWEDEN.

Missionary Activity.—While the early movement of Lutheranism was largely through the official conversion of states and nations from Roman Catholicism, later Lutheranism compensated for the general lack of missionary interest in the 16th and 17th centuries. During the half-century when the modern missionary movement was getting underway a number of Scandinavian and German missionary societies were initiated, usually at the behest of groups within the churches and not by the official bodies. This period of missionary societies' prevalence lasted from the 1790s into the middle half of the 19th century. In later years the official churches of Germany and the denominational boards in the United States churches took over much of the initiative from the voluntary societies, and Lutherans are represented in most of the Christian mission fields. They have worked with particular effectiveness in India, Indonesia (Sumatra) and in Tanganyika and other African regions.

Education.—Lutheranism was born in scholastic disputes, and since it emphasizes faith, the knowledge that accompanies faith, and the study of the Holy Scripture it has historically shown interest in the educational enterprise of the church. Martin Luther was instrumental in bringing about reforms in the education of German children; his Small Catechism illustrates his pedagogical interest. At many of the state-supported universities of Germany and the Scandinavian countries the theological faculties have been Lutheran.

In the western hemisphere much of the church's concern for education has continued. Some Lutheran groups, notably the Lutheran Church—Missouri Synod, have established parochial schools on the elementary and secondary level. In general the colleges that were founded under Lutheran auspices have remained under church control. Each branch of American Lutheranism has a number of theological seminaries, which insist on high intellectual standards for the ministry. In these educational ventures Lutheranism professes its first concern to be the development of students of the sacred Scriptures.

Deaconess Movement.—The modern employment of women for Christian service in the form of a diaconate received its major impetus from continental Lutheran sources. Theodor Fliedner (q.v.), beginning at Kaiserswerth, Ger., about 1833, encouraged young women to participate in orders devoted to acts of Christian mercy. In 1836 he established a "mother house" at Kaiserswerth that became the model for many successors. The deaconesses were consecrated for their activity, but took no vows as members of Roman Catholic orders do. Through the activity of Konrad Wilhelm Loehe at Neuendettelsau (1849) the work of deaconesses came to be known in America; in the middle of the 19th century chapter houses began to appear in the United States, and deaconess work continues to this day. Characteristically, deaconesses are involved in eleemosynary activity at hospitals, institutions or in parishes.

Publishing.—Lutheranism, because of its devotion to the interpretation of Scripture and its concern for doctrine, propagated itself from the first in no small measure through the printed page. Luther and his associates immediately seized on the new invention of printing to publicize their doctrines and wage verbal warfare against their enemies. Both continental and American branches of the church body have established publishing houses to supply Bibles, hymn and prayer books, doctrinal studies and, more re-

cently, practical aids to church life. Among the larger commercial ventures in the United States are Fortress (formerly Muhlenberg) Press, Augsburg Publishing House and Concordia Publishing House.

Worship.—Lutheran worship to the present time, despite local and temporal cultural accommodation, derives largely from principles enunciated by Martin Luther. His *Deutsche Messe* of 1526 was a common service which returned vernacular worship and enlarged congregational participation; his more formal and conservative *Formula missae et communionis* retained more of the medieval liturgy but was equally careful to purge what were seen to be unevangelical developments. Thus, unlike the radical Reformers, Lutheran participants did not conceive of themselves returning to New Testament primitivism but allowed for traditional and historical development. Luther's services were, with some marked exceptions, carry-overs from the medieval offices.

Luther himself described worship in dialogic terms, as a conversation between man and his Maker, and Lutheran architecture and liturgy seek to preserve this conception. Luther saw Word and sacrament as two poles of an ellipse, refusing to grant priority to one or another because he saw in them a perfect relation. His successors, when under Reformed influence, have emphasized the pulpit and the read or preached Word at the expense of baptism and the Lord's Supper. Others, of "high" church tendencies or under Roman or Anglican influence, in subsequent centuries have championed the sacraments, sometimes at the expense of the written and spoken Word. The eucharistic recovery and renaissance characteristic of all Christian churches in the 20th century has also been marked in Lutheranism, where emphasis on the sacraments has restored Luther's concrete conception of the work of the Holy Spirit with no accompanying loss of interest in preaching and expounding the Scriptures.

The chief changes effected by Luther and Lutherans as they assumed the order of the Mass are these: the service was in the vernacular; the sermon was no longer an optional but an organic element in the service; the sacrificial prayers of the canon of the Mass were removed; the singing of hymns became prominent. This last element came to characterize the Reformation movement, flowered in the form of the Lutheran chorale and reached its climax in the musical tradition typified in the work of J. S. Bach. Lutheran services are ordinarily formal but relatively simple. Lutheran architecture varies according to time and place, but pulpit and altar are always given prominent places. While Lutheranism does not insist on uniformity in worship, a degree of uniformity has developed because of the inner logic of the service as it is connected with Lutheran theology and because of the widespread acceptance of common hymnals and books of order. (See also *Liturgy: Protestant Liturgies*.)

Doctrine.—The Lutheran Church is characterized primarily by its doctrinal rigour and by its organization around loyalty to a central Christian teaching classically expressed as the doctrine of justification by faith (*justificatio sola fide*). As no aspect of Luther's theology can be understood without reference to the witness to God's forgiving activity in Jesus Christ, so the core of Lutheran theology, "the article upon which the church stands or falls," is justification, as expounded decisively in article iv of the Augsburg Confession:

We cannot obtain forgiveness of sin and righteousness before God by our own merits, works, or satisfactions; but we receive forgiveness of sin and become righteous before God by grace, for Christ's sake, through faith, when we believe that Christ suffered for us and that for his sake our sin is forgiven and righteousness and eternal life are given to us.

At the base of this belief is a serious view of man's distance from God as the result of his sin, which removes him as a total being from God's favour. He cannot please God or become righteous by his own achievements. Thus man's salvation, which is a loving God's central concern, depends entirely upon God's initiative in his reconciling activity in Jesus Christ.

Lutheran teaching was ranged against Roman Catholic ideas of man's righteousness as based at least in part on his own efforts or merits. According to Lutheran doctrine, man cannot even prepare himself to receive grace. All initiative remains with God, so

that he shall receive all honour and man shall have greater certitude. Man becomes part of this divine and sovereign saving activity by faith. While response in faith is the key to Christian living in Lutheran eyes, Lutheran theologians have always been careful to insist at this point also on the exclusiveness of divine grace in the operation of reconciliation. Faith is instilled, says article v of the Augsburg Confession, by the Holy Spirit when and where it pleases God, in the hearts of those who hear the gospel. The accent in such a view of faith's response is on *fiducia* or confidence, in distinction to the Roman stress on assent. The justified man, in Lutheran teaching, after the imputation of righteousness, remains a sinner (*simul justus et peccator*). The emphasis on divine initiative also separates Lutheran teaching from those Reformed confessions which retain elements of synergism, and in particular is distinct from Arminianism, with its great interest in man's striving and his co-operation. Thus within Protestantism, Lutheran theology is somewhat set apart by a relative understress on sanctification. This avoidance of preaching on man's co-operative part has led to certain elements of quietism and ethical disinterest in Lutheran orthodoxy, which has been countered repeatedly through Lutheran history by pietist movements (see *PIETISM*).

There are also resources within classic Lutheranism to prevent it from lapsing into ethical apathy and unconcern or into Antinomianism. A radical distinction between law and gospel lies at the heart of this resource. For Luther the mark of the theologian was his successful discrimination within the Word of God between law and gospel. The law always accuses, serving less as a guide than as an agent to drive man into the waiting arms of a forgiving God and Father. The gospel brings the good news of salvation and is the proper work of God (*opus proprium* as opposed to *opus alienum*, a distinction taken over from Is. xxviii, 21).

The rest of Lutheran teaching is largely a corollary or an outgrowth of its central teaching of justification. This teaching has brought Christology or soteriology to focus in all Lutheran theological discussion, a focus evident in the piety and preaching of Lutherans for four and one-half centuries. The ethical stress of the confession then becomes the belief that man can be a Christ to his neighbour, that faith becomes active in love. A righteousness based on the law, or good works based on legalistic motives are completely ruled out. Again, Lutherans have tended to lay greater stress on the doctrines of the atonement than on creation and incarnation, because it is in the atonement that God's initiative in human history is largely concentrated.

It is in the light of its Christology that Lutheran emphasis on the Real Presence of Christ in the Eucharist (article x of the Augsburg Confession) is seen. It would guard against over-materializing the Presence as it believes Roman Catholic views of transubstantiation (*q.v.*) do, and equally against over-spiritualizing, as in the case of Reformed teaching. Christ is present in a bodily way with the bread and wine of the Lord's Supper through a sacramental union. Yet the elements remain bread and wine and the communicant receives both. The body and blood are present "in, with and under" these elements. Lutheran theology agrees with the Catholic tradition that Christ is present in both his divine and human natures. This led to disputes with the Reformed, who argued against such a view with its implication that both Christ's divine and human natures are omnipresent. Insistence on the "hypostatic union" and thus on the Catholic witness to the fullness of the Person of Christ was behind Lutheran intransigence in its meetings with Reformed theologians in the unity efforts of the 16th century and remains as the hidden interest behind all sacramental discussion to this day.

The formal principle of Lutheran theology is its insistence that the canonical Scriptures are the only source and norm of Christian faith and practice. Most Lutherans hold to a very elevated view of scriptural authority; they see the Scriptures from within the church, finding the evangelical accent of their confessions to be the key to understanding the Bible, and the doctrine of justification by faith in its residence in Christology to be the note around which all scriptural witness is gathered.

Distinctiveness.—Since the Lutheran confessions try to stand in the ancient and catholic tradition it is difficult to find absolute distinctions between Lutheranism and its Christian alternatives. But relative distinctions there are. It is doctrinally more rigorous than most; its worship is serious, but it represents a *via media*; its political interest has been a fairly consistent witness to God's authority in setting up human authorities. For the most part Lutherans have taken an active part in the ecumenical movement, trying to find ways to accept other Christians as brothers in Christ without diluting Lutheran strength in the matters of God's initiative and man's response through faith in Jesus Christ.

(MA. E. M.)

LUTHULI, ALBERT JOHN (1898–), South African tribal chief who was awarded the Nobel peace prize for 1960, was born in Southern Rhodesia, the son of an African Christian missionary of Zulu stock, to whose family home at Groutville, Natal, he was taken while still a boy. After completing his education at Adams college, near Durban, he taught there for 15 years till 1935, when he was elected tribal chief of Groutville. He then did much to improve the economic position of African sugar farmers in Groutville and elsewhere. Just before World War II he was a delegate to an international missionary conference at Madras, India, and in 1948 he went to the United States to lecture about Christian missions in South Africa. Long interested in the political advancement of Africans, he finally joined the African National congress (A.N.C.) at the end of World War II. An advocate of nonviolent resistance to the South African government's policy of apartheid, he helped to organize a campaign of civil disobedience in 1952. For refusing to resign from the A.N.C., of which he was elected president (also in 1952), he was deprived of his chieftainship by the Native Affairs department. Arrested on a charge of high treason in 1956 but later released, he was in 1959 forbidden for five years to leave his home district; in 1960 the South African government banned the A.N.C. In announcing the award of the Nobel peace prize to Luthuli the prize committee cited his long fight against racial discrimination by nonviolent means. The South African government denounced the award but nevertheless granted Luthuli and his wife permission to travel to Oslo, Norway, to accept the prize in Dec. 1961. The following year Luthuli published his autobiography, *Let My People Go*.

LUTON, an industrial and market town, parliamentary and county borough (1876) of Bedfordshire, Eng., is 31 mi. N. of London by road. Pop. (1961) 131,505. The town lies on the source of the river Lea and has spread north and east over the surrounding Chiltern hills. George street, the main shopping centre, has the town hall (1936) at one end, and Park square, where there is a large technical college (1959), at the other. The principal parks are Stockwood (244 ac.) and Wardown (50 ac.), which adjoins a large open-air swimming pool. The parish church of St. Mary is mainly 15th century; special features are the unique canopied baptistery, and the Wenlock chapel, which contains the helmet and gloves worn by Sir John Wenlock at the battle of Tewkesbury (1471). Long famous for the manufacture of straw hats, particularly "boaters," Luton is now principally a light engineering town with two large motor vehicle works, one of which employs more than 25,000 people. Other manufactures include aircraft, ball bearings, precision instruments, refrigerators, vacuum cleaners and other electrical goods. The hat trade still prospers, though felt hats are now principally made. The modern municipal airport has charter and freight services.

The district was populated in prehistoric times and many discoveries have been made of settlements from the Old Stone Age

to the Iron Age. A large collection of artifacts is on view at the museum in Wardown park, which also specializes in the history of the straw plait and hat industry.

King John granted Luton to the notorious Falkes de Bréauté (see BRÉAUTÉ, FALKES DE), who established a castle there. Later lords of the manor lived at Luton Hoo, 2 mi. S.E., present site of the priceless Wernher collection of porcelains, enamels and other art treasures.

(F. M. GA.)

LUTSK, a town and administrative centre of Volyn oblast of the Ukrainian Soviet Socialist Republic, U.S.S.R., is 136 km. (84 mi.) N.E. of Lvov and stands on the Styr river, where it emerges from the Volyno-Podolsk upland into the Polesye lowland. Pop. (1959) 56,282. Lutsik is one of the oldest towns of Russia. First mentioned in documentary evidence in 1085, it is believed to have been founded in the 10th century. It was successively dominated by Lithuanians (1336), Poles (1569), Russians (1791) and from 1920 to 1939 it was again included in Poland and known as Luck. The town was occupied by Russian troops in 1939 and by the Germans in 1941; in 1945 it became part of the U.S.S.R. Lutsik is the centre of an agricultural region and manufactures farm machinery and clothing, and processes foodstuffs, timber and leather. There is a pedagogic institute.

(R. A. F.)

LUTTRELL, HENRY (c. 1765-1851), English wit and writer of light social satire. The illegitimate son of Henry Lawes Luttrell, 2nd earl of Carhampton, he entered society under the patronage of the duchess of Devonshire and became famous for the brilliance of his conversation, being described by Byron as "the most epigrammatic conversationalist I ever met," and by Lady Blessington as the one talker "who always makes me think." His *Letters to Julia in Rhyme* (1823; expanded from *Advice to Julia*, 1820), in neat couplets, contain lively descriptions of a thunderstorm in Hyde park, evenings at Almack's and the opera and excursions to Richmond and Hampton Court, but with an undertone of criticism—

Folks rise and flourish and are undone
Nowhere so quickly as in London.

He also published *Crockford House* (1827), a satire on the fashion for high play. He died in London, Dec. 19, 1851.

LÜTZEN, BATTLE OF, a battle of the Thirty Years' War (q.v.), fought outside Lützen in Saxony on Nov. 16 (new style 6, old style), 1632. After his inconclusive battles against the Swedes under Gustavus II Adolphus around Nürnberg in September, Wallenstein, the Holy Roman emperor Ferdinand II's general, moved northward to take up winter quarters in Upper and Lower Saxony. He also planned to exert pressure on the elector John George I of Saxony and to protect Poland against the Swedish contingent stationed in Prussia. On the news of the dispatch by Wallenstein of Gallas and Pappenheim on separate missions, Gustavus, wishing to help his North German allies, to beat Wallenstein and to keep watch on the events in Poland abandoned his plan to attack Bavaria. He marched rapidly through Thuringia and, reinforced by Bernhard of Saxe-Weimar and other detachments, offered Wallenstein battle between Naumburg and Leipzig. The Swedes numbered about 14,000, the imperial forces (without Pappenheim) about 12,000 men.

Gustavus' hope for an early decision was dashed by a thick fog that delayed the Swedish attack until nearly 11 A.M., by which time Pappenheim, hastily summoned back by Wallenstein, had arrived with his cavalry. Pappenheim's tempestuous charge was beaten off, and he was mortally wounded. But Wallenstein's centre, led by Ottavio Piccolomini, was victorious, and Gustavus was killed while trying to rally his men. The Swedes were on the point of giving way when Bernhard assumed command and retrieved the situation all along the line, capturing the whole artillery of the imperial forces. The arrival of Pappenheim's infantry permitted Wallenstein to disengage himself in good order.

(S. H. S.)

LÜTZOW, ADOLF, FREIHERR VON (1782-1834), Prussian cavalry officer, best known as an organizer of guerrilla-type forces during the Napoleonic Wars, was born in Berlin on May 18, 1782, and entered the Prussian army in 1795. He took part in Ferdinand von Schill's abortive rising against the French in

Germany in 1809. In Feb. 1813, at the outbreak of the War of Liberation, he obtained permission from Gerhard von Scharnhorst (the chief of staff) to raise a "free corps" or a guerrilla force of non-Prussian volunteers to operate in the rear of the French army. His troops, who eventually numbered 3,000 and were named the "black band" after their uniform, met with a disaster at Kitzen (near Leipzig) on June 17 because poor communications had prevented their being notified of the armistice of June 4: caught on the wrong side of the demarcation line, they were practically annihilated. Lützow however reorganized the force, which then fought at Gadebusch, at Göhrde (where he was wounded) and at the siege of Jülich. The black band was of little military value but owed its reputation to the enlistment of public figures such as the poets Joseph von Eichendorff and Theodor Körner.

At Ligny (June 16, 1815) Lützow led the 6th Uhlans in an abortive charge which ended in their being routed by French cavalry. Lützow was captured, but escaped at Waterloo (June 18). Some years afterward, this incident led to his sending a challenge to Blücher, who had made some disparaging remarks about the conduct of the 6th Uhlans at Ligny. Lützow died in Berlin on Dec. 6, 1834.

See K. von Lützow, *Adolf Lützow's Freikorps* (1884). (C. N. B.)

LUWIANS, an extinct people of ancient Asia Minor, also known as Luites. Their language, Luwian (Luvian, Luish), is known from cuneiform texts of the 14th and 13th centuries B.C. found at Boğazköy, the capital of the Hittites (*q.v.*), where it is referred to by the adverb *luwili* (*lu-u-i-li*), "in Luwian." This language is related to, but distinct from, Hittite; with Hittite and Palaic it belongs to the Anatolian group of Indo-European languages (see ANATOLIAN LANGUAGES). The language written with the so-called Hittite hieroglyphs, which were used for inscriptions from the 14th to the 7th century B.C., is very close to Luwian, probably nothing but a dialect of it; and the Lycian language, written in a variety of the Greek alphabet in the 5th and 4th centuries B.C., is equally related and may go back to still another dialect of Luwian. Personal names that have been claimed as Luwian are attested in Asia Minor from the 19th century B.C. to the Roman period.

Language.—Luwian shares with Hittite and Palaic the following characteristics: (1) it has only two genders, masculine-feminine (*genus commune*) and neuter; (2) the verb has a present and a preterit tense in the indicative mood and an imperative but no other moods; and (3) it has an active and a middle form. The main differences between Luwian and Hittite are: (1) replacement of the genitive by a possessive adjective in *-assi*; (2) a case in *-ti* serving as ablative and instrumental; (3) plural of the *genus commune* in *-nti*: nominative in *-nzi*, accusative in *-nza* (in cuneiform Luwian only, not in hieroglyphic). (4) The verb has 1st singular present in *-wi* (against Hittite *-mi*), 3rd singular in *-ti*, plural in *-nti* (against Hittite *-zi*, *-nzi*), preterit *-ta*, *-nta* (against Hittite *-t*, plural *-er*). (5) In the vocabulary, Luwian has a set of connective particles different from the Hittite. Some words are identical with or very close to their Hittite counterparts (often replacing Hittite *e/i* by *a*); others are different, such as *tati*, "father," against *atta*; and *massana*, "god," against *siuni*, etc.

Distribution and History.—The Hittite laws, datable to about 1500 B.C., mention Luwia as a foreign country. One copy of the laws replaces "Luwia" by "Arzawa." The term Luwia is not used thereafter, whereas Arzawa (Arzava) is frequent as the name of a large region comprising several principalities, probably in southwestern Asia Minor. If the variant means that "Luwia" and "Arzawa" were roughly synonymous (the older term standing for or at least including Arzawa), then Luwians would have lived in the southwest. The language is, however, also attested in Kizzuwatna, a country including the Cilician plain in the south, so that the old term Luwia may include that region also. Both Arzawa and Kizzuwatna were independent kingdoms during the Old Hittite period (c. 1700–1370 B.C.) but later became vassals of the Hittite empire, Kizzuwatna under the ruler Suppiluliumas (c. 1370 B.C.) and Arzawa under his son, Mursilis II. Apparently Luwians both shared in and contributed to Hittite civilization.

The Luwian texts found in the Hittite capital (mostly magic spells) as well as the use of hieroglyphs throughout the empire and the appearance of Luwian loanwords in Hittite texts testify to the penetration of the Hittite empire by Luwians, a process that increased toward the end of the empire, in the 13th century.

Since Luwians lived in southwestern and southern Anatolia, attempts have been made to ascribe to them certain types of pottery found in those regions, but these attributions remain hypothetical. Similarly, place names formed with the suffixes *-nd-* and *-ss-*, which are found in parts of Asia Minor and in Greece, have been claimed as Luwian. Closer examination of the place names occurring in Hittite texts has shown, however, that many of them are not Luwian and that they also occur outside the Luwian area. Personal names of Luwian type first occur in limited numbers toward the end of the Assyrian merchant colony period (c. 1800 B.C.). They were common in the Hittite period and survived until Roman times.

After the downfall of the Hittite empire (c. 1190 B.C.) hieroglyphic inscriptions in Luwian are common in southeastern Anatolia and northern Syria. Their appearance in Syria indicates an expansion of Luwians into regions not previously held by them. The history of the Luwians in the 1st millennium B.C. thus is the history of the so-called Late Hittite principalities—Tabal (biblical Tubal) around Kayseri, Tuwanuwa (classical Tyana), Gurgum with capital Marqasi (Maraş), Milit (Melitene, Malatya), Carchemish on the Euphrates, Hattina (the plain of Antioch) and Amatu (Hamath). The hieroglyphic inscriptions are of votive character, containing little more than the names of rulers, sometimes with genealogies. Most historical information about these states comes from the annals of Assyrian kings, who repeatedly raided them and imposed tributes, until Sargon II (722–705 B.C.) incorporated them as provinces into his empire. Most Syrian states were conquered by Aramaeans prior to the Assyrian conquest; but in the Anatolian principalities (Tabal, Tuwanuwa, Milit) and above all in Carchemish, the most important kingdom of the group, Luwian proper names and hieroglyphic script remained in use until the end. From roughly 700 B.C. also is dated the bilingual inscription in Phoenician and hieroglyphic Luwian discovered at Karatepe in eastern Cilicia. What little is known about Lycia (*q.v.*), finally, comes from classical sources.

Religion and Civilization.—Luwian gods were incorporated into the pantheon of the Hittites. On the whole, the beliefs of the two peoples were very similar so that their gods could easily be identified with one another. The chief god in both systems was a god of thunderstorm and rain, called Tarhunt in Luwian. The Luwian sun god was called Tiwat; the moon god had the same name, Arma, in both languages. Other gods worshiped in Luwian belong to different ethnic groups; e.g., Kupapa, the main goddess of Carchemish. A Luwian dialect was used in the cult of the gods of the town of Istanuwa (location unknown). The presence of Luwian magical rituals in the Hittite capital indicates that Luwians had a certain reputation as magicians. In the late hieroglyphic inscriptions some of the gods known from earlier cuneiform texts recur. In these inscriptions the gods are asked to punish anyone who might damage the object or the text.

As stated earlier, the Luwians partook in the general Hittite civilization. Whatever institutions or cultural traits may have been typically Luwian remains to be determined. The small Luwian states of the 1st millennium carried on the Hittite tradition, as witnessed by the traditional Hittite names of some of their rulers, such as Lubarna, Sapalulme, Katuzili or Muwatalli, and by the name "Hittite" given them by both the Assyrians and the Israelites of the period of the monarchy. The art of these states combines Hittite motifs with others of more generally near-eastern origin; its style, which differs markedly from that of the Hittite empire, was influenced by that of the Aramaeans and, later, of the Assyrians, so that it is hard to identify specifically Luwian characteristics. On the whole it appears that the main importance of the Luwians lies in the continuation of Hittite tradition after the downfall of the empire.

LUXEMBOURG, FRANÇOIS HENRI DE MONTMORENCY-BOUTTEVILLE, DUC DE (1628-1695), French marshal, the great opponent of William III of Orange in the wars of Louis XIV's reign, was born in Paris on Jan. 8, 1628. He was the posthumous son of François de Montmorency, comte de Boutteville, who had been executed in June 1627 after killing his opponent in a duel. The dead man's father's cousin, Charlotte de Montmorency, princesse de Condé, brought the boy up; and her son, the Great Condé, remained devotedly attached to him and to his sister Isabelle, later duchesse de Châtillon. Boutteville was hunchbacked and physically weak at first, but Condé trained him for war and recommended him for a regiment after the battle of Lens (1648).

When the imprisonment of Condé in 1650 led to the second war of the Fronde (*q.v.*), Boutteville joined Turenne in rebellion and was captured in the battle of Rethel. In the third war of the Fronde he held Bellegarde on the Saône for Condé until June 1653, after which he joined Condé in the Spanish army. He returned to France after the peace of the Pyrenees (1659).

Boutteville came to be styled duc de Luxembourg through his marriage (1661) with Madeleine Charlotte de Clermont-Tonnerre, great-granddaughter of François de Luxembourg, who had been created a peer of France with the title of duc de Piney, in 1581. Assuming the name of Luxembourg, he secured recognition of his French peerage in 1662, thanks to Condé. This promotion provoked envy, and there was much opposition to his return to the French army, which Condé secured in 1668.

When war with Holland broke out in 1672 (*see DUTCH WARS*), Luxembourg was at first sent to command German troops as field marshal of the bishop of Cologne, Maximilian Henry of Bavaria; then he was left for two winters in command at Utrecht against the forces of William of Orange. When Holland had to be evacuated, his skill in retreating from Utrecht in face of large forces was generally acknowledged, and in 1674 he fought at Seneffe. Thus when Turenne was killed he was one of the eight marshals appointed to succeed him (July 1675). The marquis de Louvois favoured him, though Louis XIV remembered his rebellion during the Fronde and also disapproved of his private morals. When in 1676 Luxembourg took Condé's place in the Rhine command, his military reputation fell, as Charles V of Lorraine captured Philippsburg from him. Little credit was given to his share in the Flanders campaign of 1677-78; and his defeat of William at St. Denis near Mons (Aug. 1678) brought him more criticism than honour, since his losses were heavy and the battle took place three days after the conclusion of peace.

When Luxembourg returned to Paris his name was being associated with the scandals that developed into the Affair of the Poisons. On Jan. 24, 1680, the king sent him to the Bastille on charges of sacrilege and the practice of "black arts"; and on his acquittal he was exiled from Paris and Versailles (May). Condé interceded, however, and in 1681 Luxembourg was recalled to court; but when war was resumed in 1688 (*see GRAND ALLIANCE, WAR OF THE*), he was not given a command.

The defeat of the marshal d'Humières (Louis de Crevant) at Walcourt in 1689 left the king with no alternative but to turn to Luxembourg. In April 1690 Luxembourg took command in Flanders; and on July 1 he crushed George Frederick of Waldeck's smaller army at Fleurus. In the next four years he fully matched William of Orange: he took Mons (April 1691), covered the successful siege of Namur (May-July 1692) and defeated

William in the great battles of Steenkerke (Aug. 3, 1692) and Neerwinden (July 29, 1693). His battles, from which he sent so many captured flags to be hung in the cathedral in Paris that the prince de Conti (François Louis de Bourbon) called him the *tapisserie de Notre Dame*, were marked by the tactical vigour he inherited from Condé; and if they decided nothing, this could be attributed to the king's system more justly than to the marshal's alleged apathy when he was not on the field of battle. After a last campaign in 1694 Luxembourg returned in high honour to Versailles, but died suddenly on Jan. 4, 1695.

See P. de Ségur, *La Jeunesse du maréchal de Luxembourg* (1900) *Le Maréchal de Luxembourg et le prince d'Orange* (1902) and *Les Dernières Années du maréchal de Luxembourg* (1904). (I. D. E.)

LUXEMBOURG (GRAND-DUCHÉ DE LUXEMBOURG). A sovereign grand duchy of Europe, Luxembourg is bounded on the north and west by Belgium, on the east by Germany and on the south by France. It has an area of 2,586.4 sq.km. (999 sq.mi.), with maximum distances of 82 km. (51 mi.) from north to south and 57 km. (35 mi.) from east to west. The country comprises part of the southern Ardennes uplands and part of the adjoining plateau of Lorraine, both areas being drained eastward to the Moselle by the Sûre and its tributaries. The old name Lützelburg and the dialect name Letzeburg, still used, are variants derived from an early form, Lucilinburhuc ("little fortress").

Physical Geography.—The Ardennes region (or Oesling) in the north, forming one-third of the country, is a plateau consisting of Devonian slates, grits and quartzites varying in altitude from 1,300 to 1,600 ft., although a few summits rise above 1,800 ft. It is dissected by deep, winding valleys in which the streams are entrenched. The steep valley slopes are heavily wooded, but the upland surface is mostly cultivated and supports many villages. The rest of the country, consisting largely of Triassic marls and Lower Jurassic sandstone and clays, forms a lower plateau with a mean altitude of 900 ft.; it is called the Bon Pays or Gutland because of its superior agricultural conditions. In the southwest Lower Jurassic rocks containing iron stone extend from Lorraine into the grand duchy, providing the basis for an important iron and steel industry.

The climate of Luxembourg is transitional between the maritime type of northwestern Europe and the semicontinental type experienced farther into the interior. The Ardennes, however, has cool summers, relatively severe winters and a greater precipitation than the Bon Pays, although the highest rainfall (nearly 40 in. a year) occurs in the extreme southwest. The lowest rainfall (less than 27 in.) is found along the Moselle valley. Mean monthly temperatures for Luxembourg city range from 0° C. (32° F.) in January to 17° (63°) in July. Until the early 18th century Luxembourg was almost entirely covered with forest, mainly of oak and beech, and during the period of French rule (1795-1815) it was called the Département des Forêts. Much of the forest was later removed but oak in the Ardennes and beech in the Bon Pays remain the dominant woodland trees. With afforestation schemes for softwood timber, coniferous woods are increasing.

History.—At the time of the Roman conquest, between 57 and 50 B.C., the area of what is now Luxembourg was inhabited by a Belgic tribe, the Treveri. The population received some Roman infusion during the occupation. After A.D. 400 Germanic invaders began to penetrate the region, and it became part of the Frankish kingdom of Austrasia and later of Charlemagne's empire. By the treaty of Verdun (843) the area was included in the central division of the three into which that empire was split, but it became an independent entity in 963 under Siegfried, count of Ardennes. Conrad (d. 1086), a descendant of Siegfried, took the title of count of Luxembourg about 1060, and his successors enlarged their possessions, chiefly by marriage. Conrad's great-granddaughter, the countess Ermesinde (1196-1247), granted charters of franchise to most of the important towns of the county. Her great-grandson Henry IV became German king in 1308 and Holy Roman emperor as Henry VII, and the Luxembourg dynasty was continued on the imperial throne in the persons of Charles IV, Wenceslaus and Sigismund (d. 1437). *See*

1354 the emperor Charles IV made the county a duchy. The French branch of the house of Luxembourg descended from Waleran of Ligny, younger son of Ermesinde's son Count Henry II.

In 1441-44 Sigismund's niece Elizabeth of Görlitz ceded Luxembourg to Philip the Good of Burgundy. With the Netherlands (*q.v.*) it later passed to the Habsburgs. Spanish domination began in 1555-56, with the abdication of the emperor Charles V. In the revolt of the Low Countries against Philip II, Luxembourg took no part; it was to remain united with what is now Belgium as part of the Spanish Netherlands. During the 17th century the French under Louis XIV annexed several towns of the area, and Luxembourg itself was captured in 1684 but was returned 13 years later to Spain by the treaty of Rijswijk. In 1713 Luxembourg with Belgium passed from the Spanish to the Austrian Habsburgs. It was occupied by the French republic in 1795 and became a *département* of France under Napoleon.

The congress of Vienna in 1815 gave Luxembourg as a grand duchy to William I, king of the Netherlands. Districts lying to the east of the Moselle, Sûre and Our were handed over to the king of Prussia. Luxembourg had the legal position of an independent state, in personal union only with the Netherlands, and was included within the German confederation. However, William I succeeded in uniting the grand duchy *de facto* and *de jure* with his kingdom as its 18th province. When the Belgian provinces revolted against William, most of the country, with the notable exception of the town of Luxembourg itself (then garrisoned by Prussians), sided with them. In 1831 the powers divided the country into two parts, of which the larger (now the Belgian province of Luxembourg) went to Belgium and the smaller, in the east, was retained by William I, who, however, refused to accept the decision until 1839. From that year until 1867 the grand duchy was administered separately from the Netherlands. It received from William II a restricted constitution in 1841 and a more liberal one in 1848. After the dissolution of the German confederation in 1866 the link which bound Luxembourg to Germany was broken, but the Prussian garrison remained in the capital. In 1867, by the treaty of London, this garrison was withdrawn; the neutrality of the grand duchy was guaranteed by the powers and its sovereignty was vested in the house of Nassau. On the death of William III of the Netherlands in 1890 without a male heir, the grand duchy passed, in accordance with the Nassau Succession agreement (1783), to Adolphus, duke of Nassau-Weilburg (d. 1905), who was succeeded by his son William (d. 1912). In 1914 the neutrality of Luxembourg was violated by Germany. On Jan. 15, 1919, after the duchy's liberation, William's daughter, the grand duchess Marie Adélaïde, who had shown pro-German sympathies, abdicated in favour of her sister Charlotte. Charlotte (b. 1896) was married in 1919 to Prince Felix of Bourbon-Parma. Prince Jean, their eldest son (b. Jan. 5, 1921), was married on April 9, 1953, to Princess Joséphine Charlotte, daughter of former king Leopold III of Belgium, and on April 16, 1955, she gave birth to a son, Henri. On May 4, 1961, Prince Jean was installed as *lieutenant-représentant* of Charlotte, and began to exercise all her constitutional powers. Her abdication in favour of the prince was announced in 1964.

Luxembourg was occupied again by the Germans from 1940 to 1944, during World War II. Civil government was finally re-established in Sept. 1944. Though it suffered some damage in the fighting of 1944, the industrial capacity of Luxembourg was not seriously impaired and the country soon regained its prosperity. Perpetual neutrality, guaranteed by the treaties of 1839 and 1867, was abandoned in 1948 when the duchy became a signatory to the Brussels and North Atlantic treaties. Luxembourg, which entered into a customs union with Belgium in 1922, became, after World War II, a member of Benelux (*q.v.*) and of the European Economic Community. (See ECONOMIC UNION.)

Population.—The population of Luxembourg was 309,359 at the census of 1960 and in 1962 was estimated at 319,526. The rural population, living mostly in compact villages, exceeds the urban population which is largely concentrated in the capital and the metallurgical district. The chief towns are Luxembourg

(pop. [1960] 69,830), the capital, Esch-sur-Alzette (27,330) and Differdange; smaller ones include Echternach, Diekirch, Ettelbruck, Vianden, Wiltz, Grevenmacher and the spa-resort Mondorf-les-Bains. The inhabitants include about 40,000 foreigners, chiefly from neighbouring countries and from Italy, many being employed in iron ore mining or as officials of international organizations in the capital.

The people are essentially a peasant stock, and are inspired by a strong sense of nationality. They form a bilingual nation and possess, besides French and German, their own spoken dialect. French and German became official languages in 1830. Education is given in both tongues, and the native speech, Letzeburgesch (a Moselle-Franconian dialect of the West Middle German group), is used by all classes. In 1939 it was made the third official language. More than 97% of the inhabitants are Roman Catholic. An episcopal see was created in 1870. Protestants (chiefly Lutherans) and Jews are estimated at 3,000 and 1,000, respectively.

Administration and Social Conditions.—The grand duchy is a constitutional monarchy with a hereditary ruler. Failing legal issue a successor is elected by a chamber of deputies. The constitution, modeled on that of Belgium, was proclaimed in 1868 and modified in 1919, 1948 and 1956. Sovereignty is vested in the people, and a parliamentary regime exists. Besides embodying such concepts as individual liberty, legal equality, freedom of religion, expression and association, and the right to employment, the constitution asserts such needs as the provision of medical services and social security. In 1956 the possible temporary transfer of certain sovereign powers to supranational organs was accepted.

The ruler exercises executive power through a ministerial council (cabinet), has certain judicial functions and possesses the right to propose legislation. The ruler also makes most appointments to military and civil posts and is commander of the armed forces. The ministerial council (constitutionally of at least three members, and numbering seven in the early 1960s), headed by a minister of state (prime minister), is the governing body responsible to the chamber of deputies. Its members cannot be deputies, but have the right to address the chamber and can be summoned before it. This council is nominated and can be dissolved by the sovereign.

A council of state (21 members nominated largely by the ruler) has many of the functions of a second chamber, and is in fact a political as well as a judicial consultative body. It may pass an opinion on all matters of public interest. Its opinion on draft legislation must be expressed before discussion in the chamber, and indeed it helps to shape much legislation. It determines the order in which bills are discussed. It also advises on administrative matters, and from its members is chosen a committee (*comité du contentieux*) which acts as a final court in disputes relating to the powers of the administration.

The chamber of deputies (comprising not more than one member for every 4,000 voters and not less than one for every 5,500) has been elected since 1919 by all adult citizens. Voting is obligatory and is carried out according to a proportional representation system within four constituencies. Deputies, who must be over 25, serve for five years. The chamber can initiate legislation and amend draft measures, all decisions being taken by a majority vote. The elections of 1959 returned 21 members of the Christian Social party, 17 Socialists, 11 Democrats and 3 Communists.

Six consultative chambers (*chambres professionnelles*), representing agriculture, handicrafts, commerce, civil servants, private employees and labour, have the right to express their opinions on measures concerning their respective occupations before these are passed by the chamber.

Local Government.—The basic unit of local government is the commune, administered by an elected council, with a burgomaster and two aldermen (*échevins*) appointed by the sovereign as executive heads. The council is responsible for such matters as public undertakings, elementary education and health, and also acts as an instrument of the central authority. It can be dis-

missed by the sovereign. The 126 communes are grouped into 12 cantons, and these in turn into 3 *arrondissements administratifs*, each under a *commissaire de district*, who represents the ministry of the interior and is appointed by the sovereign.

Legal System.—The law, based on that of Belgium, is codified and its administration is centralized in a minister of justice. Tribunals can be set up only by law, and judges are nominated by the ruler. Within each canton a *juge de la paix* has summary jurisdiction over breaches of police regulations and minor civil cases. Above come two *tribunaux d'arrondissements* which serve as courts of appeal and try more serious offenses. Finally there is a *cour supérieure* which acts as a court of appeal and of cassation. Periodically this body appoints a *cour d'assises* of six judges (also acting as jurors) to try major offenses; their verdict is by majority vote with acquittal in case of equal division.

In 1930 a central police force was created, headed by a director. Under him is a commissioner in each of three police districts, with local commissioners within the communes. The police is supplemented by a small force of gendarmes.

Education.—Education is compulsory between 6 and 13 years of age, and *écoles gardiennes* (nursery schools) also exist. Free instruction is given in ordinary and advanced state primary schools, and by means of continuation classes. There are also free secondary schools where instruction is given in French for pupils from about 12 years of age. Higher education is provided by institutions or centres for training in arts and crafts, literature and sciences, technical subjects, agriculture and teaching. In the early 1960s the International University of Comparative Sciences had faculties of law and economics only, but students could continue their education in foreign universities.

Social Security.—After World War II social security was extended by successive laws and regulations so that provision for industrial accidents, sickness and unemployment exists for most classes. Other benefits include birth, family and unemployment allowances. There is a minimum legal wage. The protection of health has been increasingly promoted by legislation, controlling and organizing the health services and improving labour conditions and public hygiene. Patients have to make only a small contribution to the cost of medical treatment.

Defense.—In 1944 obligatory military service was introduced; service is for nine months. In 1948, when neutrality was abandoned, the duchy's standing force was integrated into the military organizations set up by the Brussels and North Atlantic treaties. In the early 1960s it consisted of about 3,000 men.

Economy.—The economy of Luxembourg is dominated by the iron and steel industry, which accounts for nearly four-fifths of the gross national product, but agriculture is still the main source of employment. Apart from iron ore, mineral output (chiefly slates and building stone) is slight. With 34,804 ac. under forest, timber production is of some importance, although a considerable net import is necessary. Manufacturing is increasing and to the older industries of engineering, pottery, clothing and leather, new ones such as cement, chemicals and tire manufacturing have been added. There is also a rapidly growing tourist industry.

Though without coal resources, Luxembourg is well supplied with electricity, chiefly from the steelworks in the south. Two small supplementary hydroelectric stations have been built, at Esch-sur-Sûre and at Rosport on the Moselle, and another was constructed near Vianden on the Our in the early 1960s.

As a member of Benelux, Luxembourg is economically integrated with Belgium and the Netherlands, all three being members of the European Economic Community. The monetary unit is the Luxembourg franc, at par with the Belgian franc.

Agriculture.—In the early 1960s there were about 57,184 ac. of farmland giving direct employment to about 35,000 people. Three-quarters of the farms were of less than 50 ac., being owned by those who worked them. Mixed farming is the rule, in both the Oesling and the Bon Pays, with an emphasis on livestock, especially Frisian cattle. Crop yields, though lower than in neighbouring countries, owe much to the use of basic slag fertilizer, a by-product of the steel industry. The division of holdings into separate *parcelles*, sometimes distant from the village,

is disadvantageous but methods were being improved and the number of tractors almost quintupled between 1950 and 1960. In amount, arable land generally exceeds that under pasture, the area under crops being fairly evenly divided between grain, roots and green fodder such as clover and lucerne. Wheat, rye and potatoes are grown primarily for human consumption, and oats, barley and roots for animals. Cattle raising, increasingly for dairying, is the main enterprise, and pigs are also important, hams from the Ardennes being a specialty. Sheep have declined greatly in numbers. The specialized cultivation of rose trees in the Alzette valley, largely for export, has dwindled, but viticulture along the Moselle and lower Sûre valleys provides a considerable output of dry white wine. Many of those engaged in the iron and steel industry in the south work small part-time holdings.

Iron and Steel.—Steel production is based on exploitation of the ore deposits (*minette*) extending from Lorraine into the southwestern corner of the grand duchy. The ore, covering about 9,000 ac., is easily worked but of low grade, averaging barely 30% iron and containing phosphorus. Of the approximately 30 mines, half are opencast, and the output of ore is about 6,500,000 tons annually. Although pig iron was produced before 1870, it was not until the introduction of the Thomas-Gilchrist basic process in 1879 that this phosphoric ore could be used for making steel. Thereafter, large units were established on the ore field, including blast furnaces, steel converters and rolling mills. These are situated at Esch-sur-Alzette, Dudelange, Differdange and Rodange, all close to the French frontier, and another plant is at Dommeldange just north of the capital. Fuel requirements are met by imports of coke from the Ruhr and smaller quantities from Belgium and the Saar, ore and pig iron being exported to Germany and Belgium. Steel output is about 3,500,000 tons annually, making Luxembourg a leading producer. Luxembourg is a member of the European Coal and Steel Community and, despite rather high production costs, 95% of the steel output is exported. The reserves of ore, far less than those of Lorraine, are estimated at 300,000,000 tons. Important by-products of the industry are basic slag fertilizer and the generation of electricity from waste furnace gases.

Communications.—The state-owned railway system forms a link between Belgium and the Netherlands, France, Germany and Switzerland and carries much international traffic. About half the mileage is double-tracked. Electrification of the main Arlon-Luxembourg-Thionville (France) line was completed in 1956 and diesel trains are being brought into use. The grand duchy is served by a good system of roads, about half of which are state highways connecting all the principal centres. The remainder includes those belonging to the communes but maintained by the state, two grades of local roads owned and maintained by the state and two grades of local roads owned and maintained by the communes. Air transport is rapidly increasing, especially between the city of Luxembourg and major European centres. The enlarged, modernized airport at Sandweiler, less than 4 mi. E. of the capital, is equipped to handle modern jet aircraft. The canalization of the Moselle, begun in 1958, was completed after 1965. The postal, telephone and telegraph systems are owned and operated by the government. The radio and television stations are privately owned and Radio Luxembourg broadcasts are beamed to a wide area of Europe.

Current history and statistics are summarized annually in the *Britannica Book of the Year*.

LUXEMBOURG, the largest and most southerly of the nine provinces of Belgium, consists of five administrative *arrondissements*, 20 judicial cantons and 233 communes. Area 4,419 sq.km. (1,706 sq.mi.). Pop. (1961) 216,848. It became a province of Belgium in 1831, before which it was part of the grand duchy of Luxembourg whose history it shared. Much destruction was caused in the northeast during the latter part of World War II.

Three-quarters of the province consists of the Ardennes (*q.v.*), drained by three tributaries of the Meuse: the Ourthe in the north, the Semois in the southwest and the headstreams of the Lesse in the west. In the extreme south an area of about 1,000 sq.km. (400 sq.mi.) comprises Belgian Lorraine.

Much of the Ardennes region lies within the province, the plateau consisting mainly of Devonian sandstones, quartzites and slates. The highest point in the northeast is the Baraque Fraiture (1,968 ft.) on the Plateau des Tailles between the Ourthe and Amblève valleys; the Forêt de St. Hubert between the Ourthe and the Lesse attains 1,837 ft. Most of these plateaus form rounded, heath-covered summits separated by shallow depressions containing peat bogs or wet moorland. Woodland occupies about one-third of the total area; there are oak-birch and beech forests in the valleys, and plantations of spruce and Scots pine on the plateaus. The streams on the plateaus flow mostly in deep valleys, the Semois forming a series of deeply incised meanders in the south.

Belgian Lorraine affords a marked contrast. In the east a narrow tongue of clayey red Keuper sandstones and conglomerates extends for 15 mi. along the southern margin of the Ardennes. Then follows a succession of Jurassic calcareous sandstones, limestones, shales and marls, trending in parallel outcrops from west to east. The highest point in Belgian Lorraine is the Hirtzenberg (1,526 ft.). The sandstones and limestones form north-facing scarps. In the north is the Côte des Grès de Luxembourg of yellowish Lower Lias calcareous sandstone. A few miles farther south is the Côte des Macignos d'Aubange, also calcareous sandstone, rising to 1,348 ft. Along the Franco-Belgian frontier lies the Côte Calcaire de Longwy whose highest point in Belgium is 1,322 ft. Between these ridges occur clays, marls and shales of the Middle and Upper Lias, through which the Semois and various tributaries of the Chiers drain to the Meuse.

The Ardennes is of limited agricultural value, with its thin acid soils, considerable areas of bog, heavy precipitation, high cloud incidence and frequent frosts. Most of the small area of farmland is under permanent pasture, raising beef cattle to be sent to the lowlands for fattening, with dairy farming in the sheltered valleys and a small amount of arable farming, chiefly oats, rye, trefoil and potatoes. On alluvial flats in the Semois valley smallholders grow tobacco intensively with heavy fertilization.

Nearly half of Belgian Lorraine is still largely wooded, mainly birch and pine on the escarpments and patches of beech and oak on the heavier clays. Less than one-third is farmland and two-thirds of this is under pasture, the rest growing wheat, potatoes and fodder crops. About one-third of the cattle are dairy animals. Figs are raised and some fruit is grown.

Industrially the Ardennes is of little importance. Timber is cut and exported, and quarrying of quartzite for road metal is widespread. A few slate quarries still operate. A small portion of the French Lorraine iron ore field extends into Belgium, but in the early 1960s there was only one active mine, producing about 140,000 tons annually. The ore being too friable to stand transport, blast furnaces were built at Musson and Halanzy and a steelworks at Athus.

The Ardennes has a population density of less than 100 per square mile. A few small towns stand on the plateau, mainly on the railway lines. They are market centres and tourist re-

sorts, notably Houffalize at about 1,100 ft., La Roche-en-Ardenne on a meander core of the Ourthe valley, St. Hubert, Libramont, Neufchâteau and Vielsalm. Several pleasant little towns (Florenville, Chiny) are in the Semois valley. The population density of Belgian Lorraine is about 160 per square mile in the *arrondissement* of Arlon, but less than 130 in that of Virton. The population is mostly grouped in small, nucleated villages in the vales. The only town of any size is Arlon (13,275 in 1959), on a hill overlooking the headstreams of the Semois. It is the headquarters of the province and a market centre. The meeting point of 11 main roads, it is also the frontier station for the international Brussels-Namur-Luxembourg-railway line. (F. J. M.)

LUXEMBOURG (dial. LETZEBURG, "Little Fortress"), capital of the grand duchy of Luxembourg, is situated on the Alzette, a tributary of the Sûre. Pop. (1961) 71,653. The city stands on a sandstone plateau into which the Alzette and its tributary, the Petrusse, have cut deep, winding ravines. Within a loop of the Alzette a rocky promontory called the Bock (Bouc) formed a natural defensive position recognized by the Romans. The medieval town developed around it. The old town with the palace (1572), town hall and cathedral of Notre Dame (1613) occupied the plateau, spreading to the west later, and the suburbs of Grund, Clausen and Pfaffenthal developed in the valley below. The cathedral contains the remains of John the Blind, king of Bohemia and count of Luxembourg (d. 1346). The fortress, gradually elaborated to become the strongest in Europe after Gibraltar, was dismantled in 1867. On the western fringe of the old town attractive parks, in which are the studios of Radio Luxembourg, have replaced earlier fortifications. Beyond, residential districts spread farther westward. Across the gorge of the Petrusse a viaduct (Pont Adolphe) gives access to the area of modern hotels, shops and offices on the Plateau Bourbon and around the railway station to the south, near which is the industrial suburb of Hollerich. Other viaducts carry the railway through the town to the north. At Hamm to the east is a military cemetery containing the graves of more than 5,000 U.S. soldiers including that of Gen. G. S. Patton. A little farther out is the airport. At Eich, a northern suburb, iron foundries stand on the site of the first ironworks (1845) to use the ore from the southern part of the country. Luxembourg, for long an important road and railway focus and financial centre, is the seat of the high authority of the European Coal and Steel Community. Two annual fetes are celebrated, one on the Sunday preceding Ascension day in honour of Our Lady of Luxembourg, and the other in late August or early September, the *Schobermesse* ("tent fair"), dating from 1340. (K. C. E.)

LUXEMBURG, ROSA (1870?–1919), one of the most important women in the history of international socialism and a revolutionary who might have had a decisive influence on the development of the working-class movement in Germany, was born at Zamosc in Russian Poland on March 5, 1870 (or perhaps, according to a statement of her own, 1871), of a Jewish merchant family. On leaving the Warsaw *Gymnasium* she joined the Polish revolutionary socialist party "Proletariat" but fled abroad in 1889 to escape imprisonment. In Switzerland she studied natural sciences and political economy at Zürich and took her doctor's degree with the dissertation *Die industrielle Entwicklung Polens* (1898). In Switzerland also she met the Russian champions of Marxism, G. V. Plekhanov, Pavel Axelrod and Vera Zasulich; most important was her close relationship with Leo Jogiches. Together with Jogiches she took over the leadership of the Social Democratic Party of the Kingdom of Poland and Lithuania, which had been formed in 1893 after quarrels among the Polish Socialists. Contrary to the patriotic attitude of the Polish Socialist party, Rosa Luxemburg repudiated the idea of reconstituting an independent Polish national state: she insisted that the Polish proletariat should not aim ultimately at the liberation of Poland from Russia but should serve the higher socialist task, namely the elimination of tsarist absolutism. This attitude foreshadowed her later controversy with Lenin over the right of national self-determination (the importance of which she consistently underrated).

Rosa Luxemburg obtained German nationality through a fictitious marriage and settled in Germany in 1898 in order to work with the German Social Democratic party, the largest and strongest party of the Socialist International. Her activities as a journalist and her spirited behaviour at party congresses soon made her one of the best-known leaders in the fight against the revisionist ideas of Eduard Bernstein (*q.v.*). She opposed Bernstein's theses mainly in a series of newspaper articles which were republished as a pamphlet, *Sozialreform oder Revolution* (1899). During the Russian revolution of 1905 she wanted to take her place at the head of the fighting Polish proletariat, but a serious illness prevented her leaving for Warsaw before the end of the year. In Poland she was imprisoned in the spring of 1906 but was released on bail after a few months because of the state of her health. Back in Berlin she began a new career as teacher at the party school. This educational activity helped her to produce her main works: *Die Akkumulation des Kapitals* (1913), an important contribution to the Marxist theory of imperialism; and *Einführung in die Nationalökonomie*, published after her death by Paul Levi in 1925. (See MARXISM.)

In the decade preceding World War I, Rosa Luxemburg came to oppose ever more sharply the Social Democratic party line upheld by August Bebel and Karl Kautsky, though she had so far worked together with them against the spread of Bernstein's revisionism. She and Karl Liebknecht (*q.v.*) became the leaders of the extreme left wing of the party and found themselves opposed by a united front of all the other groups within the party—by Bebel and Kautsky no less than by Bernstein. Rosa Luxemburg believed that both the "strategy of exhaustion" (Kautsky) advocated by the heads of the party organization and the cautious attitude of the trade union leaders concealed a disinclination to run any serious risks and thus condemned the Social Democrats to fruitless inactivity.

The quarrel within the party flared up openly over the question of political mass strike. This question became a matter of urgency in 1905, in view of the events in Russia. Rosa Luxemburg maintained from the start that action could not be limited to parliamentary measures alone; and her book *Massenstreik, Partei und Gewerkschaften* (1906) was an attempt to draw profitable conclusions for the German workers from the Russian people's experiences. She called the political strike "the living pulse beat of the revolution and likewise its most powerful driving force." She stressed again and again "the element of spontaneity" as a decisive precondition for such a mass strike, and the Bolsheviks reproached her for propagating a one-sided "theory of spontaneity." This contains an element of truth in so far as she gave more weight to the unorganized proletarian masses than did Lenin, who regarded the party, organized in cells, as the most important instrument of revolution. Her view of the nature of proletarian democracy did not accord with Lenin's ideas: after the split in the Russian Social Democratic party (1903) she had denounced the excessively centralized structure of the Bolshevik party and the supposed "Blanquism" of Lenin himself; and her criticism of the Bolshevik terror after the Russian Revolution of 1917 (in her book *Die russische Revolution*, written in prison in the autumn of 1918 and published by Paul Levi in 1922 from a faulty copy) was to proceed on the same lines. She held, in contrast to Lenin, that "the dictatorship of the proletariat consists in the application of democracy, not in its abolition."

In the autumn of 1914, after the outbreak of World War I, the extreme left wing split itself off from the Social Democratic party to form the *Spartakusbund* or Spartacus league, over whose subsequent attitude Rosa Luxemburg exercised great influence, though she was in prison from Feb. 1915 to Jan. 1916 and from July 1916 to Nov. 1918. She gave to the *Spartakusbund* its theoretical basis in the pamphlet *Die Krise der Sozialdemokratie*, published in 1916 under the pseudonym Junius; and she took part in the political quarrels of the day through numerous articles smuggled out of prison and published in the illegal *Spartakusbriefe*. Set free when revolution had broken out in Germany, she drafted the program accepted by the Communist party of

Germany, into which the *Spartakusbund* was transformed at the party congress held from Dec. 30, 1918 to Jan. 1, 1919. Two weeks later, on Jan. 15, Rosa Luxemburg and Karl Liebknecht were arrested and murdered in Berlin by Volunteer officers, members of a *Freikorps* (see GERMANY: History).

It is impossible to evaluate what Rosa Luxemburg's death meant for the future development of German Communism: a Communist party led by her would hardly have become the spineless instrument of the Third International in Moscow.

See P. Frölich, *Rosa Luxemburg: Her Life and Work*, Eng. trans. (1940; 2nd ed. of German original, 1949); J. P. Netti, *Rosa Luxemburg* (E. MA.) 2 vol. (1966).

LUXEUIL, a thermal centre since Roman times, was famous for its abbey (founded c. 590), the greatest of the three houses established in Burgundy by St. Columban through the liberality of Sigebert, king of Austrasia and Burgundy. It was for a time the centre of Irish monasticism on the continent and followed a rule of absolute poverty and renunciation and very strict discipline. The third abbot, Walbert (629–c. 670), adopted Benedictine usages to fill the gaps in the rule of St. Columban and mitigate its severity, and from that time the most interesting feature of the monasticism of Luxeuil was its mixed Columban-Benedictine rule. In its early days it had a renowned scriptorium and a fine library; the most famous manuscript is the late 7th-century lectionary of Luxeuil (now in the Bibliothèque Nationale, Paris). After being sacked by the Saracens (c. 732) the abbey was restored by Charlemagne. Its final suppression came in 1790.

The modern town of Luxeuil-les-Bains (pop. [1962] 8,158), about 20 mi. N.E. of Vesoul, in addition to its mineral springs is noted for fine lace. The remains of the abbey include a 13th to 14th-century church and 16th-century palace, and there are several secular buildings of the 15th and 16th centuries.

See M. Dubois, *S. Columban* (1950). (M. M. Ca.)

LUXOR (in Arabic AL UQSUR or EL AKSUR, meaning "the castles" or "palaces"), a town of upper Egypt in Qina *muhafaza* (governorate) on the east bank of the Nile in a broadening of the valley, 450 mi. above Cairo by river and 418 mi. by rail. Pop. (1957) 32,246. It is the modern town standing with Al Karnak village amid the antiquities of Thebes (*q.v.*) and the centre for visitors to the ruins, having hotels, Anglican and Roman Catholic churches and a hospital. The manufacture of copies of Theban antiquities is an important occupation. (A. B. M.)

LUXORIUS (fl. 5th/6th century), writer of Latin epigrams in the classical tradition, lived in north Africa and seems to have been a Christian, but little further is known of his life. His poems are preserved in the *Anthologia Latina*. There is a group of 86 epigrams in various metres on a number of themes, including works of art and erotic subjects. He also compiled a Virgilian cento in the form of an epithalamium. It is not certain, however, if he is the author of 42 elegiac couplets on mythological characters in each of which the first three words are the same as the last three.

See *Anthologia Latina* ed. by A. Riese, vol. 1 (1894), in the Teubner series, and Pauly-Wissowa, *Real-Encyclopädie der classischen Altertums wissenschaft*, vol. 13 (1927).

LUXURY. The word luxury implies a relatively large consumption of wealth for nonessential pleasures. But there is no absolute definition of luxury, for the conception is relative to both time and person. It is a commonplace of history that the luxuries of one generation may become the necessities of a later period; no hard and fast line can be drawn between luxuries, comforts and necessities. The private bath was one of the greatest luxuries of the Roman empire; in the 19th century its use was largely confined to the wealthy; today it may be ranked among the necessities of civilized life. Looked at from one important standpoint, luxury might be defined as any expenditure in excess of the normal and customary standard of living of the class to which the individual belongs.

The problem of luxury involves economic, social and ethical considerations.

The Economic Aspect.—Luxury has undoubtedly played a great role in the history of economic development. Werner

Sombart in his *Luxus und Kapitalismus* showed that the luxurious expenditure of the papacy and of the courts in the middle ages stimulated the growth of modern capitalism. The rentals of distant estates were concentrated at some central spot; wealth was accumulated there; a relatively large market was created for the products of certain industries and the necessary conditions for the development of capitalist enterprise were fulfilled.

In France, the classic land of luxury, the continual drain of wealth from the countryside to Paris and Versailles was combined with a vicious system of taxation and the burdensome restrictions of feudal tenure. These conditions produced, on the one hand, a considerable amount of industrial activity carefully fostered by the mercantilist policy of the statesman Jean Colbert and his successors; but, on the other hand, they led eventually to the disruption of the old social order amid the turmoil of the French Revolution. It is one of the paradoxes of history that a precisely opposite view and method of life—that of the Puritans, with their strong moral condemnation of luxury and their emphasis on the value of hard work and abstinence from all unnecessary consumption—should have contributed even more notably to the growth of capital and to the expansion of industry and commerce in other countries.

In other directions, also, luxury has made its influence felt. Thus in Italy the rise of the merchant princes gave a new direction to the whole course of art, for the medieval church ceased to be the chief patron of the artist, who now had to conform in his work to the standards and tastes of those who provided the market for his products. The simple piety of the primitives gave place to the sumptuous paganism of the Renaissance period, and that in turn to the elaborate ornamentation and decorative inventiveness which was perhaps at its best in the metal work of Benvenuto Cellini, until at length the over-refinements of a decadent social life killed all artistic inspiration.

Luxury is the inevitable concomitant of the growth of wealth, which brings with it the increase and the differentiation of wants. The fact that the fundamental needs of mankind for a minimum of food, clothing and protection from the weather are relatively soon satisfied gives rise to a demand for greater variety and finer qualities as soon as income rises above the bare subsistence level. This demand, which is especially strong among the feminine portion of the human race, has, in the past, been a great stimulus to economic progress for it has provided an enormously strong incentive to work and effort.

The attitude of the great majority of people toward the luxurious expenditure of the rich is a mixture of envy, sometimes accompanied by, but often devoid of a feeling of resentment; and of approval based on popular economic reasoning. It is a very widespread belief that such expenditure is good for trade because it makes money circulate and therefore increases employment. The classical economists, down to and including Alfred Marshall, had no hesitation in declaring that this reasoning was based on a fallacy. They agreed that the maintenance of racing stables or private yachts, the purchase of magnificent furs or jewelry, does give employment to those engaged in the trades concerned, and that the localities in which these trades are situated benefit from such expenditure. But they argued that the fallacy of such reasoning lay in ignoring the fact that the aggregate real resources of producing power in a country are limited at any one time. A large amount of capital and labour is required to make and equip yachts and racing stables, and this capital and labour is withdrawn from other uses to which it would be put. If the wealth consumed extravagantly were saved and invested, the volume of capital would be increased, the rate of interest would tend to fall and there would be a larger demand for labour to produce goods consumed by other sections of the community. If, in a capitalist society, there was a sudden change in the standards of expenditure of the wealthy classes such that all expenditure commonly recognized as luxurious was regarded with strong social disapprobation, these persons would find themselves impelled to save on a much larger scale than formerly, and a great deal more capital would be available for production. But as the ultimate aim of production is consumption the net effect of the change of policy in regard to

expenditure would be to transfer additional spending power to all the less wealthy members of the community. The latter would benefit by higher money wages, because of the greater demand for their services, and from the still higher real wages, because of the fall in the rate of interest and the larger production of the type of commodities that they consume. Some proportion of this increased wealth would be consumed by the poorer classes in the form of luxuries, as we have defined this term above, or in an increased enjoyment of leisure. The ultimate consequences of such a change would depend upon the economic and social effects of this transfer of real income to the poorer classes and upon the willingness of the wealthier classes to continue to work as hard and efficiently as formerly to produce incomes which they do not themselves enjoy by consumption, and the spending power of which they in fact transfer to other people. The classical view of the economic effects of luxurious expenditure was accepted thus far. Later, however, and particularly under the influence of the ideas put forward by the economist Lord Keynes, a fresh turn was given to the discussion.

When closely examined the classical view is found to depend for its validity upon the assumption of full employment of the community's available resources. If there are idle resources and if the saving portion of the community prefer to hold their savings in the form of money rather than in the form of investing them in some income-yielding use (other than the purchase of old securities), then any additional expenditure on the part of any section of the community will increase the volume of employment and make the total national income larger than it would otherwise have been.

While it is true, on the one hand, that the country as a whole cannot save what it cannot invest, any given level of investment and saving may fall short of occupying fully all the resources of the economy. Under these conditions a decision by an individual to save rather than to spend part of his income may merely have the effect of inflicting an equivalent loss on other individuals. The saver will, it is true, hold a larger command over the community's wealth than before, whether in the form of money, or in the form of securities which have had to be sold by other members of the community in order to finance their losses, but the total savings of the community have not been increased, they have diminished, because of the resultant fall in the national output and income. It still remains true that the community will normally benefit more by an expansion of investment than by an increase of luxurious expenditure, but if the savings would otherwise run to waste in an increase of hoarding, then a rise in what is called the "propensity to consume" will increase the total volume of employment and output, and will not, as in the classical case, be at the expense of an equivalent amount of investment which would otherwise have been made. In this way the popular argument has partially come into its own again in relation to short period analysis and to certain phases of the business cycle when there is a shortage of effective demand.

The Social Aspect.—As T. B. Veblen showed in his *Theory of the Leisure Class* the evils of bad standards of expenditure are not confined to the wealthy classes from which they spring; they propagate and perpetuate themselves by example and imitation right down the social scale from top to bottom; what is called snobbishness is a very potent social force, and it is one which can work for the good as well as for the harm of humanity. It has been well said that mankind is nowhere more vulgar than in the way in which it spends its income.

No amount of time, effort or thought is grudged to the acquiring of wealth, but when we come to consume it we dissipate the fruits of our labours often with small gain to ourselves and with unforeseen and undesired repercussions on the welfare of the community as a whole. What Richard Henry Tawney termed *The Acquisitive Society* (see *Bibliography*) is the outcome of false social values inspired by the all-pervading impulse to acquire riches to the elimination, or at least repression, of other higher ideals. While the churches wrangled over doctrine, they largely ignored the great problem of the art of spending which had become so large a part of the art of living.

The Moral Aspect.—Moralists of all ages have attacked luxury on ethical grounds: the Stoics, because it ran counter to their ideals of simplicity of life; the early Christian Fathers, because they exalted asceticism and poverty into an ideal; the Puritans, because they feared lest the distractions and temptations of luxury might imperil the immortal soul and endanger its chances of salvation; the socialists, because they hold unnatural and immoral the co-existence of luxury on the one side and poverty on the other.

In later times the tendency was increasingly for the moral judgment of luxury to be associated with the general problem of the unequal distribution of wealth—a view which, as is pointed out above, overlooks the fact that luxury is not confined to the richer sections of the community. The rigid condemnation of all luxury on moral grounds is untenable, if only for the reasons that there is no absolute measuring rod by means of which the ultimate social ethical value of expenditure can be tested, and that economic progress and changing standards of life so quickly alter contemporary notions of the types of expenditure that may be included under the category of luxuries. However, a great deal of luxury is undoubtedly a waste of life, not only because of the ill effects it may have upon the individuals themselves, but also because the resulting satisfaction is frequently out of all proportion to the expenditure. As Arthur Cecil Pigou pointed out in his *Economics of Welfare*: "It is at least arguable, that, after a point, as growing wealth gives a man command over more and more luxuries the satisfaction that he gains from each one is, as it were, taken out of relaxed interest in the others, so that the satisfaction which he derives on the whole is not substantially increased." Consumption has its ethical as well as its economic aspects and there are heavy moral responsibilities involved in the exercise by the individual of his right of disposal over the wealth which economic forces and social laws have placed in his hands.

LUXURY TAX, a tax on commodities or services that are considered to be luxuries rather than necessities. Modern examples are taxes levied on the purchase of jewelry, perfume and tobacco.

Great Britain.—In the late 18th and early 19th centuries, taxes were levied in England on carriages and manservants in order to secure revenue from the rich. Such taxes contrasted with those on corn, sugar and timber, which also fell on the poor, often calamitously. While the development of a progressive income tax has modified the whole fiscal structure, luxury taxes on certain commodities, like perfume and furs, have remained.

There are three problems relating to luxury taxes. First, they may lead to a heavy fall in demand and to a reduction in revenue. The English window tax (1695-1851) reduced the number of windows considerably. Against the background of a progressive tax system, a second problem arises even where demand is inelastic. High luxury taxation reduces the volume of private savings and consequently may increase the amount of taxation required for adequate revenue. The third problem concerns the definition of "luxury." (See *Luxury*.) Clergymen and doctors complained persistently in the 19th century that carriages were "bona fide articles required for the practice of a hard-working profession" and should be exempt from duty. Apart from such burdens on special groups of consumers, experience has shown that the luxuries of today become the necessities of tomorrow. High luxury taxation may inhibit the distribution of commodities which would fall rapidly in cost given greater demand.

The favourite argument used by exponents of luxury taxation has been moral rather than economic. Paternalist governments have imposed luxury taxes to restrict private expenditure in certain directions. In England from the 14th to the 16th centuries

sumptuary legislation was designed to repress the ostentation and extravagance of private persons. (See *SUMPTUARY LAWS*.) In the 19th and 20th centuries, increased taxes have been placed on private expenditure upon alcohol, tobacco, entertainment and automobiles. Such expenditure is superfluous in the sense that a large part of it may be said to be in excess of what is required for economic efficiency and personal well-being, although the expenditure affects large numbers of people. Governments have retained such taxation in free economies because the taxes are easy to collect and yield large sums quickly. The moral argument has been pushed into the background in affluent societies.

In time of war luxury taxation is widely used, when it is often considered necessary to interfere with the consumption pattern. William Pitt introduced a wide range of sales taxes during the Napoleonic Wars, while during World War II similar taxes were levied on a long schedule of commodities. In time of peace, also, there is often pressure to impose luxury taxation for reasons connected with the international balance of payments. One of the motives of medieval sumptuary legislation was the reduction of imports of foreign materials. Similarly during the 18th century laws against the wearing of French lawns and laces were designed partly to protect English manufacturers and partly as a weapon of offense against the French. In the 20th century import-restriction policies have often been associated with luxury taxation.

(A. BRI.)

United States.—Unlike the bold groupings and sharply differentiated rates of the British excise and purchase taxes, the varied rates of U.S. excises reflect no clear-cut classification as to degree of essentiality. Perhaps the closest parallel to the British system is found in the heavy reliance upon liquor and tobacco taxes, an expression of the moralistic conception of luxury taxation. Thus, in the early 1960s these two taxes accounted for about 7% of total tax revenues of the central governments of Canada and the United States, as well as about 9% of the tax revenues of the states.

Such revenue importance could only be achieved by heavy consumption in the face of very high tax rates. For example, in the United States the federal whisky tax in 1963 was \$10.50 per proof gallon, to which most states added \$1 to \$3. Beer was taxed at \$9 per barrel by the federal government, plus \$1 to \$4 in most states. To the federal cigarette tax of 8 cents per pack of 20, most states added 3 to 5 cents, and municipalities in several states added a third tax layer. The Canadian excises on whisky and beer were at much the same levels (plus a 10% federal manufacturers' excise tax), but the cigarette tax was almost double that in the United States.

Apart from commodities whose consumption is thought to be harmful, those which legislators consider nonessential for a "reasonable" or "decent" standard of living or more likely to be bought by the rich than by the poor are often embraced in the concept of luxury taxation. Of about 50 items subject to U.S. excise taxation in the early 1960s few met this dual test. The excises levied (mostly at 10%) on furs, jewelry, leather goods, silverware, cameras and films, admissions, dues and initiation fees and a few other items were widely recognized as taxes on non-necessities. Moreover, consumer studies suggested that these taxes as well as those on new automobiles, electrical appliances, radios, television sets, phonographs, and musical instruments and transportation of persons by air were progressive in their impact, taking a larger proportion of high than of low incomes. Yet even this list includes several items whose designation as luxuries would be challenged by many. The remaining federal excises—on telegraph and telephone communications, gasoline, auto parts, tires and tubes, electric light bulbs, matches, toilet preparations and a few others—fall out of the luxury category entirely.

A different approach to luxury taxation, much less frequently found, seeks to single out the luxury component of spending on a given object rather than taxing specified goods and services as luxuries. One example of this is the Massachusetts 5% tax on restaurant meals of \$1 or more (a dividing line which may have singled out luxury dining in the 1930s when it was enacted, but did not serve this purpose after the post-World War II inflation).

The federal rate differential between watches selling above and below \$65, discontinued in 1954, was another case in point. Difficulties of definition as well as administrative complexity militate against wide use of this approach. If these difficulties could be overcome, luxury components of spending on such basic items as food, clothing, furniture and shelter would become eligible for special taxation.

See also AMUSEMENT TAX; EXCISE TAX; TAXATION.

(W. W. HR.)

LUYNES, CHARLES D'ALBERT, DUC DE (1578–1621),

French statesman, for a few months constable of France, was born on Aug. 5, 1578, the son of Honoré d'Albert, seigneur de Luynes (the lordship of Luynes was in Provence). Keeper of the king's birds from 1611, he won complete ascendancy over the neglected Louis XIII (*q.v.*) and was already a councilor of state and governor of Amboise when he sponsored the plot that led to the murder of the marquis d'Ancre on April 24, 1617, and to the exile of Marie de Médicis (*q.v.*) from Paris. Master of France, he recalled Henry IV's old ministers, took a firm line against the Spaniards in Italy, initiated a *rapprochement* with Savoy and with England and tried by diplomacy to contrive a balance of power between the Habsburgs and the Protestants in Germany and Bohemia (see THIRTY YEARS' WAR). The first attempt at rebellion by Marie de Médicis was stopped by negotiation (April 1619), the second by a victorious campaign (Aug. 1620). The king's army then went southwest (Sept.–Nov. 1620), where Béarn had to be awed into obedience. Personally, meanwhile, Luynes had been married to Marie de Rohan-Montbazon, the future duchesse de Chevreuse (*q.v.*), in Sept. 1617; had had his countship of Maille in Touraine erected into the peerage-duchy of Luynes in Aug. 1619; and had strengthened his power in 1619 by taking the governorship of Picardy. To subdue the long-malcontent Huguenots, he had himself made constable of France (March 31, 1621) and marched southwest again. During the campaign he was even appointed keeper of the seals (August); but his 12-week siege of Montauban had to be raised (Nov. 10), and he died of fever at Louetille, in Guienne, on Dec. 15, 1621. As he had prevented Richelieu (then the ablest partisan of Marie de Médicis) from becoming cardinal in Jan. 1621, Richelieu consistently denigrated him; yet Luynes had foreshadowed the future policy of Richelieu.

See V. Cousin, "Le Duc et connétable de Luynes," 13 articles, *J. des Savants* (1861–63); B. Zeller, *Études . . . le connétable de Luynes . . .* (1879).

LUZÁN CLARAMUNT, IGNACIO DE (1702–1754),

Spanish critic and poet who introduced neoclassical theories into Spain, was born in Saragossa on March 28, 1702, but was brought up and educated in Italy, where he studied under the philosopher Vico and adopted the literary principles of classicism. Returning to Spain in 1733, he published *La Poética o reglas de la poesía en general y de sus principales especies* in 1737. It is based largely on Lodovico Muratori's treatise on poetry, and to a lesser degree on earlier Italian commentators on Aristotle, as well as on Boileau and other French critics. He was elected to the Real Academia, had various government posts and died in Madrid on May 19, 1754. He translated from many languages, and published versions of Greek poets and Milton. Luzán's own poetry is much less important than his criticism.

La Poética is typical of neoclassic literary theory, which Luzán saw as the means of rehabilitating Spanish literature. He severely censured the poetry and especially the drama of the 17th century, which he attacked for having forsaken the classical unities, for a lack of moral sense and for the superficiality of its characters. This criticism proved powerless to produce literary works of appreciable merit, but Luzán's influence was greater than can be measured by the overt failure of the neoclassic formula in Spain, and informs some of the most important writing of the first half of the 19th century.

(J. F. SR.)

LUZERN: see LUCERNE.

LUZON, the main and largest island of the Philippines, located in the northern part of the archipelago. Area 40,420 sq.mi. Most of the island lies north of Manila in a north-south oriented rectangular area; south of Manila lies the volcanic Batangas pen-

insula and extending southeast of this is the long, narrow, irregular Bicol peninsula. The island has extreme dimensions of 460 mi. by 140 mi., and a coast line measuring 2,242 mi. In 1960 it had a population of 13,929,790, or an over-all density of 345 people per square mile. Densities are very high along the northwest coast, in the central plain and many parts of the Bicol peninsula. The east coast and the Sierra Madre mountains have very low population densities; the Mountain province and the Cagayan valley are moderately populated.

The more important mountain ranges are the Cordillera Central in the north, the Sierra Madre following much of the east coast and the Zambales range on the central west coast. Mt. Pulog, 9,606 ft., in the Cordillera Central, is the highest peak. Isolated volcanic cones, as the near perfect Mt. Mayon, 7,943 ft., are found in the Bicol peninsula.

Agriculturally Luzon is the leading island, producing over 65% of the country's rice; the central Luzon plain, stretching for 100 mi. N. of Manila, is the chief centre. On the Bondoc and Bicol peninsulas are found the most extensive coconut plantations in the world; this is a leading area for the export of copra. The southern end of the Bicol peninsula is noted as a producer of abacá while both the Ilocos provinces and the Cagayan valley provide tobacco surpluses. Spectacular rice terraces have been built by the peoples of the Mountain province. Sugar cane is an important cash crop in the Central plain and in Batangas. Manufacturing is largely limited to Manila and suburbs, a notable exception being the modern petroleum refinery at Batangas.

Iron, gold and manganese are mined in the Camarines provinces while Zambales is noted for the production of both chromite and copper. The Cordillera Central produces large amounts of gold and copper and has good pine forests which provide considerable timber for the mining industry. Other forest areas, notably along the east coast, produce excellent hardwoods for cabinet work and the production of quality veneers.

Administratively, the island is divided into 24 provinces, Abra, Albay, Bataan, Batangas, Bulacan, Cagayan, Camarines Norte, Camarines Sur, Cavite, Ilocos Norte, Ilocos Sur, Isabela, Laguna, La Union, Mountain, Nueva Ecija, Nueva Vizcaya, Pampanga, Pangasinan, Quezon, Sorsogon, Tarlac (*qq.v.*), Rizal and Zambales. Its quarried cities include Baguio, Manila, Quezon and San Pablo (*qq.v.*).

For the ethnology and history of Luzon see PHILIPPINES, REPUBLIC OF THE.

(R. E. HE.)

LUZZATTI, LUIGI (1841–1927), Italian economist and statesman who did much to strengthen his country's finances both internally and externally, was born of Jewish parents in Venice on March 1, 1841. After studying law at Padua, he had to go into exile because of his participation in a scheme for establishing a workers' mutual aid society. In 1863 he became economics lecturer at the technical institute in Milan. When Austrian rule in Venetia came to an end he returned to become professor of constitutional law at Padua in 1867. Later he was appointed to chairs at Perugia (1894) and at Rome (1898).

A believer in the co-operative ideas of F. H. Schulze-Delitzsch, Luzzatti worked to realize them in Italy; he contributed to the spread of "people's banks" to provide credit on reasonable terms for those whose small incomes barred them from recourse to the big national banks; and he founded the first co-operative store in Italy (1865). In 1869 Marco Minghetti, minister of agriculture and commerce, appointed Luzzatti secretary general of the ministry of agriculture and commerce. Together they brought about the abolition of government control over commercial companies. Luzzatti entered parliament in 1871 and was continually re-elected until 1921, when he was made a senator.

Theoretically a free trader, Luzzatti yet helped to create the Italian protective system. He compiled the Italian customs tariff in 1878 and took a leading part in the negotiation of the commercial treaties between Italy and other countries. In 1898 he ended the tariff war with France.

Luzzatti was minister of the treasury in four cabinets between 1891 and 1906. During his last term at the treasury he achieved the conversion of the Italian 5% debt (reduced to 4% by the tax)

to 3½%—to be eventually lowered to 3¼%. Though the actual conversion was not completed until after the fall of the cabinet to which he belonged, the project was recognized as his and he was given the title of minister of state for life (1906).

Luzzatti was minister of agriculture and commerce in 1909 and prime minister from March 1910 to March 1911 (see ITALY: History). He died in Rome on March 29, 1927. His memoirs were published in 1931–35.

LUZZATTO, MOSES HAYIM (1707–1747), Italian Jewish cabalist and writer, born in Padua, was one of the founders of modern Hebrew poetry. He wrote lyrics and the drama *Migdal 'Oz* ("Tower of Victory"), but early turned to cabalist studies, claiming to receive heavenly messages and to be the Messiah. After being expelled by the Italian rabbis, who feared a further outbreak like that of Sabbatai Zebi (q.v.), he moved to Amsterdam (1736), where he wrote his morality play *La-Yesharim Tehillah* (Eng. trans., *Praise for Uprightness*, 1915) and an ethical work, *Messilath Yesharim* (Eng. trans., *The Path of the Upright*, 1936), which still ranks as a classic. He died of the plague in Palestine in 1747.

See S. Ginzburg, *The Life and Works of M. H. Luzzatto* (1931).

LUZZATTO, SAMUEL DAVID (1800–1865), Italian Jewish writer and scholar, known from his initials as Shedal, was born in Trieste on Aug. 22, 1800. In 1829 he became professor at the rabbinical college in Padua, where he died on Sept. 30, 1865. In his writings, which are in Hebrew and Italian, he presents an emotional and antiphilosophical concept of Judaism, and his Hebrew poetry is also pervaded by national spirit. His chief merit as a scholar lies in biblical exegesis, Hebrew philology and the history of Hebrew literature. His extensive correspondence in Hebrew was published in 1882–94 and in other languages in 1890. His autobiography in Italian appeared in 1882.

See M. Klotz, *S. D. Luzzatto als Bibelexeget* (1925); S. Morais, *Italian Hebrew Literature* (1926). (S. M. SN.)

LVOV, GEORGI EVGENIEVICH, PRINCE (1861–1925), head of the first Russian provisional government set up during the March Revolution of 1917. He was born at Popovka, near Tula, on Nov. 2 (new style; Oct. 21, old style), 1861, of an old aristocratic family in which he was brought up to have firsthand experience of peasant life. After graduating in law from Moscow university in 1885, he joined the civil service, but resigned in 1893. Fired by a lofty idealism, which he combined with a talent for practical organization, he devoted himself to social work. After serving in the elected council (zemstvo) of Tula he led in organizing voluntary relief work in the far east during the Russo-Japanese War. During World War I, as president of the All-Russian Union of Zemstvos, he performed the same tasks on a more extensive scale and with considerable success, but obstruction from official quarters made him increasingly critical of the tsarist regime. Already in 1906, as a member of the first *duma*, he had been put forward by liberal leaders as a candidate for ministerial office, and his reputation now stood higher than ever. The emperor Nicholas II on the day of his abdication (March 15, 1917) approved Lvov's nomination as prime minister.

Lvov, however, was psychologically unsuited to hold such a responsible post. He had an almost Tolstoyan disdain for the realities of political power and regarded the Revolution through rose-coloured spectacles. In an effort to maintain his popular standing he drifted far to the left. After the "July days" he belatedly realized the need for firmer measures, but being loath to apply them himself resigned in favour of A. F. Kerenski (July 21). In 1918 he emigrated to Paris, where he died on March 6, 1925.

See T. I. Polner, *Zhiznenny put knyazya G. E. Lvova* (1932).

(J. L. H. K.)

LVOV (Ukrainian *Lviv*), an *oblast* in the Ukrainian Soviet Socialist Republic of the U.S.S.R., formed in 1939 after the Soviet occupation of eastern Poland from parts of the Polish provinces of Lwow and Tarnopol (Ternopol). Covering 8,378 sq.mi. it lies in the western Ukraine adjacent to the present Polish frontier and extends from the crest line of the Carpathian mountains in the southwest, across the foothills and the upper Dniester valley, over the Roztoche watershed (the western end of the Volyno-Podolsk

upland) and into the upper basin of the Western Bug. The southern half of the *oblast* was the separate Drohobych *oblast* until May 21, 1959. The varying relief gives rise to great variation in soil and vegetation. The northern half, in the Bug-Prpyat (Pripiet) basin, lies in the southern mixed-forest zone, dominated by oak, hornbeam and other hardwoods on podsol soils, with pine in sandy areas. Much of the forest has been cleared. The upland area round the town of Lvov is forest-steppe on degraded chernozem soils. The Dniester valley has meadows along the river and the original light forest cover has largely been removed. The Carpathian slopes are densely forested, by beech lower down on brown earths, and conifers higher up on podsoles. Summits, which are gently rounded, are in open alpine meadows, called *poloniny*, much used for pasture. The climate is moderately continental (Lvov city has a January average temperature of -4°C . [25°F .] and a July average of 18°C . [64°F .]), but there is a great local variation with relief. Precipitation is fairly high, 24–28 in. a year and rising to 40 in. in the mountains.

The population (1959 census) was 2,107,858. Of these, 837,930 (40%) were urban dwellers, half of them living in the administrative centre of Lvov (410,678). There are in all 35 towns and as many urban districts, all of small size. The rural population is concentrated most densely in the neighbourhood of Lvov and in the Dniester valley. The southern part of the *oblast* has a small but important oil field, centred on Borislav and Truskavets. In association with the field are large deposits of natural gas, which are being developed. Dashava is the main centre for natural gas and from there pipelines run to Lvov, Kiev and as far as Moscow, while a line to Leningrad was under construction in 1961. Potassium salts are also obtained in this area. Manufacturing is chiefly concentrated in Lvov, with Drohobych, Stry and Sambor as minor centres. In the Carpathians timber working is highly developed. Furniture making is widespread and at Zhidachov is the largest paper mill in the Ukraine. All the *oblast*, except the Carpathians, is under intensive agriculture. Rye is the chief crop, followed by wheat, maize (corn) and sugar beet. Stock-breeding, especially of cattle and sheep, is important in the mountains. (R. A. F.)

LVOV (Ukrainian *Lviv*; Polish *Lwow*), a town and *oblast* administrative centre of the Ukrainian Soviet Socialist Republic, U.S.S.R., lies in the western Ukraine on the Roztoche watershed between the Dniester and Western Bug basins, near the source of the Bug, 250 mi. W.S.W. of Kiev. Pop. (1959) 410,678. Founded in 1256 by the Galician prince Danilo (Daniel) Romanovich, the town has always been the chief centre of Galicia (q.v.). Its key strategic position on the great east-west route along the northern flank of the Carpathian mountains, controlling the low passes through the mountains into the Hungarian plain, has given Lvov a stormy history. Captured by the Poles in 1340, it remained in their hands until the first partition of Poland in 1772, when it passed to the Austrian empire and was renamed Lemberg. It returned to Poland in Nov. 1918. In Sept. 1939 the Soviet army occupied Lvov under terms of the Molotov-Ribbentrop treaty. It was later occupied by the Germans, but its possession by the U.S.S.R. was confirmed in 1945, when Lvov was created an *oblast* centre of the Ukraine. Industry has developed rapidly and the town manufactures omnibuses, loading machinery, agricultural implements, bicycles, electric lamps, telecommunications equipment, glass, textiles, foodstuffs, furniture, veneer, cardboard, paints and perfumery. Lvov is excellently served by the nine railways converging on the town (a reflection of its nodal position) which link it to all parts of the Ukraine, to Belorussia, Moldavia, Hungary, Czechoslovakia and Poland.

Lvov has always been an important centre of Ukrainian culture, which flourished there in tsarist times, when Ukrainian national feeling and language were suppressed in the Russian Ukraine. Its cultural significance still remains, and in this respect the city is probably second only to Kiev in the Ukraine. There is the Ivan Franko State university, founded in 1661, 11 other higher educational establishments, 28 special and technical schools and 70 general schools. Lvov has an opera house and five theatres and is a publishing centre. (R. A. F.)

LYALLPUR, a canal-colony town in the Sandal bar (Rechna Doab upland) and headquarters of Lyallpur district in the Sargodha division of West Pakistan. Pop. (1961) 425,248. Named after Sir James Lyall, lieutenant governor of Punjab, it was founded in 1892 as a market town and became the headquarters of the Lower Chenab colony, dependent on irrigation from the Lower Chenab canal. Eight main roads or bazaars radiate from the town's centre, where stands a clock tower, and terminate on the road which encircles the main town. In between the circular road and the clock tower is the Ring road (Gol bazaar), the main wholesale market for cloth, grains and ghee (clarified butter). With the increase in population after independence (1947), several new satellite towns sprang up. Situated in the midst of a cotton and wheat producing area, Lyallpur has grown into an important centre for the textile, hosiery and flour milling industries. Other chief products are vegetable oil, soap and sugar. Lyallpur is an important educational and cultural centre with six colleges affiliated to the University of the Panjab besides many schools. The well-known Panjab agricultural college became a university in 1961. There is a public park known as the Company Bagh and a separate enclosed park for women.

LYALLPUR DISTRICT was formed in 1904 of the lands in the Rechna Doab, carved out of the neighbouring districts of Jhang, Sheikhupura, Montgomery and Multan. Area 3,516 sq.mi.; pop. (1961) 2,683,838. It consists of a fertile plain, irrigated by the Lower Chenab canal. Cotton, wheat and sugar cane are the chief crops. Formerly in Multan division it now forms part of the new Sargodha division. (K. S. Ad.)

LYAUTEY, LOUIS HUBERT GONZALVE (1854-1934), French marshal, a firm believer in the civilizing virtue of colonialism and the real builder of the protectorate over Morocco, was born at Nancy on Nov. 17, 1854. As a child he suffered a spinal injury but nevertheless did well at school and entered St. Cyr in 1873. The routine there disappointed him, but an army officer, Albert de Mun, aroused his enthusiasm for social reform; and by the time of his entry into the Staff college he was already helping the Catholic workingmen's clubs.

After service with a cavalry regiment at Châteaudun and six months' sick leave, Lyautey went to Algeria in 1880. He returned to France in 1882 and was made captain the next year. He expressed his royalist convictions to the comte de Chambord on a visit to Austria and was profoundly distressed when Pope Leo XIII, at an interview in Rome, showed himself well disposed to the French republican regime. As a strong Legitimist, however, he felt no sympathy for the Orleanists and so became readier to serve the republic after the comte de Chambord's death (Aug. 1883).

In command of a corps at St. Germain (1887), Lyautey paid special attention to his men's welfare. He also made a name for himself in literary circles and wrote an article for the *Revue des Deux Mondes* on the social role of the officer under universal military service; but after further posts at Gray and at Meaux, he found himself longing for action.

In Aug. 1894 Lyautey was sent to Indochina. At Tongking he met Joseph Galliéni, whose idea of conquest as a means of civilization he adopted and from whose experience he profited. When Galliéni summoned him to Madagascar, Lyautey went immediately, despite his liking for Tongking. With the rank of lieutenant colonel, he was given the task of pacifying one-third of the island. Colonel and commander of the forces in the south in 1900, Lyautey took only two years to conquer all that area.

Lyautey returned to France in 1902 and took command of the 14th hussars at Alençon. Then, in 1904, Célestin Jonnart, governor general of Algeria, obtained for him the post of commandant of the subdivision of Ain-Sefra. Now general of brigade, Lyautey did not hesitate to encroach on Moroccan territory in order to round the frontier off. Jonnart protected him when Morocco protested to France, and Lyautey reduced the frontier tribes to obedience. Commandant of Oran from 1906, he continued insidiously pushing the frontier westward.

At the end of 1910 Lyautey was recalled to France to be commandant of the army corps at Rennes; but in April 1912 he was appointed resident general in Morocco, over which the French pro-

tectorate had just been proclaimed. Besieged in Fès by insurgent tribes, he extricated himself and then replaced the sultan Maulay Hafid by his more reliable brother Maulay Yusuf. He had now before him the task of conquering and pacifying the whole country; and in this he showed respect for local institutions. He had a sense of grandeur that appealed to the Arabs and showed disengagement in his choice of assistants.

In July 1914, on the eve of World War I, the French government ordered Lyautey to withdraw from the interior of Morocco to the ports and thus release numbers of the occupying troops for service in France. Though he at once sent home the forces required of him, he yet was able to hold the whole country. Recalled to France to be minister of war (Dec. 1916-17), he then returned to Morocco. A member of the Académie Française from 1912, he was made a marshal of France in 1921.

Lyautey's achievement in Morocco was characterized by vitality and realism, but yet resulted in an "aristocratic" type of colonization. His reliance on the traditional structure of the administration and on Islam tended to preserve the old Morocco, while his imaginative policy of exploiting the country's economic resources, building roads and towns and developing the port of Casablanca was creating a new Morocco in contradiction with it.

After a long sick leave in 1923, Lyautey thought of leaving Morocco in 1924, when the parties of the left won the elections in France. Staying to face the revolt of Abd-el-Krim, he received little consideration from Marshal Pétain, whom Paul Painlevé's government sent out to command operations; and on Sept. 24, 1925, he resigned. Thereafter he lived at Thorey (Meurthe-et-Moselle), concerning himself with work for young people. His last public service was to organize the Colonial exhibition of 1931. Lyautey died at Thorey on July 21, 1934.

LYCANTHROPY, a psychiatric state in which the patient believes he is a wolf or some other nonhuman animal (Gr. *lykos* "wolf" + *anthropos* "man"). Undoubtedly stimulated by the once widespread superstition that lycanthropy is a supernatural condition in which men actually assume the physical form of other animals, the delusion has been most likely to occur among people who believe in reincarnation and the transmigration of souls (see METEMPSYCHOSIS). Usually a person is deemed to take the form of the most dangerous beast of prey of the region: the wolf or bear in Europe and northern Asia, the hyena or leopard in Africa and the tiger in India, China, Japan and elsewhere in Asia; but other animals are mentioned too. Both the superstition and the psychiatric disorder are linked with belief in animal guardian spirits, vampires, totemism, witches and werewolves. The folklore, fairy tales and legends of many nations and peoples show evidence of lycanthropic belief.

Stories of men turning into beasts go back to antiquity. In parts of ancient Greece werewolf myths, presumably stemming from prehistoric times, became linked with the Olympian religion. In Arcadia, a region plagued by wolves, there was a cult of the Wolf-Zeus. Mt. Lycaeus was the scene of a yearly gathering at which the priests were said to prepare a sacrificial feast that included meat mixed with human parts. According to legend, whoever tasted it became a wolf, and could not turn back into a man unless he abstained from human flesh for nine years (see LYCAON).

The Romans also knew this superstition. Anyone who was supposed to have been turned into a wolf by means of magic spells or herbs was called *versipellis* ("turnskin") by the Romans.

Stories about the werewolf (in French, *loup garou*) were widely believed in Europe during the middle ages. Outlaws and bandits played on these superstitions by sometimes wearing wolfskins over their armour. At that time people were unusually prone to develop the delusion that they themselves were wolves; suspected lycanthropists were burned alive if convicted. Only rarely was their condition recognized as a psychological disturbance. Although the superstition no longer is common in the 1960s, traces still linger. See also WITCHCRAFT.

LYCAON, a mythical king of Arcadia. At Mt. Lycaeus a very extraordinary ceremony, the Lycaea, in honour of Zeus Lycaeus took place; it is alleged (Plato, *Republic*, viii) that a man was sacrificed and his entrails put with those of more usual victims; that anyone who tasted them became a wolf (*lykos*); later authors add that the man thus transformed belonged to a particular clan, and that he remained a wolf for nine years (a sacred number), after which he might become a man once more if in that time he had not tasted human flesh again. The whole story is suggestive of the Lion and Leopard societies of Africa.

In explanation the following story was told (Ovid, *Metamorphoses*, i, 209-243): Lycaon, in early days, was an impious and cruel king. Having occasion to entertain Zeus, he, or his sons, set before the god human flesh (in some versions, the flesh of Lycaon's own son, Nyctimus). The god was not deceived, and in wrath caused the deluge which in Deucalion's time devastated the earth (see DEUCALION). It has been suggested that behind the figure of Lycaon is concealed some ancient local god, afterward identified with Zeus; the theory is in no way impossible, but it leads little further, since there is no agreement as to the nature of the supposed god. See also LYCANTHROPY.

LYCAONIA, an ancient region in the interior of Asia Minor, north of the Taurus mountains, corresponding to the south central part of modern Turkey, bounded on the east by Cappadocia, on the north by Galatia, on the west by Phrygia and Pisidia, and on the south by Cilicia Tracheia. Iconium (Konya), which according to Xenophon was the last city of Phrygia visited by Cyrus on his eastward march, became chief city of Lycaonia in Seleucid times, and capital of the tetarchy of Lycaonia in the 1st century B.C. In the 1st century A.D. the Roman administration distinguished between the eastern part of Lycaonia, which was governed by King Antiochus IV, and that part which formed a region of the province of Galatia. The words of Acts xiv, 6, where Paul is said to have fled from Iconium "to Lystra and Derbe, cities of Lycaonia," imply that while Iconium was considered to be in the Phrygian region of the province of Galatia, Lystra and Derbe lay in the Lycaonian region of that province.

Lycaonia is described by Strabo as a cold region of high plains, affording pasture to wild asses and to sheep. Amyntas, king of Galatia, to whom the district was for a time subject, maintained there not less than 300 flocks. It forms part of the interior tableland of Asia Minor, and has an elevation of more than 3,000 ft. The plain is interrupted by some minor groups of mountains, of volcanic character, of which the Kara Dag in the south rises above 7,000 ft. Experiencing great extremes of temperature and only a moderate rainfall, it is still largely ranching country. But extensive irrigation works have rendered fertile districts near Konya and Eregli, where both surface and subterranean water seeps down from the Taurus range.

The Lycaonians were to a great extent independent of the Persian empire, and were, like their neighbours, the Isaurians, wild and lawless freebooters; but their country was traversed by one of the great high roads through Asia Minor, from Ephesus to the Cilician Gates, and a few considerable towns grew up along or near this line, notably Iconium, Laodicea Combusta (Ladik) and Laranda (Karaman). Derbe and Lystra, which appear from the Acts of the Apostles to have been considerable towns, were between Iconium and Laranda, Lystra being about 1 mi. N.W. of modern Hatunsaray; the site of Derbe is disputed. Lycaonia was Christianized very early, and its ecclesiastical system was more com-

pletely organized during the 4th century than that of any other region of Asia Minor. Its administration and grouping changed often under the Romans, and in the early Christian era it was largely included in the province of Galatia; St. Paul's Epistle to the Galatians was, in the opinion of some scholars, addressed to the churches of southern Lycaonia. About A.D. 371 Lycaonia was formed into a separate province.

The Lycaonians appear to have retained a distinct nationality in the time of Strabo, and were probably one of the aboriginal peoples of Asia Minor. The mention of the Lycaonian language in the Acts of the Apostles (xiv, 11) shows that the native language was spoken by the common people at Lystra as late as A.D. 50.

(Wm. C. B.)

LYCÉE (FRANCE), a state-maintained secondary school in the French educational system; municipally maintained secondary schools are known as *collèges*. See SECONDARY EDUCATION; EDUCATION, HISTORY OF; FRANCE: *Administration and Social Conditions: Education*.

LYCEUMS AND CHAUTAUQUAS. The first lyceum in the United States was founded in 1826 in Millbury, Mass., by Josiah Holbrook, a teacher and lecturer. Named from the place where Aristotle lectured to the youth of ancient Greece, the lyceums were voluntary local associations that gave the people an opportunity to hear debates and lectures on topics of current interest. Thus they constituted an early form of organized adult education in the United States. The lyceums multiplied rapidly after 1826, chiefly in New England, New York and the middle west. By 1834 there were nearly 3,000 local groups, many of which were organized in a national association known as the American Lyceum. One of the major topics discussed at lyceum meetings in the early years was the establishment of public schools.

At first the lyceums were local ventures with speakers supplied by the community. By 1840 the lyceums had become professionalized institutions with outside lecturers to whom fees were paid. Among the well-known speakers who traveled from state to state addressing local lyceums were Ralph Waldo Emerson, Henry David Thoreau, Daniel Webster, Henry Ward Beecher, Nathaniel Hawthorne and Susan B. Anthony. A number of Emerson's essays were originally written as lyceum lectures. The local lyceums continued to flourish until the Civil War. Musicians, elocutionists, readers and other entertainers were added to the lyceum programs. After the Civil War the lyceum movement came under the management of bureaus founded as commercial enterprises. One of the largest of these organizations was the Boston Lyceum bureau later known as the Redpath Lyceum Bureau, founded in 1868 by James Redpath.

A parallel movement arose after the Civil War in the chautauqua, which originated at Fair Point on Chautauqua lake in New York state. In 1874 the Rev. John H. Vincent, aided by Lewis Miller of Akron, O., organized an assembly for the training of Sunday school teachers and church workers at Fair Point. This first assembly developed into an annual affair, and the name of the meeting place was known after 1876 as Chautauqua. At first the annual assemblies were entirely religious in nature, but gradually the program was broadened to include general education and popular entertainments. In the beginning the Chautauqua programs were organized to enable teachers and church workers to advance their education during the summer vacation months. In later years the summer lectures and classes were supplemented by a program of directed home reading and correspondence study. William Rainey Harper, later president of The University of Chicago, became educational director in 1883 and attracted outstanding speakers. By 1900 the Chautauqua assembly included a school of theology, a correspondence school and a publishing house. William Jennings Bryan went there year after year to deliver his "Cross of Gold" speech. Tents were used for many years to house the people who attended the annual sessions, but by 1900 a number of hotels and permanent homes had been constructed. Dramatic performances were frowned upon until 1911 when Shakespearean plays were performed for the first time.

The success of the Chautauqua, N.Y., assembly led to the founding of many "chautauquas" throughout the United States pat-

termed after the original institution. By 1900 there were over 400 such local assemblies. The lyceum booking agents entered the chautauqua field, supplying the lecturers and musicians who traveled from one community to another. In the peak year of 1924 the traveling chautauquas visited approximately 10,000 communities and were attended by over 40,000,000 persons.

The circuit chautauquas declined after 1925, and by 1932 less than 300 U.S. communities were visited by them. The decline of the chautauqua has been attributed to: (1) motion pictures and radio, which supplied competing entertainment; (2) automobile transportation, which enabled people to travel to larger centres; (3) the greater sophistication of the public; and (4) the service and luncheon clubs, women's clubs and similar groups that absorbed the time and interest formerly devoted to the chautauqua. The original institution at Chautauqua remained in existence, however, offering a diversified program that included symphony concerts, operas, plays, university summer school courses and outstanding lecturers.

LYCHNIS, a genus of plants of the pink family (Caryophyllaceae; *q.v.*), including numerous species, several of which are cultivated and are called campion or catchfly. The Maltese cross (*L. chalcedonica*), three feet high, has dense heads of bright scarlet flowers, both single and double. The crown campion (*L. coronata*), one to two feet high, has clusters of scarlet, crimson, pink and white flowers.

Other garden species are *L. fulgens* and *L. haageana*. *L. flos-cuculi* is the ragged robin or cuckoo flower. Several species are native to western North America, including *L. drummondii*, found from Manitoba to Nebraska and west to the Pacific coast. All are hardy herbaceous perennials.

LYCIA, an ancient district in southwestern Asia Minor, occupying the coast between Caria and Pamphylia, and extending inland as far as the ridge of Mt. Taurus. At present, most of Lycia forms part of the Turkish *il* of Antalya. It is a rugged, mountainous country and the coast is indented by a succession of bays, the most marked of which is the Gulf of Fethiye in the extreme west. A number of smaller bays and broken, rocky headlands, with a few small islets, constitute the coastline thence to the southeast promontory of Lycia, modern Gelidonya Burnu. Though the mountain ranges of Lycia are all offshoots of Mt. Taurus, in ancient times several of them were distinguished by separate names. Such were Daedala in the west, adjoining the Gulf of Fethiye; Cragus on the seacoast, west of the valley of the Xanthus; Massicytus (10,000 ft.), nearly in the centre of the region; and Solyma in the extreme east above Phaselis (7,800 ft.). The steep and rugged pass between Solyma and the sea, called the Climax ("ladder"), was the only direct communication between Lycia and Pamphylia. The only considerable rivers are the Xanthus, which descends from the central mass of Mt. Taurus, and flows through a narrow valley till it reaches the city of Xanthus, below which it forms a plain of some extent before reaching the sea, and the Limyrus, which flows into the Gulf of Finike. The small alluvial plains at the mouths of these rivers are the only level ground in Lycia, but the hills that rise thence toward the mountains are covered with thick scrub and pine forests. The upper valleys and mountainsides afford good pasture for sheep, and the main Taurus range encloses several extensive upland basin-shaped valleys (*yailas*). (See ASIA MINOR.)

According to Artemidorus (c. 100 B.C.), 23 towns made up the Lycian league; but Pliny states that Lycia once possessed 70 towns, of which only 26 remained in his day (1st century A.D.). Recent researches have confirmed that the coast and the valleys were studded with towns. On the Gulf of Fethiye stood Telmessus, while a short distance inland were the small towns of Daedala and Cadyanda. At the entrance of the valley of the Xanthus were Patara, Xanthus (*q.v.*) itself, and, a little higher up, Pinara on the west and Tlos on the east side of the valley. Myra (*q.v.*), one of the most important cities of Lycia, occupied the entrance

of the Andriacus valley; on the coast between this and the mouth of the Xanthus stood Antiphellus, while in the interior, at a short distance, were Phellus, Cyaneae and Candyba. In the alluvial plain formed by the Arycandus and Limyrus rivers stood Limyra. Arycanda commanded the upper Arycandus valley. On the east coast stood Olympus, one of the cities of the league, while Phaselis, a little farther north, which was a much more important place, never belonged to the Lycian league and appears always to have been independent.

History.—According to Greek tradition, apparently derived from Hecataeus (c. 500 B.C.), the builders of the monumental walls and galleries of Tiryns had been Cyclopes from Lycia, sent together with an army by the king of the Lycians to secure Tiryns for his daughter, several generations before the Trojan War. This queen also appears in the story of Bellerophon (*q.v.*), who was sent from Tiryns to Lycia bearing a letter containing the "sinister script." The story is told in Homer's *Iliad*, where the Lycian army and its leaders Glaucus and Sarpedon play a prominent part in the Trojan War.

These early Lycians are frequently mentioned in Egyptian, Hittite and Ugaritic records of the 14th and 13th centuries B.C. According to the Amarna tablets the Lycian fleet conducted yearly raids on Cyprus; in the inscription of Ramses II the Lycians form an important part of the Hittite army at the battle of Kadesh; the archives of Ugarit indicate Lycian sea raiders, while one record says the whole Ugaritic fleet is off the Lycian coast. The Hittite documents show the Lycians well established on the west coast of Asia Minor and name a number of Lycian cities situated between the Hittite power and the encroaching Achaeans (Ahhiyawa; see HITTITES: *History*). The Lycians are described as Hittite vassals, but their cities often seem to contain pro-Achaean factions and are governed not by kings but by city elders. The role played by the Lycians in the final collapse of the Hittite empire is uncertain.

When written records appear again in the Aegean area, the Greeks have strung their colonies along the west coast of Asia Minor, and the Lycians are confined to Lycia proper. Both Phrygians and Lydians failed to subdue Lycia, but after the fall of the Lydian kingdom under Croesus (c. 546 B.C.) the Lycian cities were conquered by Harpagus, the general of Cyrus, after a heroic resistance described by Herodotus. But while acknowledging the suzerainty of Persia, the Lycians contrived to remain practically independent and for a time even joined the Delian league. They were later incorporated into the empire of Alexander the Great. Even after their conquest by the Romans, however, they enjoyed a relative freedom and preserved their federal institutions as late as the time of Augustus. Under Claudius, Lycia was annexed (A.D. 43) to the Roman empire and united with Pamphylia as a province; it became a separate province in the 4th century.

Archaeology.—Numerous large mounds (*höyük*) on the high plateau of inner Lycia reveal a settled population early in the Bronze Age. They are offshoots of cultures farther north, decreasing and disappearing when within reach of the coast. American excavations at Elmali began in 1963. The coastal areas of Lycia were not settled in the Bronze Age, as shown by excavations at Xanthus and Antiphellus. The occupation of the country by the Lycians is of somewhat later date and, since the Lycian inscriptions are not found far inland, it may be concluded that they entered the country from the sea. The alphabet of Lycia was derived from the Doric alphabet of Rhodes, with an admixture of Anatolian characters, some of which seem to have retained their syllabic values. The Lycian language has now been proved beyond doubt to belong to the Luvian group. (See ANATOLIAN LANGUAGES.)

Monuments discovered in Lycia during the 19th century were transported to the British museum; and include examples of a very distinct native architecture. Its characteristic features are displayed in the various types of sepulchral structures, such as the pillar-tombs where the burial chamber is at the top of a tall, square tower; surrounded by reliefs, or the large sarcophagi with pointed arches, often sculptured and, like many façades of rock-

cut tombs, closely imitating wooden structures. This is indeed the most striking aspect of Lycia: the innumerable tombs and funerary monuments strewn over the whole countryside, particularly in the coastal areas, and always placed in conspicuous positions. But the temples and theatres found in almost every town, some of them very large, are sufficient to attest the influence of Greek civilization; and this is confirmed by the sculptures which are for the most part Greek in style.

Among the distinctive social customs of the Lycians, as described by Herodotus and confirmed by evidence from inscriptions, is their stress on matrilineal descent and the special status of the sister's son. Their political institutions are based on federal organization. The focal points of their religion were the cults of Apollo and Artemis, whose birthplace was considered to be the Letoon, between Xanthus and Patara. French excavations began in 1950 at Xanthus and in 1963 at the Letoon.

LYCOPHRON (3rd century B.C.), of Chalcis in Euboea, Greek poet and scholar, is best known because of the attribution to him of the extant poem *Alexandra*. He was invited to work on the comedies in the Alexandrian library (c. 285 B.C.) and wrote a treatise on comedy. He also wrote numerous tragedies, of which only a few fragments survive. The *Alexandra* is in form a messenger's speech in tragic iambs in which the prophecies of Cassandra are reported. The poem carries the cult of erudition and obscurity to extremes; the material is recondite; the vocabulary is exotic; the style is affected; and the names of gods and men are disguised by cult-title or riddling periphrasis. Considerable historical interest attaches to the references to Rome and the West, which have been thought to be more in keeping with the historical situation in 197 B.C. than with that a century earlier. On this ground it has been forcibly argued that the *Alexandra* is by a later author than the tragedian Lycophron.

See edition with Eng. trans. by A. W. Mair, *Callimachus and Lycophron* (1921), in the "Loeb Series." See also K. Ziegler in Pauly-Wissowa *Real-Encyclopädie der classischen Altertums wissenschaft*, vol. 13, col. 2316-81 (1927). (Ar. Ca.)

LYCOPODIUM, a genus of mosslike near-herbs, commonly called ground pine or club moss. It is one of two living genera of the Lycopodiaceae, a family of the Lycopsidea, a subdivision of the vascular plants comprising the club mosses and their allies, fossil and living. Probably 200 or more species exist, nearly cosmopolitan in distribution, but most abundant in the tropics. The 13 species found in North America occur most abundantly in the cool, wooded regions of the eastern United States and Canada. The Pacific coastal states and adjacent parts of Canada have only nine of these species. Great Britain has five, chiefly in mountainous districts.

The lycopods are spore bearers; their stems, covered with small, simple leaves, more or less spirally arranged, may be erect, prostrate, creeping, or epiphytic and pendent. No lycopod stem has a cambium. The fertile leaves (sporophylls) may be somewhat similar to the vegetative leaves, in which case they are present in alternating zones on the stem, or they may be aggregated in conical strobili at the tips of branches. In this case, the sporophylls may differ markedly in size and shape from the vegetative leaves. Each sporophyll bears on its upper surface a single, kidney-shaped spore case (sporangium) which produces large numbers of thick-walled, cutinized spores. Very few of these spores appear to germinate in nature. The evidence suggests an inability to absorb water. Scarifying the spore wall or centrifuging the spores in water at considerable speed causes many more to germinate.

When grown on a sugar-mineral salt nutrient medium, the germinated spores grow well and all species tried produce green, much-branched, rhizoid-bearing, hermaphroditic prothallia. By contrast, in the limited number of cases described from nature since the mid-19th century, the prothallia are green and branched if on

the surface of the ground or somewhat colourless and fleshy if below. The prothallia of all species described prove to have an endophytic fungus in symbiotic relation, possibly obligate.

The small size of the spores of *Lycopodium* and their high content of finely divided oil droplets make for inflammability. They have been used, as lycopodium powder, in fireworks and in flash-light photography.

See also PALEOBOTANY.

(R. H. We.)

LYCOPSIDA, a class (or subphylum) of spore-bearing vascular plants comprising the club mosses and their allies, living and fossil. Present-day lycopsids are grouped into four genera and 900-1,000 species of wide distribution but especially numerous in the tropics: *Lycopodium*, the club mosses or "ground pines"; *Selaginella*, little club mosses or spike mosses; the small, fleshy unique plant *Phylloglossum*; and *Isoetes*, the quillworts. These genera include diminutive creeping or shrubby plants. Representative extinct genera are *Lepidodendron* and *Sigillaria*, the tree lycopods, and *Protolopodendron*, a herbaceous *Lycopodium*-like plant. Lycopsids are known from rocks of Silurian Age (about 350,000,000 years ago) of the Paleozoic era. The remains of *Lepidodendron* and other extinct lycopods form most of the great coal beds of the world.

General Features.—All members of the class share certain morphological characteristics. Branching is fundamentally dichotomous, that is, the shoot tip forks repeatedly. The two branches that result may become equal in length or one may become longer than the other. The leaves are generally small, although they did achieve the length of one metre in the giant lycopod, *Lepidodendron*. Generally each leaf is narrow and has an unbranched midvein, the type of leaf referred to as a microphyll, in contrast to the megaphyll of the ferns and seed plants (Pteropsida), which generally has branched venation. The sporangia occur singly on the upper side facing the stem (adaxial side) of the leaf (sporophyll).

The Lycopsidea in general are characterized by the occurrence of strobili. A strobilus is an aggregation of sporophylls usually tightly appressed, forming a definite conelike structure. The

vascular tissue in the stem may occupy the centre of the axis (protostele) or form a cylinder around a central pith (siphonostele). There are no interruptions in the vascular cylinder where vascular strands diverge to leaves, as is true for the Pteropsida.

There are variations in the Lycopsidea in the occurrence of secondary growth, types of spores produced, types of gametophytes (the inconspicuous sexual stages) and other details. The following discussion pertains mainly to orders with living members.

Survey.—*Lycopodiales*.—This is an order of one family, consisting of two living genera (*Lycopodium* and *Phylloglossum*) and one extinct form known from cones only and perhaps referable to *Lycopodium* (*Lycopodites*). The club mosses (*Lycopodium*) include about 200 species, most of which occur in the tropics. They prefer acid conditions and open, semi-shady locations associated with forests. *Phylloglossum*, a highly specialized plant that dies down at each dry season and cannot be found until the next wet season, is restricted to Australia; an individual plant may be only three to five centimetres tall, and consists of only a few leaves and a strobilus.

In growth habit the sporophytes (the conspicuous asexual

stages) of species of *Lycopodium* may arise erect from a rhizome system or creep in habit. Many are epiphytes; i.e., they grow attached to tree branches or other supports. Branching is fundamentally dichotomous, but in species with well-developed rhizomes, one branch of a dichotomy usually becomes much longer and larger than the other one and remains close to the substrate. The shorter one may undergo several limited dichotomies and the ultimate upright branches terminate in strobili. The leaves may be spirally arranged or grouped in four vertical rows along the shoot. Each leaf, from two millimetres to almost three centimetres in length, has a single unbranched midvein (microphyll). Adventitious roots, initiated near the shoot tip, may grow vertically within the stem cortex for some distance before emerging. The roots branch dichotomously but no extensive root system is formed. In terrestrial species the roots have root hairs that function for a long time.

The stem is protostelic (without a central pith), but there is great variety in the disposition of xylem and phloem in the central vascular cylinder. Sporophylls may be aggregated into definite strobili or there may be simply "fertile" and "sterile" regions along a stem, the sporophylls resembling vegetative leaves. Often the sporophylls of compact strobili are quite different from the

vegetative leaves of the same plant. The kidney-shaped sporangia are yellow or orange and have short stalks. Reduction division (meiosis) occurs in the sporangium; thus the small tetrahedral spores have the haploid chromosome number. Spore morphology has become important in delimiting subgroups in the genus. (See also *LYCOPodium*.)

Although gametophytes are rarely found in nature, enough is known about them to recognize two types, based principally upon the mode of growth and nutrition. In some species the gametophyte, which develops from a spore, becomes a small, green plant growing on the surface of the soil; the time interval between spore germination and sexual maturity of the gametophyte may be eight months to one year. In other species, including nearly all those of the north temperate zone, the gametophyte is slower growing, and is dependent upon an associated fungus for continued growth. The plant may become carrot shaped or disc shaped (one to two centimetres in length or width); it is yellow to brown, but apparently can develop chlorophyll if the plant is growing near the soil surface where light can reach it. Generally a gametophyte of this type remains subterranean, and five or more years are required before it becomes sexually mature. Gametophytes are monoecious (the sperm-producing antheridia and the egg-producing archegonia occur on the same plant). Fertilization is accomplished by the biflagellate sperm (antherozoid) swimming to the archegonium. The embryo, or young sporophyte, consists of a shoot, root and haustorial "foot." One gametophyte may "support" more than one sporophyte for a period of time; but ultimately the sporophyte becomes physiologically independent of the gametophyte, and the latter dies.

Some information has accumulated on chromosome numbers in *Lycopodium*. In two species the sporophyte chromosome numbers are 28 and 156. For one species, *L. selago*, the large number of 260 has been reported. *Phylloglossum*, the very small, reduced plant, is reported to have 502 to 510 in each nucleus. Only a few ferns have higher numbers of chromosomes for vascular plants. (Large chromosome numbers are often considered to reflect the great antiquity of a group.)

Selaginellales.—One family and two genera (one fossil, one extant) constitute the order. In such a monotypic group the characteristics of the order, family and genus are the same. The living species are in the genus *Selaginella*, and the fossils are assigned to the genus *Selaginellites*. *Selaginella*, the small club mosses, with about 700 species, is of greatest diversity in the tropics. Whereas species of *Lycopodium* prefer acid soils, *Selaginella* may be found in alkaline situations; a few species, called resurrection plants, survive the rigours of desert habitats. The foliage leaves, only a few millimetres long, may be dark green or bluish and in some species are iridescent. As in *Lycopodium*, branching is fundamentally dichotomous. The sporophyte may consist of several upright branches from a rhizome, prostrate branches creeping along the surface of the soil or large, flat, erect frondlike side branches from strong rhizome systems. The entire branch system is often considered to be just a leaf upon casual observation by the untrained observer.

One of the distinctive features of *Selaginella* is the rhizophore, a prolike structure that originates at points of branching and that

FIG. 3.—SELAGINELLA KRAUSSIANA: (LEFT) CREEPING HABIT, WITH PROSTRATE STEM GIVING RISE TO RHIZOPHORES AND LEAFY BRANCHES; (RIGHT) CROSS SECTION OF STEM SHOWING PROTOSTELIC CONDITION OF VASCULAR SYSTEM

forms roots upon contacting the soil or a hard surface. Rhizophores are most readily seen in scrambling or scandent species. Morphologically the rhizophore is a leafless stem that in its early stages of development can give rise to leafy branches if the normally leafy branches of a dichotomy are cut off. The leaves are arranged as in *Lycopodium*, the occurrence of four vertical rows being common. Anisophylly (the occurrence of two sizes of leaves) is common in creeping and strongly rhizomatous species. As the rhizophore is a distinctive feature for *Selaginella*, so is the presence of an unusual structure on the adaxial side of a leaf. This is the ligule, a peculiar tongue-like outgrowth from the leaf surface near the leaf base. Leaves of *Lycopodium* and *Selaginella* can be distinguished on this basis. The structure can be observed in young leaves with a moderately good hand lens. The ligule appears very early in the development of a leaf. At maturity it is a surprisingly complex structure. The evolutionary origin and homology of the ligule are obscure. Functionally, it is believed that they are secretory organs that, by exuding water and possibly mucilage, serve to keep young leaves and sporangia moist. They are short-lived structures, becoming shrunken and inconspicuous in older leaves.

The protostele is the prevailing type of vascular cylinder with only a few species being siphonostelic. In protostelic types there may be two or more vascular cylinders at a given level in the stem. However, these seemingly independent vascular strands are interconnected at points of branching of the stem. The vascular cylinders are usually supported in an air space by trabeculae—elongated endodermal cells or strands of cortical cells.

Definite strobili are formed in *Selaginella*, and the sporophylls generally differ from the vegetative leaves, but not as much as in the species of *Lycopodium* that form definite strobili. There are two types of sporangia, termed microsporangia and megasporangia, and the sporophylls associated with them are termed microsporophylls and megasporophylls. A mature microsporangium may be red, yellow or brown, from the colour of the microspores within the sporangium. Megasporangia are usually a pale green or whitish. Numerous microspores are produced, and cell division within the microspore wall initiates male gametophyte development. These divisions may occur before the spores are shed from the microsporangium. Final development of the "male" gametophyte, or microgametophyte, usually occurs on the soil prior to the release of biflagellate sperms. Usually only four large megaspores are produced in a megasporangium because meiosis occurs in only one functional spore-mother-cell. Development of the "female" gametophyte, or megagametophyte, may also begin while the megaspore is still within the megasporangium: free nuclear divisions (without wall formation) occur for a time, but ultimately walls appear and the megagametophyte ruptures the megaspore wall. These final stages in development usually occur on the soil after the megaspore with the enclosed female gametophyte is shed from the megasporangium. Fertilization occurs when a biflagellate sperm swims to an archegonium. The young sporophyte remains

in physical contact with the megaspore and the enclosed female gametophyte tissue for some time.

Selaginella is said to be heterosporous because it produces two types of spores that give rise to two different types of sexual gametophytes.

Isoetes.—This order consists of one family and the extant genus *Isoetes*, the quillworts, which number about 65 species. *Isoetes* is a most interesting and enigmatic vascular plant. The plant body is relatively small, consisting of a short axis and tufts of leaves and roots. Many species are mistaken for certain aquatic grasses, which are seed plants. The majority of species occur in the cooler climates of the world and are usually immersed continually in water. Each leaf is in reality a sporophyll, bearing either a microsporangium or a megasporangium at its base on the adaxial side. Each leaf also has a ligule, a morphological feature similar to *Selaginella*. *Isoetes* differs from both *Selaginella* and *Lycopodium* in the occurrence of secondary growth in the stem and in the possession of a definite root-producing meristem that gives rise to sets of roots in a definite sequence. Annual top growth rises from a cormlike base that persists from one growing season to the next. The general processes of sexual reproduction are very similar to those in *Selaginella*, except that many more spores are formed per sporangium. In fact, the microsporangia of some species are the largest in vascular plants and produce immense numbers of spores.

A discussion of the extinct order Lepidodendrales can be found in PALEOBOTANY.

LYCURGUS, the lawgiver traditionally responsible for most of the institutions of ancient Sparta. For the institutions, see SPARTA; the primary problem about Lycurgus is the extent to which he can be regarded as a historical person and about the use that was made of his name.

The 7th-century Spartan poet Tyrtaeus, though he paraphrased

ALL BUT MATURE SPOROPHYTE REDRAWN FROM "A TEXTBOOK OF GENERAL BOTANY," FIFTH EDITION, BY GILBERT M. SMITH ET AL., BY PERMISSION OF THE PUBLISHER. FIG. 4.—LIFE CYCLE OF SELAGINELLA. CHROMOSOME COMPLEMENT INDICATED AS DIPLOID (2N) OR HAPLOID (N)

a document later associated with Lycurgus, certainly did not mention his name (he would have been quoted if he had, in view of the great interest later writers took in the lawgiver). Herodotus repeats an oracle of unknown date, ostensibly addressed to Lycurgus, which shows Delphi in doubt whether to treat him as god or man but inclining to the former: when this oracle was given, there can have been little definite historical information about him. Simonides (c. 556-468/467 B.C.) knew the tradition that he belonged to the Eurypontid royal house, but Herodotus in the middle of the 5th century was told at Sparta that he was an Agiad, and regent for his nephew Leobotes (a very early king). He was also told that Lycurgus brought most of his institutions from Crete, but he had heard elsewhere that they were brought from Delphi. In the next generation Thucydides, without naming Lycurgus, said that the Spartan constitution had not been altered since a date in the late 9th century; whereas Hellanicus seems to have ascribed Sparta's institutions to the legendary Dorian founders Eurysthenes and Procles. Later Xenophon, ascribing everything to Lycurgus, apparently thought him contemporary with the original Dorian foundation.

Thereafter the authorities are more consistent. By the middle of the 4th century it was accepted that Lycurgus belonged to the Eurypontid house and had been regent for Charillus, some steps lower in the genealogy than Leobotes, and on this basis hellenistic scholars dated him to the 9th century. This date held the field, though Aristotle had found his name on an inscription purporting to guarantee the truce for the Olympic games, traditionally founded in 776, and Timaeus (3rd century) took refuge in the thesis that there were two great figures named Lycurgus, at different dates. The story of the 9th-century reformer was further elaborated, and when Plutarch (1st-2nd century A.D.) came to write his life there was plenty of material, including his journeys to Egypt and elsewhere, and his bringing of the poems of Homer to Sparta. The bulk of the *Life* is naturally devoted to his reforms.

Some modern historians have accepted the ascription of most Spartan institutions to a reformer named Lycurgus in the 9th century. But the confident dates and details given by the later sources may reasonably be suspected, in the light of the variety and uncertainty of writers before 400 B.C. The Greeks found it easiest to discuss political and social institutions in terms of the personal intentions of a single founder—the peculiarity of Spartan institutions gave a special interest to the discussion of Lycurgus' intentions—and their ascription of particular institutions to particular founders is not always to be trusted. Thus it is asserted with equal confidence that Lycurgus instituted the office of ephor (q.v.), and that it was set up many years after his death: Xenophon ascribed to Lycurgus an organization of the army which almost certainly belongs to the 5th century: and it seems that the 3rd century reformers Agis IV and Cleomenes III used his name freely to sanction in detail their plans for redistribution of land. Even the admittedly archaic institutions are not necessarily all of the same date. Many scholars believe that an important group of reforms was carried out in the 7th century. If these reforms were, as seems likely, attributed to a Lycurgus at the time, this will be the Lycurgus of Herodotus' oracle, a shadowy figure of the past whose name was used to give authority to the reforms.

Herodotus reports that there was a shrine and cult of Lycurgus at Sparta in his day, as there was also later, and it has been supposed that he was originally a local god or hero, either a light-god or a wolf-god according to the derivation given to his name. The supposition, though possible, is not necessary: but there seems to be little advantage in arguing the question whether there was an actual person called Lycurgus or not.

See the ancient authorities referred to above, especially Plutarch's *Life*; and articles GREECE: *History* and SPARTA.

LYCURGUS (c. 390-324 B.C.), Athenian statesman and orator, was noted for his efficient financial administration and his rigorous prosecutions of public malefactors. He came from the ancient family of the Eteobutadae. He supported Demosthenes (q.v.) in opposing Macedonian expansion, but first became prominent in 338. During the 12 years which followed the Athenian

defeat at Chaeronea (338-326) he controlled the state finances either directly or through his nominees. He is said to have increased the annual public revenues from 600 to 1,200 talents. His other activities included reforming the constitution of the army, remodeling the fleet, repairing dockyards and finishing the arsenal designed by the architect Philo. He carried out an extensive building program, prominent in which was the reconstruction in stone of the Dionysiac theatre (see ATHENS). An interesting item of his legislation was a measure to make and preserve official copies of the plays of the three great tragedians, Aeschylus, Sophocles and Euripides.

Lycurgus looked beyond the material improvement of Athens. He was inspired by a mission to raise the level of public and private morals. Himself an austere pious man, he relentlessly demanded the same standards from others. Apart from fostering religious cults and traditions, he brought numerous prosecutions against those who had failed in their duty toward god or state.

Fifteen of his speeches existed in ancient times. Apart from minor fragments, only one, *Against Leocrates*, has survived. Leocrates had fled from Athens during the panic which followed the battle of Chaeronea, and on his return about six years later was prosecuted by Lycurgus for treason. The speech is an impersonal homily on patriotism, rather than an argument on specific legal points. There are historical digressions and long poetical quotations. Stylistically it shows traces of Isocrates' influence, but sentence structure is careless and haphazard. Even so the vigour and obvious sincerity of the speaker command attention.

LYCURGUS, the name of a number of Greek mythological personages, the most famous a king who opposed the god Dionysus. Homer describes how Lycurgus chased Dionysus' nurses on Mt. Nysa and drove him to take refuge with Thetis in the sea. Other authors made Lycurgus king of Thebes (or, after Aeschylus, usually of Thrace); for his impiety he was driven mad and first killed his family and finally hacked off his own limbs in mistake for vine branches. (H. W. Pa.)

LYDD, a municipal borough (1885) of Kent, Eng., 72 mi. E.S.E. of London by road and rail, comprises the old town of Lydd and the coastal districts of Dungeness (q.v.), Lydd-on-Sea and Greatstone. It has 9½ mi. of coast line and is the most southerly town in Kent. Pop. (1961) 2,685.

Adjacent to the High street are the Guild hall and the parish church of All Saints, which incorporates a portion of a stone Saxon church and has a Perpendicular tower with rich vaulting within; the tower is a widely known landmark. Cardinal Wolsey was once vicar there. On and adjacent to land known as the Rypes, granted to the barons of Lydd in the 8th century as a reward for their valour in repelling the Danes, are a large military camp with artillery, rifle and mortar ranges (the town gave its name to the shell explosive lyddite, first tested there), and an extensive housing estate. Close to the northeastern approach to the town is Lydd (Ferryfield) airport with a 20-minute car ferry service to the continent. The inland portion of the borough is mainly agricultural, and there are extensive beach quarrying and crushing plants. The coastal area attracts a great many summer visitors.

Lydd is a corporate member of the Confederation of the Cinque Ports, being a limb of Romney. The liberties and customs of the Cinque Ports were granted to Lydd in 1155. Until the early 14th century the town was an island, but it is now three miles from the sea. (Cl. L. W.)

LYDDA: see LOD.

LYDGATE, JOHN (c. 1370-c. 1450), English poet, known principally for long moralistic and devotional works of greater fertility than genius, was born at Lidgate in Suffolk. In his *Testament* he says that while still a boy he became a novice in the Benedictine abbey of Bury St. Edmunds but until the age of 15 was idle and heedless of his duties. He was professed a monk there, and became a priest also in 1397. He must have spent some time in London, and seems to have been in Paris about 1421; but

from 1415 he was apparently mainly at Bury, except for the years from 1421 to 1432, when he was prior of Hatfield Broad Oak in Essex. The date of his death is uncertain, but it may well have been in the autumn of 1449.

Lydgate's most conspicuous quality is his sheer productiveness: no fewer than 145,000 lines of his verse survive. (His only prose work, *The Serpent of Division*, 1422, an account of Julius Caesar, is brief.) His poems vary enormously in matter and treatment, from vast narratives such as *The Troy Book* and *The Fall of Princes* to occasional poems of a few lines. Of the longer poems the most attractive is the allegory *Reason and Sensuality*, a comparatively early work (c. 1408) on the theme of chastity, translated from the French. It contains some fresh and charming descriptions of nature, in well-handled octosyllabic couplets. *The Troy Book*, begun in 1412 at the command of the prince of Wales, later Henry V, but not finished until 1421, is a verbose and pedestrian rendering, in decasyllabic couplets, of Guido delle Colonne's *Historia troiana*. It was closely followed by *The Siege of Thebes*, in which the main story is drawn from a lost French romance but embellished by features from Boccaccio; and the preface looks directly to Chaucer, Lydgate presenting himself as a Canterbury pilgrim invited by the Host of the Tabard inn to join the famous company and to tell his tale. In 1426 Lydgate undertook a translation of Guillaume de Deguileville's *Le Pèlerinage de la vie humaine* as *The Pilgrimage of the Life of Man*, a stern and disagreeable allegory, again of excessive length, and between 1431 and 1438 he was occupied with *The Fall of Princes*, translated into rhyme royal from a French version of Boccaccio's *De Casibus virorum illustrium*. In addition to these major works he wrote love allegories such as *The Complaint of the Black Knight* and *The Temple of Glass*, saints' lives, versions of Aesop's fables, a great many poems commissioned for special occasions such as Henry VI's entry into London and "mummings" at various places, and lyrics both religious and secular.

So great a volume of work is naturally uneven in quality, and it must be admitted that the proportion of good poetry is small. Lydgate's pervasive faults are prolixity and lack of precision. He uses innumerable tags and clichés and repeats himself endlessly. His diction is often overlaid with "aureate" neologisms from French and Latin, and his lines so often stumble, if read according to normal scansion, that they have come to be regarded as based on a distinct "broken-backed" rhythm having affinities with the alliterative metre. Yet with all his faults Lydgate can at his best write graceful and telling lines. His reputation long equaled Chaucer's, and he exercised immense influence on succeeding poets for nearly a century.

See also ENGLISH LITERATURE: *From Chaucer to the Renaissance*.

BIBLIOGRAPHY.—There were early editions of many of Lydgate's works by William Caxton, Wynkyn de Worde and Richard Pynson. Editions of the most important have been published by the Early English Text society; e.g., *The Temple of Glass*, ed. by J. Schick (1891); *Reason and Sensuality*, ed. by E. Sieper (1901-03); *The Assembly of the Gods*, ed. by O. L. Triggs (1896; repr. 1957); *The Pilgrimage of the Life of Man*, ed. by F. J. Furnivall and K. B. Locock (1899-1904); *The Fall of Princes* and *The Troy Book*, ed. by H. Bergen (1924-27; 1906-35); *The Siege of Thebes*, ed. by A. Erdmann and E. Ekwall (1911-30; repr. 1960); *Minor Poems*, ed. by H. N. MacCracken (1911-34; repr. 1961). Of other editions, the most important is *The Life of Our Lady*, by J. A. Lauritis et al. (1961). See also E. P. Hammond, *English Verse between Chaucer and Surrey* (1927); C. S. Lewis, *The Allegory of Love* (1936), pp. 239-243, 264-278; and "The Fifteenth-Century Heroic Line," in *Essays and Studies of the English Association*, xxiv (1938), pp. 28-41; H. S. Bennett, *Chaucer and the Fifteenth Century* (1947), pp. 110-111, 138-146 and bibliography; W. F. Schirmer, *John Lydgate. Ein Kulturbild aus dem 15. Jahrhundert* (1952; Eng. trans. 1961). (N. D.)

LYDIA, the land of the Lydians (Gr. *Ludoi*), an inland people of western Asia Minor, briefly prominent in near eastern history in the 7th and 6th centuries B.C. Their capital was at Sardis (q.v.), with its almost impregnable citadel (now much eroded) at the source of the Pactolus torrent, a tributary of the Hermus (Gediz) and a source of wealth to the city and country from its alluvial gold-bearing sands.

The Lydian name does not appear in Homer; in the list of

Trojan allies, their central district under Mt. Tmolos (Boz Dag) and round the Gygaean lake (Marmara Golu) is assigned to the Maeonians (*Iliad*, ii, 864-866). The relations of the two peoples were discussed in ancient times, "some saying that they were the same, and some different" (Strabo, xii, p. 572); Herodotus (i, 7) considered that they were the same, but had changed their name. It seems not unlikely that, while the main body of the people may have been of old Anatolian stock, the Lydian name may have been introduced by Early Iron Age conquerors. The language, scantily known from glosses and from inscriptions in an alphabetic script akin to eastern Greek archaic alphabets, has been thought to be Indo-European, but dubiously. Connections with Caucasian languages remain possible (see ANATOLIAN LANGUAGES).

The first appearance of Lydians in historical records is in a famous tablet of Ashurbanipal of Assyria, which recounts, about 660 B.C., how "Gugu, king of Luddi, a far land at the crossing of the sea, of which the kings my fathers had not heard the name," accepted (it is alleged) Assyrian overlordship and concerted operations against barbarian invaders, the Gimirri (Cimmerians, q.v.). Gugu captured and sent in chains to Assyria two Cimmerian chiefs; later, however, he broke off the alliance and sent troops to the aid of the refractory Psamtik I (Psammetichus) of Egypt (q.v.); Ashurbanipal ascribes to the answering of his prayers for vengeance Gugu's subsequent defeat and death (about 648) and relates that his son and successor returned to his allegiance.

Gugu is undoubtedly Gyges (q.v.) of Lydia. The fact that the name of his people was new to the Assyrians is a precious piece of information; for it was the same Cimmerian invaders who had lately destroyed the Phrygian empire of Midas (q.v.), with whom the previous Assyrian kings had had dealings. It may well have been the breaking of this power which enabled the Lydians, dwelling south and west of Phrygia and so less (though not much less) exposed to Cimmerian depredations, to rise from obscurity. Lydia had had its own earlier dynasties, according to Herodotus (i, 7 ff.) and to the 5th-century native historian Xanthus, whose work, in Greek, is known only through quotations: the Heraclid dynasty (perhaps a dynasty claiming descent from the lion-taming god Sardon) and, still earlier and more obscure, an alleged dynasty descended from Atys, in whose time, according to Herodotus' famous and unrefuted assertion (i, 94), an expedition, in time of famine, sailed to colonize Etruria (see ETRUSCANS). But neither history nor archaeology has shed much more light on these dynasties. Essentially, the Lydian kingdom so well known to the eastern Greeks was born in the crisis of the 7th century. Under its new, military dynasty, the Mermnadæ or "House of the Hawk," Lydia emerged as a warlike power. The "Ludim, that handle and bend the bow," are known even to the gentle Hebrew Jeremiah, among the mercenaries of Egypt (Jer. xlv, 9).

To the Ionians on the coast, Lydia was formidable. The kings, like the dynasty of Phrygian Midas before them, were well aware of the existence of lands to the west, and had dealings with the oracle at Delphi (Herodotus, i, 13 ff., 46 ff., etc.). Great traders, though no sailors themselves, the Lydians coveted not only the lands of Ionia, but the harbours. Gyges, in an interval between Cimmerian invasions, overthrew with his powerful cavalry the knights of Colophon, hitherto the strongest Ionian power on land; the poet Mimnermus of Colophon (c. 630), remembering these wars, gives the first extant Greek mention of the Lydians by name. Ardys, Gyges' son, captured the small port of Priene. Priene's neighbour, the wealthy Miletus, sustained bloody defeats; but its seafaring economy proved too tough to be broken by the raiding of its farms, and it was admitted to alliance. It may well be that the great outpouring of Ionian colonists to the Black Sea just at this time was stimulated in part through the cutting short of Ionia's lands by Lydia.

Allyattes, son of King Sadyattes the son of Ardys, was the most successful of the five Mermnad kings and had the longest reign (c. 617-560 traditionally). He drove the last Cimmerians far to the east; and he captured Smyrna, using not only cavalry raiding tactics, but the siegecraft of the east. The remains of the huge mound, engulfing olive yards in its way, which he threw up against the walls, have been discovered during the Turco-British excavations.

tions, and fragments of 7th-century pottery therein provide valuable dating evidence. But in his time new dangers also began to appear. Cyaxares the Mede, the destroyer of Assyria, threatened his eastern frontier. Alyattes held his ground in a severe war, the course of which Thales (*q.v.*) the Milesian is said to have influenced by predicting an eclipse (585 or 582?). Peace was made through the mediation of the kings of Babylon and Cilicia (*c.* 580?), and under Alyattes' son, the wealthy Croesus (*q.v.*), the kingdom seemed destined to reach even greater heights of power and prosperity. Croesus gained unprecedented successes against Ionia, capturing Ephesus and ultimately nearly all the mainland cities. But in Iran, meanwhile, supremacy was gained by the formidable Persians. Croesus, whose sister had been married to the last king of the Medes, made alliance with Babylon, Egypt and Sparta; but he was outstripped by the military genius of the great Cyrus (*q.v.*); and the fall of his citadel before Persian rock-climbing enterprise brought the Lydian monarchy to a final and dramatic end (*c.* 546 or 540).

Little more is heard of the Lydians as a people, and nothing more, once they were disarmed after the early revolt of Paktyas (Herodotus, i, 153 ff.), of their military qualities; a curious fact, suggesting that Lydian conquests were the work of an aristocracy (the *Ludoi* proper?) which had already been bled white by war. Never again was their name that of an independent state; and by the beginning of our era (if we may judge by a somewhat corrupt passage of Strabo, xiii, p. 631) their language had disappeared from the lowlands. The personal names, Lydos, Lydia, survived in Greek (originally for Lydian slaves) and the feminine form, through St. Paul's convert from Thyateira (Acts xvi, 14), has entered the Christian repertoire.

On Lydian manners and customs, archaeology has shed little light: the American excavation of Sardis (*q.v.*) discovered less of the thatched huts of the Lydian bazaar-city than of the Hellenistic and Roman epochs. In essence, we are still dependent on Herodotus, whose summary (i, 94) is that "their customs are like those of the Greeks, except that their girls engage in prostitution." The prostitution, by which they earned their dowries, had no doubt, as in Babylon, a religious sanction. Herodotus adds that they were the first men known to strike and use coins of gold and silver; and they were the first *kapeloi* ("retailers"; *i.e.*, permanent shops were something which the Greeks first saw in commercial Sardis). From their trade between east and west arose the important step which their kings took, in stamping small ingots of gold, silver or (most frequently) of the mixture "pale gold" or electrum; a guarantee, originally, of the quality rather than of the weight, since the primitive coins were of irregular shape and could be, and were, often clipped. It was an invention, made probably in the mid-7th century or later, rather than about 700 as was formerly believed, which the Greeks were quick to adopt, and which played an important part as a catalyst in the commercial revolution that transformed Greek civilization in the course of the next 150 years (see NUMISMATICS).

(1951); *Sardis* (excavation reports of the American Society for the Excavation of Sardis; in progress) (1916-); A. R. Burn, *The Lyric Age of Greece* (1960). On the date of the first Lydian coinage, see E. S. G. Robinson, "The Coins from the Ephesian Artemision Reconsidered," in *Journal of Hellenic Studies*, lxi, 156 ff. (1951).

LYE, the name given to the solution of alkaline salts obtained by leaching or lixiviating wood ashes with water; to solutions of a caustic alkali (sodium or potassium hydroxide); or, more generally to any strong alkaline solution or solid, especially one used as a detergent.

In the United States it is the common name for sodium hydroxide. See **ALKALI**; **ALKALI MANUFACTURE**.

LYELL, SIR CHARLES (1797-1875), British geologist, author of *Elements of Geology*, a standard work on stratigraphical and paleontological geology, was born on Nov. 14, 1797, on the family estate of Kinnordy, Forfarshire, Scotland. His father, Charles Lyell (1767-1849), was known both as a botanist and as the translator of the *Vita Nuova* and the *Convivio* of Dante: the

plant *Lyellia* was named after him. As a boy Lyell had a strong inclination for natural history, especially entomology. In 1816 he entered Exeter college, Oxford, where the lectures of William Buckland first attracted him to geology. After graduating he entered Lincoln's Inn, London, and in 1825 he was called to the bar and went on the western circuit for two years. In 1819 he had been elected a fellow of the Linnean and Geological societies; in 1823 he went to France with introductions to Georges Cuvier and other scientists and in 1824 made a geological tour in Scotland in company with Buckland. In 1826 he was elected fellow of the Royal society (F.R.S.) and in 1827 he finally abandoned law for geology.

He had already begun to plan his chief work, *The Principles of Geology* (3 vol., 1830-33). With Sir Roderick Murchison he wrote joint papers on the volcanic district of Auvergne and the Tertiary formations of Aix-en-Provence. He then studied the marine remains of the Italian Tertiary strata and conceived the idea of dividing the geological system into three or four groups, characterized by the proportion of recent to extinct species of shells. To these groups he gave the names later universally adopted—Eocene (*dawn of recent*), Miocene (*less of recent*) and Pliocene (*more of recent*)—and with the assistance of G. P. Deshayes he drew up a table of shells in illustration of this classification. Between 1830 and 1876 12 editions of *The Principles of Geology* were published, each so much enriched as to form a complete history of the progress of geology during that interval.

In 1838 Lyell published the *Elements of Geology*, which became a standard work on stratigraphical and paleontological geology. This book, which was based on lectures, went through six editions in Lyell's lifetime. In his third great work, *The Antiquity of Man* (1863), he gave a general survey of the arguments for man's early appearance on the earth, derived from the discoveries of flint implements in post-Pliocene strata in the Somme valley and elsewhere; he discussed also the deposits of the Glacial epoch, and in the same volume he expressed his support of Charles Darwin's theory of the origin of species.

In 1834 Lyell went to Denmark and Sweden, the result of which was his Bakerian lecture to the Royal society "On the Proofs of the gradual Rising of Land in certain Parts of Sweden." He also brought before the Geological Society of London a paper "On the Cretaceous and Tertiary Strata of Seeland and Möen." In 1835 he became president of the Geological society. In 1837 he was again in Norway and Denmark, and in 1841 traveled through the United States, Canada and Nova Scotia. This last journey, together with a second one to America in 1845, resulted not only in papers, but also in two works not exclusively geological, *Travels in North America* (1845) and *A Second Visit to the United States* (1849). He estimated the rate of recession of the falls of Niagara, the annual average accumulation of alluvial matter in the delta of the Mississippi, and studied those vegetable accumulations in the "Great Dismal Swamp" of Virginia, which he afterward used in illustrating the formation of beds of coal. He also studied the coal formations in Nova Scotia and discovered, in company with Sir John W. Dawson of Montreal, the earliest known land shell, *Pupa vetusta*, in the hollow stem of a fossil tree club moss, *Sigillaria*.

On a visit to Madeira and Tenerife he accumulated evidence on the age and deposition of lava beds and the formation of volcanic cones. He revisited Sicily in 1858, and his observations upon the structure of Etna refuted the theory of "craters of elevation" upheld by Christian von Buch and Jean Élie de Beaumont.

Lyell was knighted in 1848 and created a baronet in 1864, in which year he was president of the British association at Bath. He died in London on Feb. 22, 1875, and was buried in Westminster abbey. The Lyell Medal was established in 1875 under the will of Sir Charles Lyell, to be awarded annually (or from time to time) by the council of the Geological society.

See *Life, Letters and Journals of Sir Charles Lyell, Bart.*, ed. by his sister-in-law, Mrs. Lyell, 2 vol. (1881); T. G. Bonney, *Charles Lyell and Modern Geology* (1895).

LYLE OF WESTBOURNE, CHARLES ERNEST LEONARD LYLE, 1ST BARON (1882-1954), British industrialist and member of parliament, was born at Highgate, London, on

July 22, 1882, the son of Charles and grandson of Abram Lyle, the founder of the sugar refining firm of Abram Lyle and Sons, Ltd. Educated at Harrow and Trinity hall, Cambridge, he joined the family business in 1903. He became managing director of the amalgamated Tate and Lyle, Ltd., in 1921, chairman in 1922 and president in 1937. He was also greatly concerned with the humanizing and efficient running of hospitals, being chairman of Queen Mary's hospital at Stratford, London, from 1915 to 1931 and deputy president from 1932.

In 1918 he was elected as Coalition Unionist member of parliament for the Stratford division of West Ham, holding this seat until 1922. He was a member for Epping in 1923-24 and for Bournemouth in 1940-45. His public work was recognized in 1923 by a knighthood, and in 1932 he was created a baronet. In 1945 he was raised to the peerage. At sport he represented England at lawn tennis and he also became president of the Professional Golfers' association. He died at Bournemouth, Hampshire, on March 6, 1954. (X.)

LYLY, JOHN (1554?-1606), English author most famous for his novel, *Euphues*, was born in Kent in 1553 or 1554. After leaving Oxford, he apparently entered the service of Lord De La Warr, and in 1580 that of Edward de Vere, earl of Oxford. In 1578 he soared to fame through the publication of *Euphues, or the Anatomy of Wit*. *Euphues and His England* appeared in 1580. The most fashionable English writer in the 1580s, Lyly was praised as the creator of "a new English," and as Edward Blount, his first editor, reported in 1632 (in the *Six Court Comedies*), "that Beautie in Court, which could not Parley, *Euphuisme*, was as little regarded; as shee which now there, speakes not French."

After the publication of *Euphues*, Lyly abandoned the novel and devoted himself almost entirely to playwriting. It is known that c. June 1583, through Oxford's influence, he gained control of the first Blackfriars theatre and dabbled in theatrical ventures that led, a year later, to brief imprisonment for debt. In this theatre his earliest plays, *Campaspe* and *Sapho and Phao*, were produced by a company called Oxford's boys, perhaps a short-lived amalgamation of Paul's boys and the children of the Chapel. That Lyly ever served as vice-master of Paul's (a nonexistent post), as has been alleged, seems rather implausible. All that remains certain is that all Lyly's plays, except *The Woman in the Moon*, were presented by Paul's boys, either alone or with the Chapel children.

Pappe With an Hatchet (1589) was a tract in defense of the bishops in the Marprelate controversy. About the same time (probably in 1588) Lyly presumably received at least a promise of the reversion of the mastership of the Revels whenever Edmund Tylney (appointed 1579) should retire. After the inhibition of Paul's boys (c. 1590), however, Lyly's fortunes rapidly declined. Though a member of parliament during the 1590s, he apparently suffered from both a meagre income and a disastrously waning popularity caused by the rise of Thomas Kyd, Robert Greene, Christopher Marlowe and Shakespeare. Nor was the mastership of the Revels any nearer; Tylney held the post till 1610. In despair Lyly finally addressed to Elizabeth I two bitter petitions, dated conjecturally 1598 and 1601. In the first he complained of having wasted ten years hanging about the court in hope of preferment; his increasing despondency may be gauged from the singularly reckless tone of the second. "Thirteene yeeeres your Highnes servant; but yet nothinge. Twenty frendes, that though they saye they will be suer, I finde them suer to be slowe. A thousand hopes, but all nothinge, a hundred promises, but yet nothinge. Thus castinge up the Inventorye of my frendes, hopes, prommisses and tyme: the *summa totalis* amounteth in all to just nothinge." Blount says vaguely that Elizabeth "graced, and rewarded" him, but of this there is little evidence, though he may have received something out of the Essex forfeitures. He was buried in London on Nov. 30, 1606. He had married in 1583 Beatrice Browne of Mexborough, Yorkshire, by whom he had several children.

Comedies.—The dating of Lyly's plays remains conjectural, though scholarly opinion has settled upon the following dates of probable composition: *Campaspe* and *Sapho and Phao* (1583,

in this sequence); *Gallathea* (1584); *Endimion* (1586-87); *Love's Metamorphosis* and *Midas* (1589, in this sequence); *Mother Bombe* (1589-90); and *The Woman in the Moon* (1594-95). Of these all but the last are in prose. During the 1590s Lyly also wrote a number of entertainments for aristocratic audiences. Lyly's comedies mark an enormous advance upon those of his predecessors and give him a secure place among the playwrights who distinguished the last two decades of Elizabeth's reign. His skill in acclimatizing to England Italianate pastoral and Latinate comedy of intrigue; his ability to bring together into a cohesive plot fanciful and mythological characters and characters from the lower ranks of English life; his delicate analysis by allegorical means (both topical and philosophical) of the nature of love, as the Renaissance understood it; and the grace and charm of his witty dialogue set aesthetic standards that younger, more gifted dramatists dared not ignore. How these standards were met and surpassed by Shakespeare can be seen in such plays as *A Midsummer Night's Dream* and *As You Like It*. Lyly's classical and pastoral plots and characters, and his lapses into Renaissance pedantry, may seem anemic to modern readers; nevertheless his finest play, *Endimion*, precious though it be, remains a masterpiece. Francis Meres in *Palladis Tamia* (1598) cites Lyly as among "the best for comedy," and Ben Jonson lists him among the foremost rivals whom Shakespeare outspung.

Euphues.—It was as the author of *Euphues*, however, that Lyly made his most enduring impression upon the Elizabethan world. This essentially Renaissance "novel" introduced a new sense of form into English prose style. Lyly's preoccupation with the exact arrangement and selection of words, with balance, antithesis and alliteration, demonstrated that the English language could be disciplined into a flexible vehicle capable of competing on equal terms with Latin and Greek. Lyly was not the first to experiment with the artificialities of euphuism (*q.v.*), but he brought the style to its highest point and through his very exaggerations conferred a lasting benefit upon English prose. Euphuism served as one model for the malleable prose of Shakespeare, who paid Lyly the final compliment of parodying the style in *1 Henry IV* (II, iv), where Hal and Falstaff in the famous "play extempore" burlesque King Henry's euphuistic grandiloquence.

LYME REGIS, a municipal borough and seaside town in the West Dorset parliamentary division of Dorsetshire, Eng., 25 mi. W. of Dorchester by road, is situated at the mouth of a narrow valley opening upon a fine coast line of almost vertical cliffs made of horizontal layers of blue-gray limestones and shales which contain many fossils. Pop. (1961) 3,526. The beach is shingle with sand at low tide and there is a small harbour between the jetty, on the east, and the massive curved wall known as the Cobb, which also forms a pier. The picturesque town, built on a steep hill, contains many Georgian houses and the church of St. Michael the Archangel, which is mainly Perpendicular with a Norman tower. The chief industry is the tourist trade. A Royal Air Force marine craft unit base was established in 1938.

Three manors of Lyme are mentioned in 1086 and the town was first known as Lyme Regis in 1316. It was a port in 1234 and was granted a charter by Edward I in 1284, making it a free borough with a merchant guild. At that date it was trading with France and by 1311 it was an important port. Further charters were granted by Elizabeth I (1591), James I, Charles II and

William III. Lyme returned two members to parliament from 1295 to 1832 when the membership was reduced to one; it was disfranchised in 1867. Fairs were granted in 1553 for Feb. 1 and Sept. 20, but are no longer held. In 1685, before the battle of Sedgemoor, James, duke of Monmouth, landed at the Cobb which is also associated with Jane Austen's *Persuasion*. Sir George Somers (1554-1610), who first settled the Bermudas, Thomas Coram (1668-1751), who started the London Foundling hospital, and Mary Anning (1799-1847), who in 1811 found the fossilized remains of an ichthyosaurus (now in the British Museum [Natural History], South Kensington, London), were natives of Lyme.

LYMINGTON, a municipal borough and seaport in the New Forest parliamentary division of the county of Southampton (geographical Hampshire), Eng., on the river Lymington where it flows into the Solent, and 18 mi. S.W. of Southampton by road. It is bordered on the north by the New forest (*q.v.*). Pop. (1961) 28,642. Stone Age flint instruments and a Bronze Age burial urn have been found in the district and nearby was a Roman camp. In Domesday Book, Lymington is called Lentune and its first charter, one of the earliest in England, was granted by Baldwin de Redvers, 2nd earl of Devon, in 1150 and celebrated in 1950 by a week's festivities. The 6th earl granted another charter extending the borough (called old and new boroughs) to contain about 105 ac.; this remained unaltered until 1888 when Old and New Lymington were formed. The charter of Isabella de Fortibus, in 1270, gave almost complete freedom to the burgesses. These charters were later confirmed but no alteration has ever been made by the crown. The charter of 1605, formally incorporating the borough, remained in force until 1835 when, under the Municipal Corporations act, the government of the town (by a mayor and burgesses) was reformed. In 1932 the borough was extended to include Milford-on-Sea, New Milton (a holiday resort), Barton-on-Sea (famous for fossils), Hordle, Pennington (where there is a bird sanctuary on the marshes) and part of Sway. From 1584 until 1867, when the number was reduced to one, two members were returned to parliament; in 1885 the representation was merged in that of the county. Two fairs were granted in the 13th century and were for centuries important events in May and October. The present Saturday market is also ancient but declined in magnitude with the coming of the railways.

The first mention of salt works, later very important, is in a grant of tithes to Quarr abbey in 1147. The old borough was made a port in Henry I's reign and rivaled Southampton in prosperity, chiefly because of the salt industry. By 1845 the salt pans, or salterns, were worked out and the industry came to an end. Yachting and the building of yachts and other craft have been carried on since the early 19th century and the other main industry established in 1919) is the making of piston rings. Regular passenger and car ferries serve Yarmouth in the Isle of Wight.

LYMPH AND LYMPHATIC SYSTEM. The lymphatic system consists of two main components: (1) a system of closed tubes, the lymphatics, containing a fluid, the lymph; and (2) the lymphoid complex, an aggregate of different types of lymphoid tissue containing varying combinations of cells, among which lymphocytes predominate. Scattered lymphocytes also occur in large numbers throughout the body. Though the two main components of the lymphatic system are closely associated, they are best considered separately for descriptive purposes.

This article is divided into the following sections:

- I. Lymph and Lymphatics
 1. Structure and Arrangement of Lymphatic Vessels
 2. Composition of Lymph
 3. Amount of Lymph
 4. Relation of Lymph to Lymphoid Tissue
 5. Formed Elements in Lymph
 6. Mode of Production of Lymph
 7. Structure and Properties of Blood Capillary Endothelium
 8. Propulsion of Lymph
 9. Pressure in Tissue Spaces
- II. Lymphoid Complex, Lymphoid Organs and Lymphoid Tissues
 1. Total Amount of Lymphoid Tissue
 2. Age Changes
 3. Relation Between Different Members of the Lymphoid Complex
 4. Lymph Nodes

5. Subepithelial Lymphoid Tissues
6. Lymphoid Tissue in the Spleen
7. Thymus
8. Hemolymph Nodes
9. Lymphoid Tissue in Bone Marrow
10. Functions of Lymphoid Tissue

III. Lymphocytes

1. Genetic Relations of Lymphocytes
2. Production of Lymphocytes and Entry Into Blood
3. Fate of the Lymphocytes
4. Function of the Lymphocyte
5. Lymphoid Tissue and Virus Infections
6. Lymphoid Tissue and the Endocrine System

IV. Diseases of the Lymphatic System

1. Lymphadenitis
2. Tuberculous Lymphadenitis
3. Lymphangitis
4. Filarial Infestation: Elephantiasis
5. Reticuloses
6. Hodgkin's Disease (Lymphadenoma)
7. Reticulo-Sarcoma
8. Leukemia

I. LYMPH AND LYMPHATICS

In the higher animals the blood vessels form, with one or two possible exceptions, a closed system in which the most numerous vessels are the thin-walled capillaries. Through the capillary walls materials pass from the blood to the tissue fluid, which surrounds the individual cells and is in close contact with them. The term "tissue fluid" is a convenient one, but it must be emphasized that under normal circumstances it contains little if any free fluid. It consists of a gelatinous material, through which fluid can readily pass, but is not normally "free" in the sense that it forms localized accumulations. The water is associated with the colloid gel which forms the ground substance of the connective tissue, consisting in the main of mucopolysaccharide protein complexes, in which are embedded in varying proportions collagen and elastic fibres. It is probable that fluid moves through the connective tissues in thin films, between and around the fibres, by the action of surface forces. P. D. McMaster and R. J. Parsons (1939) refer to these as "captured" films. It is only when there is inflammatory or other edema that the accumulation of free fluid in pools may be observed, because of hydration of the colloid gel beyond a certain point.

The tissue fluid acts as a middleman in the transport of substances between the blood and the tissue cells (*see also* CIRCULATION OF BLOOD). Water and crystalloids can diffuse freely and rapidly in and out of the blood through the endothelium of the blood capillary. In addition, the hydrostatic pressure in the capillary causes fluid to filter out into the tissues. The extent and speed of the movement of water and crystalloids has been shown very clearly by the use of heavy water (G. Hevesy and C. F. Jacobsen, 1940) and radioactive isotopes. L. B. Flexner and his colleagues showed that in man 105% of plasma water and 78% of plasma sodium are exchanged per minute, while in the guinea pig the water exchange is even greater (140%). The absolute figures in man may be gauged from the fact that in the human adult the total blood volume is about 5 l., and of this approximately 3 l. are plasma, separated by the capillary endothelium from 10-12 l. of extravascular tissue fluid. Rapid fluid movements are essential if the composition of the tissue fluid is to remain reasonably constant.

Though the capillary endothelium so readily permits the free passage of water and crystalloids, it holds back most of the blood proteins. However, possibly as a result of the relatively high pressure of blood within the capillary, protein molecules do occasionally escape into the tissues. Over a 24-hour period something like 50% or more of the total plasma proteins leave the blood, the smaller albumin molecules escaping more freely than the larger molecules such as globulin. Furthermore, in some parts of the body, protein leaves the blood stream more freely than in others. Once the protein molecules have passed out of the capillaries they cannot be directly reabsorbed into the blood. Some of this extravascular protein may be used by the cells, but most of it can be removed only via the lymphatic capillaries. The prime purpose of the lymphatic system is to

drain away from the tissues any excess protein which has escaped from the blood vessels and ultimately to return it to the blood by the main lymph ducts entering the veins. It would follow from this that wherever there are blood capillaries, lymphatic capillaries must also be present. In general this is true, and exceptions, such as the central nervous system, the bone marrow, the splenic pulp and possibly the skeletal muscle bundles, are due to local circulatory peculiarities which render the presence of lymphatics unnecessary.

1. Structure and Arrangement of Lymphatic Vessels.—

The lymphatics begin as a network of capillaries with blind extremities; like the blood capillaries they are separated from the tissue fluid by a continuous layer of thin cells called endothelium (see fig. 1). Though this endothelium looks very like that of the blood capillary, it is much more freely permeable to large molecules such as protein and even to particulate matter, which therefore readily enters the lymphatics after injection into the tissue spaces. It was at one time thought that the lymphatics communicated directly with the tissue spaces, through small openings or stomata, but it is now believed that the lymphatic system is completely closed. From the network of lymphatic capillaries there emerge plexuses of larger vessels with thicker walls, but unlike the veins these do not undergo progressive increase in calibre as they near their destination. The smallest lymph capillaries consist of a single layer of flattened endothelial cells, but the larger vessels resemble veins in having an inner coat of endothelium, a middle unstriated muscle coat and an external fibrous coat.

Valves are numerous, even in vessels of very small calibre, though they are not present in the capillaries. They usually consist of two cusps, set so as to prevent flow toward the periphery. When the vessels are engorged the sites of the valves are marked by constrictions, producing a beaded appearance. The lymph plexuses of the organs and tissues are drained by the lymphatic trunks, which usually course with the main blood vessels of the part. The main trunks from the hind limbs and abdominal organs are united into one large vessel, the cisterna chyli, from which the thoracic duct passes up on the left side of the esophagus to drain into the commencement of the left innominate vein. A smaller duct, the right lymph duct, drains the right side of the head and neck and the right upper limb, entering the commencement of the right innominate vein (fig. 2). In addition, a number of other lymphatico-venous communications may occur irregularly in the thorax and abdomen. Lymph vessels coming from organs or limbs pass at some part of their course through one or more lymph nodes, and it must be rarely, if ever, that lymph reaches the venous system without passing through at least one node.

In certain fishes are seen vessels—venous lymphatics—which contain blood and lymph in varying proportions. In these animals

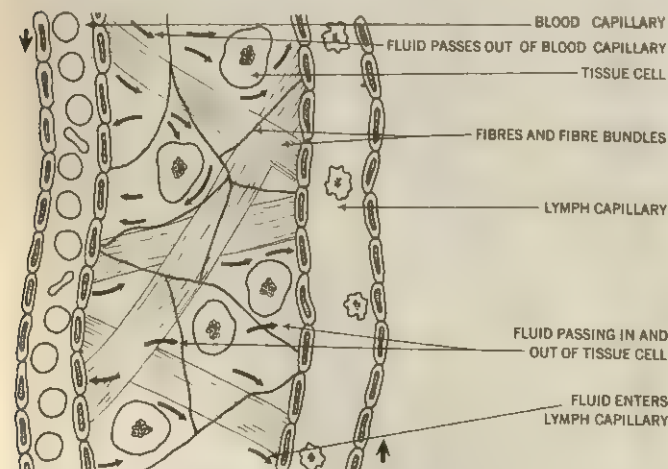

FIG. 1.—DIAGRAM SHOWING FLUID EXCHANGES TAKING PLACE IN ACTIVE TISSUE.

Arrows indicate the direction of flow of the fluid as it comes from the blood vessels and passes between the tissue cells into the lymph capillary, where it forms lymph. Arrows also indicate fluid exchange between the cells and surrounding tissue fluid.

FIG. 2.—SCHEME OF THE MAIN LYMPH VESSELS IN MAMMALS

the lymph vessels do not possess valves, and fluid is driven through them by contractile lymph hearts. In amphibia and reptiles lymph is no longer mixed with blood; lymphatic valves have not yet appeared, but functional lymph hearts are present, to effect a sluggish but direct flow of lymph to the blood. In most birds the lymph hearts disappear after embryonic life and the lymph vessels contain valves, just as do those of mammals.

2. Composition of Lymph.—Lymph is the colourless or yellowish fluid, containing formed elements, salts and varying amounts of protein and fat, which fills the lymphatic vessels. There is general agreement that the crystalloids of lymph are substantially identical with those of the tissue fluid. Like it, they consist chiefly of the cations: sodium, potassium, calcium and magnesium; and the anions: chloride, bicarbonate and phosphate. C. K. Drinker and his associates brought forward considerable evidence that this identity with the tissue fluid extends to the protein content also; i.e., that peripheral lymph can fairly be regarded as the counterpart of tissue fluid, which undergoes little if any modification as it crosses the extremely permeable lymphatic endothelium.

Lymph derived from the intestine differs from lymph in other situations, since it is intimately associated with the absorption of several substances. If the animal has been fed some time previously with a fatty meal, the lymph has a milky appearance which is due to the presence of innumerable fine droplets of fat (chylomicrons) about $0.5\mu-0.75\mu$ in diameter. The fat is absorbed by the lymphatics of the small intestine, which because of their white appearance during digestion are called lacteals. Among other substances known to be absorbed from the intestine via the lymphatics are vitamin K and certain sterols.

3. Amount of Lymph.—No precise data are available on the total lymph flow. Most of the information is based on thoracic duct lymph flow in anesthetized animals, and from this it would appear that the flow is about 2 ml. per kilogram per hour in nonruminants, and rather more than this in ruminants. The flow of lymph in all the other ducts combined is about 50% of the thoracic duct flow. Direct measurements had not been made in man, except for a few diseased persons in whom the flow ranged from 0.3 l. to 2.8 l. a day. The total volume of all the lymph in the lymphatics and lymphoid tissues at any given time cannot be accurately determined.

4. Relation of Lymph to Lymphoid Tissue.—In the lymph glands the lymphoid tissue is traversed by a lymph stream which reaches the glands by afferent lymph vessels and leaves them by efferent vessels. The subepithelial lymphoid tissue (nasal)

pharyngeal and intestinal, as also the thymus) possesses efferent but not afferent vessels. The lymphoid tissue of the spleen is related to the blood stream and possesses neither afferent nor efferent lymph vessels. In the case of lymph glands, lymph which has not yet traversed a gland is known as peripheral lymph. If it has passed through one gland but still has to flow through another, it is intermediate lymph, while if it is on its way to the blood without further glandular interruption it is central lymph.

5. Formed Elements in Lymph.—The majority of the white cells in central lymph are lymphocytes, of which about 95% are small or medium lymphocytes and 5% large basophilic cells, capable of mitosis (*i.e.*, cell division). A few monocytes and granulocytes may be present. Most studies of central lymph have been made on lymph from the thoracic duct. The actual number of cells present at any time is quite variable, both in the same and in different species. In general, the smaller the animal, the greater the concentration of lymphocytes. In the dog and cat J. M. Yoffey and C. K. Drinker found that peripheral lymph contained a mean lymphocyte count of 280 and 370 per cubic millimetre, while thoracic duct lymph contained 7,800 and 12,000 lymphocytes per cubic millimetre, respectively. The lymphocyte count in thoracic duct lymph may on occasion greatly exceed this figure. Peripheral lymph contains small numbers of red and white cells, while central and intermediate lymph contain large numbers of white cells, almost entirely lymphocytes, which are being carried in the lymph to the blood stream.

6. Mode of Production of Lymph.—The forces subserving the transference of substances through the blood capillary wall to the lymphatic vessels appear to be of a physical character, though the capillary endothelium, being composed of living cells, is capable of altering its degree of permeability. It appears to be at all times freely permeable to dissolved salts, but its permeability to protein is variable. The physiological conditions under which this permeability alters are not known, but under various pathological conditions the proteins are able to pass freely through the injured epithelium, as also are the formed elements of the blood in lesser degree.

It is now considered that there are three forces producing a transference of fluid and dissolved substances from the interior of the capillary to the tissue spaces; they are blood pressure, diffusion and osmosis. The excess hydrostatic pressure existing in a blood capillary over that in the extravascular tissue spaces causes a filtration through the endothelial wall of fluid with the same composition in salts as blood but varying in protein content. At the same time diffusible substances at a greater concentration in the blood tend to pass to a region of lesser concentration in the tissues. The third force, that of osmosis, depends on the fact that water passes through the capillary more quickly than salts and even more quickly in relation to the plasma proteins. Thus if a hypertonic solution of sodium chloride is injected intravenously there is a passage of water from the tissues to the blood, which becomes greatly increased in volume, with a concomitant desiccation of the tissues. At the same time salt passes more slowly from the blood into the tissues until a new equilibrium is reached. In the reverse direction similar changes would follow an increased molecular concentration in the tissues. These factors would be sufficient to account for the major part of the exchange of water and dissolved substances between blood and tissues.

Osmotic pressure of the plasma proteins, however (as first clearly pointed out by E. H. Starling in 1896), is essential for maintaining the full balance of fluid exchange through the capillary membrane. According to what is now known as the Starling hypothesis, the endothelium of the blood capillary functions as a semipermeable membrane in relation to the plasma proteins. At any given time the amount of plasma protein which leaks through the capillary wall is small in relation to that which does not, and the protein within the capillary exerts an osmotic pressure of about 30–40 mm. Hg (mercury). There are thus two opposed forces. The capillary pressure causes water to pass out of the capillary into the tissues, while the osmotic pressure of the plasma proteins causes it to be absorbed from the tissues into the capillary. The most important of the plasma proteins for this purpose

is the albumin, which has a molecular weight of 69,000. "Whereas capillary pressure determines transudations the osmotic pressure of the proteids of the serum determines absorption." The truth of Starling's hypothesis was confirmed by direct measurement of the pressure changes in individual capillaries in the frog's mesentery (E. M. Landis, 1927). Later J. R. Pappenheimer and A. Soto-Rivera (1948), using an isolated mammalian hindleg preparation, showed that the same was true for mammalian capillaries and that, in respect of the absolute figures for the capillary pressure and the osmotic pressure of the plasma proteins, the rate of fluid transfer depended on the net difference between these two forces.

A number of additional factors, though they do not affect the essential validity of Starling's view, call for consideration. Thus there is some protein in the tissue fluid and it exerts an osmotic pressure in the opposite direction to the plasma proteins. The effective osmotic pressure of the plasma proteins is therefore lessened by this amount. Furthermore, Landis showed by direct measurement that there is a fall in pressure from the arterial to the venous end of the capillary, with corresponding differences in the final fluid exchange. It is estimated that at the arterial end of the capillary the hydrostatic pressure is greater than the osmotic, whereas at the venous end it is lower. At the arterial end, therefore, the excess of hydrostatic pressure causes fluid to flow from the capillary to the tissue spaces. At the venous end the excess of osmotic pressure produces the reverse phenomenon and fluid passes from the tissue spaces into the capillary. The difference between the two ends may be diminished, however, by the fact that, as first suggested by F. P. Rous, the permeability of the blood capillary is not the same throughout its length, but exhibits a gradient, increasing from the arterial to the venous end.

The balance between the forces controlling fluid exchange is very nicely regulated, and it is possible that if it were not for the leakage of protein, lymphatics would be quite unnecessary. There are regions of the body in which, when at rest, the lymphatic system plays very little part, so that a constant interchange between blood and tissue fluid can take place without the production of a single drop of lymph. If a cannula is inserted into the main lymph trunk of a limb at rest almost no lymph can be obtained. If, however, the limb is thrown into action, the arterioles and capillaries of the part dilate and the hydrostatic pressure in them consequently increases; that is to say, the length of the capillary in which resorption can occur, by virtue of the excess of osmotic over hydrostatic pressure, is lessened so that fluid tends to accumulate in the tissue spaces. That it does not normally accumulate there is due to the fact that it is taken away by the lymphatics. It must be emphasized, however, that the lymphatic vessels cannot deal with large quantities of fluid and if there is more than a moderate increase in the escape of fluid from the blood capillaries, it accumulates in the tissues, which become waterlogged and edematous.

7. Structure and Properties of Blood Capillary Endothelium.—The formation and drainage of lymph involve the passage of fluid first through the endothelium of the blood capillary and second through that of the lymphatic capillary. The lymphatic capillaries appear to consist solely of cells joined by intercellular cement. The blood capillary has the same essential structure, but in addition there is usually a pericapillary sheath of fine connective tissue, while on the inner surface of the endothelium there may be a noncellular lining derived from the plasma proteins (R. Chambers and B. W. Zweifach, 1947). The intercellular cement is readily demonstrated in most capillaries by the reduction of silver nitrate. It may well be that the cement lines constitute areas of increased permeability. Electron microscope studies suggest that true capillary pores may in fact exist in certain situations.

The distinctive feature of lymphatic endothelium is its great permeability. Not only large protein molecules but even solid particles such as india ink, bacteria and cells pass through it readily. This fact is the basis of the classical method of demonstrating lymphatics, namely, interstitial injection—the injection of a particulate suspension into the tissue spaces or interstices, whence the particles readily enter the adjacent capillaries. This
